CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

SINES.

SINE, or *Right Sine*, in *Trigonometry*, a right line drawn from one extremity of an arc, perpendicular to the radius drawn from the other extremity: or, the ſine is half the chord of twice the arc.

Thus the line A D (*Plate* I. *Trigonometry*, *fig*. 4.) which is half the chord, A B, of the double arc A E B, is the right ſine; or, ſimply, the ſine of the arc A E.

Sine, *Whole*, *Sinus totus*, is the ſine of the quadrant H E, or of 90°; that is, the whole ſine is the ſame with the radius H C.

Sine, *Verſed*, is a part, E D, of the whole ſine or radius intercepted between the right ſine A D and the arc A E.

It is demonſtrated, 1. That, the right ſine A D being perpendicular to the radius E C, all ſines drawn to the ſame radius are parallel to each other.

2. Since the arc A E is the meaſure of the angle A C E, and A I the meaſure of the contiguous angle A C I, and the quadrant H E the meaſure of the right angle; A D is alſo the right ſine, and E D the verſed ſine, of the angles A C E and A C I, and the whole ſine is the ſine of the right angle.

3. Two angles contiguous, as A C E and A C I, have the ſame ſine.

4. The ſines of obtuſe angles are the ſame with thoſe of their complements to two right angles: or the ſine of any angle, and the ſine of its ſupplement, are the ſame; or the ſines of arcs leſs than 90°, ſerve equally for arcs as much greater than 90°; *i. e.* the ſines of 80° and 100°, of 60° and 120°, &c. are reſpectively equal.

5. All ſines of ſimilar arcs have the ſame ratio to their radii.

6. In every triangle the ſides are as the ſines of the oppoſite angles.

Sine-*Complement*, or *Coſine*, is the ſine of an arc A E, which is the complement of another arc A H, to a quadrant.

Thus alſo the ſine of the arc A H is called the *ſine-complement* of the arc A E. And it is plain, that the *verſed ſine* and *coſine*, taken together, are equal to the radius.

The ſine D E (*fig*. 10.) *and the verſed ſine* A E, *being given in common meaſure, not in parts of the radius, to find the arc* D A *in degrees.* Find the ſemidiameter A C: then in the triangle D E C, beſides the right angle E, by the ſides D E and D C we find the angle E C D (A C D), which ſhews the number of degrees in the arc D A; the double of which is the arc D A D. This problem is of uſe in finding the ſegment of a circle. See Segment.

Arithmetic of Sines is a term commonly employed to denote what is perhaps more properly called *analytical trigonometry*, being a modern branch of the analytical calculus, which we owe in a great meaſure to the celebrated Euler, though the principal geometrical theorem on which it is founded was firſt pointed out by Mayer, in a memoir publiſhed in the Acta Petro. for 1727; but the extenſion of the method, and a ſuitable mode of notation, are undoubtedly due to Euler.

The object of this branch of ſcience is to exhibit the relations of the ſines, coſines, tangents, cotangents, &c. of arcs, multiple arcs, &c.; and it is, without doubt, owing, in ſome meaſure, to the facilities this calculus has afforded, of expreſſing in a ſimple manner formulæ, which, without its aid, would have exceeded the powers of the human mind, that aſtronomy, which depends ſo much on theſe relations, has attained its preſent high degree of perfection.

In common arithmetic, our object is to combine together different ſimple numbers, by addition, multiplication, &c.;

Printed by A. Strahan,
New Street Square, London.

Or they may be reduced to two, by means of the double ſign $\pm$, thus:

$$1.\ \text{ſin.}\,(a \pm b) = \text{ſin.}\,a\,.\,\text{coſ.}\,b \pm \text{ſin.}\,b\,.\,\text{coſ.}\,a.$$

$$2.\ \text{coſ.}\,(a \pm b) = \text{coſ.}\,a\,.\,\text{coſ.}\,b \mp \text{ſin.}\,a\,.\,\text{ſin.}\,b.$$

In order to find ſimilar formulæ for the tangents, cotangents, ſecants, coſecants, &c. we may put our ſecond expreſſion under the form,

$$\text{coſ.}\,(a \pm b) = \left(1 \mp \frac{\text{ſin.}\,a\,.\,\text{ſin.}\,b}{\text{coſ.}\,a\,.\,\text{coſ.}\,b}\right) \text{coſ.}\,a\,.\,\text{coſ.}\,b.$$

And if now we divide formula 1 by this, we have, by obſerving that $\frac{\text{ſin.}\,a}{\text{coſ.}\,a} = \text{tan.}\,a$,

$$3.\ \text{tan.}\,(a \pm b) = \frac{\text{tan.}\,a \pm \text{tan.}\,b}{1 \mp \text{tan.}\,a\,.\,\text{tan.}\,b}.$$

$$4.\ \text{cot.}\,(a \pm b) = \frac{\text{cot.}\,a\,.\,\text{cot.}\,b \mp 1}{\text{cot.}\,b \pm \text{cot.}\,a};$$

the latter being obtained by dividing the ſecond formula by the firſt.

Again, taking the reciprocal of formula 2, we have

$$\frac{1}{\text{coſ.}\,(a \pm b)} = \frac{1}{1 \mp \text{tan.}\,a\,.\,\text{tan.}\,b}\,.\,\frac{1}{\text{coſ.}\,a\,.\,\text{coſ.}\,b};\ \text{or,}$$

$$5.\ \text{ſec.}\,(a \pm b) = \frac{\text{ſec.}\,a\,.\,\text{ſec.}\,b}{1 \mp \text{tan.}\,a\,.\,\text{tan.}\,b}.$$

$$6.\ \text{coſ.}\,(a \pm b) = \frac{\text{coſec.}\,a\,.\,\text{coſec.}\,b}{\text{cot.}\,b \pm \text{cot.}\,a}.$$

In like manner may be found,

$$7.\ \text{cho.}\,(a \pm b) = \text{cho.}\,a\,.\,\text{ſup. cho.}\,b \pm \text{cho.}\,b\,.\,\text{ſup. cho.}\,a.$$

$$8.\ \text{verſ.}\,(a \pm b) = \surd\,(\text{verſ.}\,a\,.\,\text{ſup. verſ.}\,b) \pm \surd\,(\text{verſ.}\,b\,.\,\text{ſup. verſ.}\,a).$$

The reader will find a different inveſtigation of theſe properties under the article *Geometry of* POSITION.

Let us now ſee how far theſe general formulæ will indicate the changes of ſigns in the trigonometrical lines, as connected with the ſeveral different magnitudes of their reſpective arcs; a ſubject that we have already conſidered geometrically.

Let π denote the ſemicircle, and let the arc $a = \frac{1}{2}\pi$; then becauſe $\text{ſin.}\,\frac{1}{2}\pi = 1$, and $\text{coſ.}\,\frac{1}{2}\pi = 0$, we have from

$$\begin{aligned}
&\text{Formula (1)}\ \text{ſin.}\,(\tfrac{1}{2}\pi + b) = +\,\text{coſ.}\,b.\\
&\phantom{\text{Formula }}(2)\ \text{coſ.}\,(\tfrac{1}{2}\pi + b) = -\,\text{ſin.}\,b.\\
&\phantom{\text{Formula }}(3)\ \text{ſin.}\,(\tfrac{1}{2}\pi - b) = +\,\text{coſ.}\,b.\\
&\phantom{\text{Formula }}(4)\ \text{coſ.}\,(\tfrac{1}{2}\pi - b) = +\,\text{ſin.}\,b.
\end{aligned}$$

Here we obtain the ſame reſults as before deduced; that is, it is obvious from theſe, that if we conſider the ſine and coſine of an arc leſs than a quadrant as poſitive quantities, the coſine of an arc greater than a quadrant, but leſs than a ſemicircle, will be negative, but its ſine poſitive.

Again, let the arc $a = \pi$; then becauſe $\text{ſin.}\,\pi = 0$, $\text{coſ.}\,\pi = -1$, we have

$$\text{ſin.}\,(\pi + b) = -\,\text{ſin.}\,b;\ \text{coſ.}\,(\pi + b) = -\,\text{coſ.}\,b;$$
$$\text{ſin.}\,(\pi - b) = +\,\text{ſin.}\,b;\ \text{coſ.}\,(\pi - b) = -\,\text{coſ.}\,b.$$

Whence it follows, that the ſines of angles greater than a ſemicircle, but leſs than a circle, have negative ſigns; while thoſe that are leſs than a ſemicircle are poſitive: whereas the coſines of angles equally above and below the ſemicircle have the ſame ſigns.

If now we aſſume the arc $a = \frac{3}{2}\pi$; then, becauſe $\text{ſin.}\,\frac{3}{2}\pi = -1$, and $\text{coſ.}\,\frac{3}{2}\pi = 0$, we have

$$\text{ſin.}\,(\tfrac{3}{2}\pi + b) = -\,\text{coſ.}\,b;\ \text{coſ.}\,(\tfrac{3}{2}\pi + b) = +\,\text{ſin.}\,b;$$
$$\text{ſin.}\,(\tfrac{3}{2}\pi - b) = -\,\text{coſ.}\,b;\ \text{coſ.}\,(\tfrac{3}{2}\pi - b) = -\,\text{ſin.}\,b.$$

Therefore, when the arc is comprehended between $\frac{3}{2}\pi$, 2π, its coſine is poſitive, and its ſine negative. Theſe reſults have all been previouſly eſtabliſhed geometrically; but they are here very readily extended to any arcs expreſſed by $\frac{n}{2}\pi \pm b$; n being any number whatever. Theſe are all contained in the following general formulæ, *viz.*

$$\text{ſin.}\left(\frac{4n+1}{2}\pi \pm b\right) = +\,\text{coſ.}\,b.$$

$$\text{ſin.}\left(\frac{4n+2}{2}\pi \pm b\right) = \mp\,\text{ſin.}\,b.$$

$$\text{ſin.}\left(\frac{4n+3}{2}\pi \pm b\right) = -\,\text{coſ.}\,b.$$

$$\text{ſin.}\left(\frac{4n+4}{2}\pi \pm b\right) = \pm\,\text{ſin.}\,b.$$

$$\text{coſ.}\left(\frac{4n+1}{2}\pi \pm b\right) = \mp\,\text{ſin.}\,b.$$

$$\text{coſ.}\left(\frac{4n+2}{2}\pi \pm b\right) = -\,\text{coſ.}\,b.$$

$$\text{coſ.}\left(\frac{4n+3}{2}\pi \pm b\right) = \pm\,\text{ſin.}\,b.$$

$$\text{coſ.}\left(\frac{4n+4}{2}\pi \pm b\right) = +\,\text{coſ.}\,b.$$

Hence it follows, that there is an indefinite number of arcs that have the ſame ſine and coſine, as alſo the ſame ſecant and tangent; the conditions of which latter are readily deduced from the above, by means of the formula $\text{tan.}\,a = \frac{\text{coſ.}\,a}{\text{ſin.}\,a}$, $\text{cot.}\,a = \frac{\text{ſin.}\,a}{\text{coſ.}\,a}$, $\text{ſec.}\,a = \frac{1}{\text{coſ.}\,a}$, &c.

For ſince $\text{tan.}\,a = \frac{\text{ſin.}\,a}{\text{coſ.}\,a}$, and $\text{cotan.}\,a = \frac{\text{coſ.}\,a}{\text{ſin.}\,a}$, it follows, that the tangent will be poſitive, while ſin. a and coſ. a have the ſame ſigns; and negative, when the ſigns are different; and the ſame alſo with the cotangents: theſe are, therefore, both poſitive in the firſt and third quadrants, and negative in the ſecond and fourth. Alſo the tangent is infinite when the coſ. $= 0$, and cotangent infinite when ſin. $= 0$. Again, ſince $\text{ſec.}\,a = \frac{1}{\text{coſ.}\,a}$, and $\text{coſec.}\,a = \frac{1}{\text{ſin.}\,a}$, it follows that theſe lines have the ſame ſigns as the coſ. and ſin. reſpectively; and that the ſecant is infinite when coſ. $= 0$, and the coſec. infinite when ſin. $= 0$.

Having thus ſhewn the relations between the ſeveral trigonometrical lines, their mutations and determinate values, under certain magnitudes of the arcs to which they appertain, we ſhall proceed in the next place to inveſtigate ſome of the principal formulæ for the ſines, coſines, &c. of multiple arcs.

SINES.

Of Multiple Arcs.

By referring to our formula (I), we have

$$\text{ſin.}\ (a+b) = \text{ſin.}\ a\ .\ \text{coſ.}\ b + \text{ſin.}\ b\ .\ \text{coſ.}\ a;$$

which, by writing $(n-1)\,a$ for a, and a for b, becomes

$$\text{ſin.}\ n\,a = \text{ſin.}\ (n-1)\,a\ .\ \text{coſ.}\ a + \text{coſ.}\ (n-1)\,a\ .\ \text{ſin.}\ a.$$

By ſubſtituting in this formula for ſin. $(n-1)\,a$, and coſ. $(n-1)\,a$, under the form

$$\text{ſin.}\ \left\{(n-2)\,a + a\right\} \text{ and coſ. } \left\{(n-1)\,a + a\right\}, \text{ we obtain}$$

$$\begin{aligned}\text{ſin.}\ n\,a = {} & \left\{\text{ſin.}\ (n-2)\ .\ \text{coſ.}\ a + \text{coſ.}\ (n-2)\,a\ .\ \text{ſin.}\ a\right\}\ \text{coſ.}\ a \\ & + \left\{\text{coſ.}\ (n-2)\,a\ .\ \text{coſ.}\ a - \text{ſin.}\ (n-2)\,a\ .\ \text{ſin.}\ a\right\}\ \text{ſin.}\ a\end{aligned}$$

Subſtituting here again for $(n-2)\,a$, under the form $(n-3)\,a + a$, and obſerving that the ſecond term of the firſt line is the ſame as the firſt of the ſecond, we have

$$\begin{aligned}\text{ſin.}\ n\,a = {} & \left\{\text{ſin.}\ (n-3)\,a\ .\ \text{coſ.}\ a + \text{coſ.}\ (n-3)\,a\ .\ \text{ſin.}\ a\right\}\ \text{coſ.}^2\ a \\ & + 2\left\{\text{coſ.}\ (n-3)\,a\ .\ \text{coſ.}\ a - \text{ſin.}\ (n-3)\,a\ .\ \text{ſin.}\ a\right\}\ \text{coſ.}\ a\ .\ \text{ſin.}\ a \\ & - \left\{\text{ſin.}\ (n-3)\,a\ .\ \text{coſ.}\ a + \text{coſ.}\ (n-3)\,a\ .\ \text{ſin.}\ a\right\}\ \text{ſin.}^2\ a\end{aligned}$$

$$= \text{ſin.}\ (n-3)\,a\ .\ \text{coſ.}^3\ a + 3\ \text{coſ.}\ (n-3)\,a\ .\ \text{coſ.}^2\ a\ .\ \text{ſin.}\ a - 3\ \text{ſin.}\ (n-3)\,a\ \text{coſ.}\ a\ .\ \text{ſin.}^2\ a - \text{coſ.}\ (n-3)\,a\ .\ \text{ſin.}^3\ a;$$

the laſt term of each of thoſe lines being ſtill the ſame as the firſt term of the following; and therefore, without purſuing the operation any farther, the law of continuation is obvious; *viz.* the ſeveral coefficients will be exactly thoſe of the binomial; but the ſigns will be two *plus* and two *minus* alternately, whence generally

$$\text{ſin.}\ n\,a = \text{ſin.}\ (n-m)\,a\ .\ \text{coſ.}^m\ a + \text{A}\ \text{coſ.}\ (n-m)\,a\ .\ \text{coſ.}^{m-1}\ a\ \text{ſin.}\ a - \text{B}\ \text{ſin.}\ (n-m)\,a\ .\ \text{coſ.}^{m-2}\ a\ \text{ſin.}^2\ a - \text{C}\ \text{coſ.}\ (n-m)\,a\ \text{coſ.}^{m-3}\ a\ .\ \text{ſin.}^3\ a + \&\text{c.}$$

where A, B, C, &c. are the coefficients of $(1+1)^m$.

And exactly in the ſame manner, we find

$$\text{coſ.}\ n\,a = \text{coſ.}\ (n-m)\,a\ .\ \text{coſ.}^m\ a - \text{A}\ \text{ſin.}\ (n-m)\,a\ \text{coſ.}^{m-1}\ a\ \text{ſin.}\ a - \text{B}\ \text{coſ.}\ (n-m)\,a\ .\ \text{coſ.}^{m-2}\ a\ .\ \text{ſin.}^2\ a + \text{C}\ \text{ſin.}\ (n-m)\,a\ .\ \text{coſ.}^{m-3}\ a\ .\ \text{ſin.}^3\ a + \&\text{c.}$$

In theſe formulæ m is indeterminate, and may be aſſumed at pleaſure; let us therefore take $m = n$, and we have

$$\text{ſin.}\ n\,a = \text{A}\ \text{coſ.}^{n-1}\ a\ .\ \text{ſin.}\ a - \text{C}\ \text{coſ.}^{n-3}\ a\ .\ \text{ſin.}^3\ a + \text{E}\ \text{coſ.}^{n-5}\ a\ .\ \text{ſin.}^5\ a - \&\text{c.} \quad \text{(II.)}$$

and

$$\text{coſ.}\ n\,a = \text{coſ.}^n\ a - \text{B}\ \text{coſ.}^{n-2}\ a\ .\ \text{ſin.}^2\ a + \text{D}\ \text{coſ.}^{n-4}\ a\ .\ \text{ſin.}^4\ a - \&\text{c.} \qquad \text{(III.)}$$

where A, B, C, &c. repreſent the coefficients of $(1+1)^n$.

From theſe two general formulæ we readily deduce the following particular caſes; *viz.*

1. $\text{ſin.}\ a = 1\ \text{ſin}\ a$
2. $\text{ſin.}\ 2\,a = 2\ \text{coſ.}\ a\ .\ \text{ſin.}\ a$
3. $\text{ſin.}\ 3\,a = 3\ \text{coſ.}^2\ a\ .\ \text{ſin.}\ a - \text{ſin.}^3\ a$
4. $\text{ſin.}\ 4\,a = 4\ \text{coſ.}^3\ a\ .\ \text{ſin.}\ a - 4\ \text{coſ.}\ a\ \text{ſin.}^3\ a$
5. $\text{ſin.}\ 5\,a = 5\ \text{coſ.}^4\ a\ .\ \text{ſin.}\ a - 10\ \text{coſ.}^2\ a\ \text{ſin.}^3\ a + \text{ſin.}^5\ a$

&c. = &c.

1. $\text{coſ.}\ a = \text{coſ.}\ a$
2. $\text{coſ.}\ 2\,a = \text{coſ.}^2\ a - \text{ſin.}^2\ a$
3. $\text{coſ.}\ 3\,a = \text{coſ.}^3\ a - 3\ \text{coſ.}\ a\ .\ \text{ſin.}^2\ a$
4. $\text{coſ.}\ 4\,a = \text{coſ.}^4\ a - 6\ \text{coſ.}^2\ a\ .\ \text{ſin.}^2\ a + \text{ſin.}^4\ a$
5. $\text{coſ.}\ 5\,a = \text{coſ.}^5\ a - 10\ \text{coſ.}^3\ a\ .\ \text{ſin.}^2\ a + 5\ \text{coſ.}\ a\ .\ \text{ſin.}^4\ a$

&c. = &c.

Theſe, it is obvious, may be continued at pleaſure, the law of the coefficients being exhibited in the above general formulæ.

or, $$\text{ſin.}\, n\, a = \left\{2^{n-1} - \frac{n-2}{1} \cdot 2^{n-3}\, \text{ſec.}^2 a + \frac{(n-3)(n-4)}{1 \cdot 2} \cdot 2^{n-5}\, \text{ſec.}\, a\right\} \frac{1}{\text{ſec.}^{n-1} a \cdot \text{coſec.}\, a}$$

$$\text{coſ.}\, n\, a = \left\{2^{n-1} - n \cdot 2^{n-3}\, \text{ſec.}^2 a + \frac{n(n-3)}{1 \cdot 2} \cdot 2^{n-5}\, \text{ſec.}^4 a - \&\text{c.}\right\} \frac{1}{\text{ſec.}^n a}$$

The reciprocal of the latter gives,

$$\text{ſec.}\, n\, a = \frac{\text{ſec.}^n a}{2^{n-1} - n \cdot 2^{n-3}\, \text{ſec.}^2 a + \frac{n(n-3)}{1 \cdot 2} \cdot 2^{n-5}\, \text{ſec.}^4 a - \&\text{c.}} \qquad \text{(XII.)}$$

And the reciprocal of the former,

$$\text{coſec.}\, n\, a = \frac{\text{ſec.}^{n-1} a \cdot \text{coſec.}\, a}{2^{n-1} - \frac{n-2}{1}\, 2^{n-3}\, \text{ſec.}^2 a + \frac{(n-3)(n-4)}{1 \cdot 2} \cdot 2^{n-5}\, \text{ſec.}^4 a - \&\text{c.}} \qquad \text{(XIII.)}$$

From theſe we draw the following particular caſes :

1. $\text{ſec.}\, a = \text{ſec.}\, a$	1. $\text{coſec.}\, a = \text{coſec.}\, a$
2. $\text{ſec.}\, 2\, a = \frac{\text{ſec.}^2 a}{2 - \text{ſec.}^2 a}$	2. $\text{coſec.}\, 2\, a = \frac{\text{ſec.}\, a \cdot \text{coſec.}\, a}{2}$
3. $\text{ſec.}\, 3\, a = \frac{\text{ſec.}^3 a}{4 - 3\, \text{ſec.}^2 a}$	3. $\text{coſec.}\, 3\, a = \frac{\text{ſec.}^2 a \cdot \text{coſec.}\, a}{4 - \text{ſec.}^2 a}$
4. $\text{ſec.}\, 4\, a = \frac{\text{ſec.}^4 a}{8 - 8\, \text{ſec.}^2 a + \text{ſec.}^4 a}$	4. $\text{coſec.}\, 4\, a = \frac{\text{ſec.}^3 a\; \text{coſec.}\, a}{8 - 4\, \text{ſec.}^2 a}$
5. $\text{ſec.}\, 5\, a = \frac{\text{ſec.}^5 a}{16 - 20\, \text{ſec.}^2 a + 5\, \text{ſec.}^4 a}$	5. $\text{coſec.}\, 5\, a = \frac{\text{ſec.}^4 a\; \text{coſec.}\, a}{16 - 12\, \text{ſec.}^2 a + \text{ſec.}^4 a}$
&c. = &c.	&c. = &c.

Theſe latter formulæ have the ſame defect as thoſe of the ſines from which they are derived ; *viz.* that both the ſecant and coſecant of the ſingle arc enter in the general expreſſion for the coſecant of the multiple arc.

We ſhall not inveſtigate the formula for the multiple verſed ſine, but ſhall content ourſelves with merely exhibiting the reſult, which is as follows :

$$\text{verſ.}\, n a = n^2\, \text{verſ.}\, a - \frac{n^2 - 1}{2 \cdot 3}\, (\text{A})\, \text{verſ.}^2 a - \frac{n^2 - 2^2}{3 \cdot 5}\, (\text{B})\, \text{verſ.}^3 a - \frac{n^2 - 3^2}{4 \cdot 7}\, (\text{C})\, \text{verſ.}^4 a - \&\text{c.}$$

where A, B, C, &c. are the coefficients of the preceding terms.

A variety of other formulæ for multiple arcs might be here inveſtigated, but our limits forbid a farther extenſion ; thoſe which we have given above are chiefly exhibited by means of the powers of the ſingle arc ; a few others, in the form of continued products, may be here enumerated, but we muſt not attempt their inveſtigation.

Let π denote the ſemicircumference, and we ſhall have

$$\text{ſin.}\, n a = 2^{n-1} \cdot \text{ſin.}\, a \cdot \text{ſin.}\left(\frac{\pi}{n} - a\right) \cdot \text{ſin.}\left(\frac{\pi}{n} + a\right) \cdot \text{ſin.}\left(\frac{2\pi}{n} - a\right) \cdot \text{ſin.}\left(\frac{2\pi}{n} + a\right) \cdot \text{ſin.}\left(\frac{3\pi}{n} - a\right) \cdot \text{ſin.}\left(\frac{3\pi}{n} + a\right)\ \&\text{c.}$$

$$\text{coſ.}\, n a = 2^{n-1}\, \text{coſ.}\left(\frac{n-1}{2n}\pi + a\right) \cdot \text{coſ.}\left(\frac{n-1}{2n}\pi - a\right) \cdot \text{coſ.}\left(\frac{n-3}{2n}\pi + a\right) \cdot \text{coſ.}\left(\frac{n-3}{2n}\pi - a\right) \cdot \text{coſ.}\left(\frac{n-5}{2n}\pi + a\right) \cdot \text{coſ.}\left(\frac{n-5}{2n}\pi - a\right)\ \&\text{c.}$$

$$\text{tan.}\, n a = \text{tan.}\, a \cdot \text{tan.}\left(\frac{\pi}{n} - a\right) \text{tan.}\left(\frac{\pi}{n} + a\right) \text{tan.}\left(\frac{2\pi}{n} - a\right) \text{tan.}\left(\frac{2\pi}{n} + a\right) \text{tan.}\left(\frac{3\pi}{n} - a\right) \text{tan.}\left(\frac{3\pi}{n} + a\right)\ \&\text{c.} \ldots \text{tan.}\left(\frac{n\pi}{2n} + a\right)$$

To theſe we add the following, which are very ſimple ; *viz.*

$$\text{ſin.}\, a + \text{ſin.}\,(a + b) + \text{ſin.}\,(a + 2b) + \text{ſin.}\,(a + 3b) + \&\text{c. } \textit{ad infinitum} = \frac{\text{coſ.}\,(a - \frac{1}{2}b)}{2\, \text{ſin.}\, \frac{1}{2}b} \text{ ; and}$$

$$\text{ſin.}\, a + \text{ſin.}\,(a + b) + \text{ſin.}\,(a + 2b) + \&\text{c. ſin.}\,(a + nb) = \frac{\text{ſin.}\,(a + \frac{1}{2}b)\, \text{ſin.}\, \frac{1}{2}(n + 1)\, b}{\text{ſin.}\, \frac{1}{2}b}$$

$$\text{coſ.}\, a + \text{coſ.}\,(a + b) + \text{coſ.}\,(a + 2b) + \text{coſ.}\,(a + 3b) + \&\text{c. } \textit{ad infinitum} = -\frac{\text{ſin.}\,(a - \frac{1}{2}b)}{2\, \text{ſin.}\, \frac{1}{2}b}$$

$$\text{coſ.}\, a + \text{coſ.}\,(a + b) + \text{coſ.}\,(a + 2b) + \&\text{c. coſ.}\,(a + nb) = \frac{\text{coſ.}\,(a + \frac{1}{2}nb)\, \text{ſin.}\, \frac{1}{2}(n + 1)\, b}{\text{ſin.}\, \frac{1}{2}b}$$

Of

Of the Powers of the Sines, Coſines, &c. of ſingle Arcs.

In order to exhibit the powers of the ſine, coſine, &c. of the ſingle arcs, in terms of the ſines and coſines of the multiple arcs, we may refer to our formulæ (VIII) and (IX), *viz.*

$$2\,\text{coſ.}\ a = y + \frac{1}{y} \qquad\Big|\qquad (-1)^{\frac{1}{2}}\,.\,2\,\text{ſin.}\ a = y - \frac{1}{y}$$

$$2\,\text{coſ.}\ na = y^n + \frac{1}{y^n} \qquad\Big|\qquad (-1)^{\frac{1}{2}}\,.\,2\,\text{ſin.}\ na = y^n - \frac{1}{y^n}$$

From the firſt of theſe we have $2^n\,.\,\text{coſ.}^n a = \left(y + \frac{1}{y}\right)^n = y^n + \text{A}\,y^{n-2} + \text{B}\,y^{n-4} + \text{C}\,y^{n-6} + \&\text{c.}\ \text{A}\,\frac{1}{y^{n-2}} + \frac{1}{y^n}$ A, B, C, &c. repreſenting the binomial coefficients; or, collecting the terms from each extreme,

$$2^n\,\text{coſ.}^n a = \left(y^n + \frac{1}{y^n}\right) + \text{A}\left(y^{n-2} + \frac{1}{y^{n-2}}\right) + \text{B}\left(y^{n-4} + \frac{1}{y^{n-4}}\right) + \&\text{c. or,}$$

$$2^{n-1}\,\text{coſ.}^n a = \text{coſ.}\ na + n\,.\,\text{coſ.}\ (n-2)\ a + \frac{n\,.\,(n-1)}{1\,.\,2}\ \text{coſ.}\ (n-4)\ a + \&\text{c.} \qquad \text{(XIV.)}$$

It is only neceſſary to obſerve here, that when n is even, the number of terms in the original expanſion will be odd, and its middle term, into which no power of y enters, will form the laſt term of the latter ſeries; and having, therefore, no coſine in it, it will be only one-half of the coefficient given in the general term.

Whence the following particular caſes.

1. $\text{coſ.}\ a = \text{coſ.}\ a$
2. $2\,\text{coſ.}^2 a = \text{coſ.}\ 2\,a + 1$
3. $4\,\text{coſ.}^3 a = \text{coſ.}\ 3\,a + 3\,\text{coſ.}\ a$
4. $8\,\text{coſ.}^4 a = \text{coſ.}\ 4\,a + 4\,\text{coſ.}\ 2\,a + 3$
5. $16\,\text{coſ.}^5 a = \text{coſ.}\ 5\,a + 5\,\text{coſ.}\ 3\,a + 10\,\text{coſ.}\ a$

&c. = &c.

For the ſines, we have $(-1)^{\frac{n}{2}}.\,2^n\,.\,\text{ſin.}^n a = \left(y - \frac{1}{y}\right)^n = y^n - \text{A}\,y^{n-2} + \text{B}\,y^{n-4} - \text{C}\,y^{n-6} + \&\text{c.} \pm \frac{1}{y^n}$, the laſt ſign being + when n is *even*, but − when n is *odd*. Collecting the terms from the two extremes, we have firſt, *when n is even,*

$$(-1)^{\frac{n}{2}}\,.\,2^n\,.\,\text{ſin.}^n a = \left(y^n + \frac{1}{y^n}\right) - \text{A}\left(y^{n-2} + \frac{1}{y^{n-2}}\right) + \text{B}\left(y^{n-4} + \frac{1}{y^{n-4}}\right) - \&\text{c. or,}$$

$$(-1)^{\frac{n}{2}}\,.\,2^{n-1}\,.\,\text{ſin.}^n a = \text{coſ.}\ n\,a - n\,\text{coſ.}\ (n-2)\ a + \frac{n\,(n-1)}{1\,.\,2}\ \text{coſ.}\ (n-4)\ a - \&\text{c.} \qquad \text{(XV.)}$$

obſerving here the ſame as above in reſpect to n, an even number; and *when n is odd,*

$$(-1)^{\frac{n}{2}}\,.\,2^n\ \text{ſin.}^n a = \left(y^n - \frac{1}{y^n}\right) - \text{A}\left(y^{n-2} - \frac{1}{y^{n-2}}\right) + \text{B}\left(y^{n-4} - \frac{1}{y^{n-4}}\right) - \&\text{c. or}$$

$$(-1)^{\frac{n-1}{2}}\,.\,2^{n-1}\,.\,\text{ſin.}^n a = \text{ſin.}\ n\,a - n\ \text{ſin.}\ (n-2)\ a + \frac{n\,(n-1)}{1\,.\,2}\ \text{ſin.}\ (n-4)\,a - \&\text{c.} \qquad \text{(XVI.)}$$

Obſerving now the change of ſign, which takes place in the imaginary coefficient $(-1)^{\frac{n}{2}}$ and $(-1)^{\frac{n-1}{2}}$, according as n is of the form $4\,m$, $4\,m + 1$, $4\,m + 2$, or $4\,m + 3$, we draw from the above two formulæ the following particular reſults *viz.*

1. $1\ \text{ſin.}\ a = +\ \text{ſin.}\ a$
2. $2\ \text{ſin.}^2 a = -\ \text{coſ.}\ 2\,a - 1$
3. $4\ \text{ſin.}^3 a = -\ \text{ſin.}\ 3\,a + 3\ \text{ſin.}\ a$
4. $8\ \text{ſin.}^4 a = +\ \text{coſ.}\ 4\,a - 4\ \text{coſ.}\ 2\,a + 3$
5. $16\ \text{ſin.}^5 a = +\ \text{ſin.}\ 5\,a - 5\ \text{ſin.}\ 32 + 10\ \text{ſin.}\ a$

&c- = &c.

We muſt now come to a concluſion of our inveſtigations relative to the doctrine of ſines; had our limits admitted of it, we might have carried them to a much greater extent, but the above will be ſufficient for illuſtrating the principles of the moſt important and uſeful transformations; and the following reſults, which would occupy too much ſpace to develope, but which at the ſame time are too important to be paſſed over unnoticed, the reader will be able to deduce, with facility, from the formulæ drawn from our general expreſſion, (No. I.) and many others equally curious may be ſeen in Cagnoli's "Traité de Trigonometrie;" vol. i. of Euler's "Analyſis Infinitorum;" Bonnycaſtle's and Keith's Treatiſes of Trigonometry, &c. &c.

The formulæ to which we have above referred are the following.

Miſcellaneous Formulæ of frequent Application in the Arithmetic of Sines.

1. $\text{ſin.}\ a\ .\ \text{coſ.}\ b = \frac{1}{2}\,\text{ſin.}\ (a + b) + \frac{1}{2}\,\text{ſin.}\ (a - b)$
2. $\text{coſ.}\ a\ .\ \text{ſin.}\ b = \frac{1}{2}\,\text{ſin.}\ (a + b) - \frac{1}{2}\,\text{ſin.}\ (a - b)$
3. $\text{ſin.}\ a\ .\ \text{ſin.}\ b = \frac{1}{2}\,\text{coſ.}\ (a \backsim b) - \frac{1}{2}\,\text{coſ.}\ (a + b)$

4. $\text{coſ.}\, a \,.\, \text{coſ.}\, b = \frac{1}{2}\text{coſ.}\,(a+b) + \frac{1}{2}\text{coſ.}\,(a \backsim b)$

5. $\text{ſin.}\, a + \text{ſin.}\, b = 2\,\text{ſin.}\,\frac{1}{2}(a+b) \,.\, \text{coſ.}\,\frac{1}{2}(a \backsim b)$

6. $\text{coſ.}\, a + \text{coſ.}\, b = 2\,\text{coſ.}\,\frac{1}{2}(a+b) \,.\, \text{coſ.}\,\frac{1}{2}(a \backsim b)$

7. $\text{tan.}\, a + \text{tan.}\, b = \dfrac{\text{ſin.}\,(a+b)}{\text{coſ.}\, a \,.\, \text{coſ.}\, b}$

8. $\text{cot.}\, a + \text{cot.}\, b = \dfrac{\text{ſin.}\,(a+b)}{\text{ſin.}\, a \,.\, \text{ſin.}\, b}$

9. $\text{ſin.}\, a - \text{ſin.}\, b = 2\,\text{ſin.}\,\frac{1}{2}(a-b) \,.\, \text{coſ.}\,\frac{1}{2}(a+b)$

10. $\text{coſ.}\, a \backsim \text{coſ.}\, b = 2\,\text{ſin.}\,\frac{1}{2}(a-b) \,.\, \text{ſin.}\,\frac{1}{2}(a+b)$

11. $\text{tan.}\, a - \text{tan.}\, b = \dfrac{\text{ſin.}\,(a-b)}{\text{coſ.}\, a \,.\, \text{coſ.}\, b}$

12. $\text{cot.}\, a \backsim \text{cot.}\, b = \dfrac{\text{ſin.}\,(a-b)}{\text{ſin.}\, a \,.\, \text{ſin.}\, b}$

13. $\dfrac{\text{ſin.}\,(a+b)}{\text{ſin.}\,(a-b)} = \dfrac{\text{tan.}\, a + \text{tan.}\, b}{\text{tan.}\, a - \text{tan.}\, b} = \dfrac{\text{cot.}\, a + \text{cot.}\, b}{\text{cot.}\, a - \text{cot.}\, b}$

14. $\dfrac{\text{coſ.}\,(a+b)}{\text{coſ.}\,(a \backsim b)} = \dfrac{\text{cot.}\, b - \text{tan.}\, a}{\text{cot.}\, b + \text{tan.}\, a} = \dfrac{\text{cot.}\, a - \text{tan.}\, b}{\text{cot.}\, a + \text{tan.}\, b}$

15. $\dfrac{\text{ſin.}\, a + \text{ſin.}\, b}{\text{ſin.}\, a - \text{ſin.}\, b} = \dfrac{\text{tan.}\,\frac{1}{2}(a+b)}{\text{tan.}\,\frac{1}{2}(a-b)}$

16. $\dfrac{\text{coſ.}\, a + \text{coſ.}\, b}{\text{coſ.}\, a \backsim \text{coſ.}\, b} = \dfrac{\text{cot.}\,\frac{1}{2}(a+b)}{\text{tan.}\,\frac{1}{2}(a-b)}$

17. $\text{ſin.}\,(a-b)\,\text{ſin.}\,(a+b) = \begin{cases} \text{ſin.}^2 a - \text{ſin.}^2 b, \text{ or} \\ \text{coſ.}^2 a \backsim \text{coſ.}^2 b \end{cases}$

18. $\text{coſ.}\,(a \backsim b)\,\text{coſ.}\,(a+b) = \text{coſ.}^2 a - \text{ſin.}^2 b$

19. $\dfrac{\text{ſin.}\,(a-b)\,\text{ſin.}\,(a+b)}{\text{coſ.}^2 a \,.\, \text{coſ.}^2 b} = \text{tan.}^2 a - \text{tan.}^2 b$

20. $\dfrac{\text{ſin.}\,(a-b)\,\text{ſin.}\,(a+b)}{\text{ſin.}^2 a \,.\, \text{ſin.}^2 b} = \text{cot.}^2 a - \text{cot.}^2 b$

If $a + b + c = 180°$, then

21. $\text{tan.}\, a \,.\, \text{tan.}\, b \,.\, \text{tan.}\, c = \text{tan.}\, a + \text{tan.}\, b + \text{tan.}\, c$

22. $\text{ſin.}\, a \,.\, \text{ſin.}\, b \,.\, \text{ſin.}\, c = \frac{1}{4}(\text{ſin.}\, 2a + \text{ſin.}\, 2b + \text{ſin.}\, 2c)$

It only remains now to exhibit the method of expreſſing the ſine, coſine, &c. of an arc, in terms of the arc itſelf; and reverſedly, to expreſs the arc in terms of its ſine, coſine, &c. This is performed with great facility, if we allow ourſelves to employ the principles of the doctrine of fluxions; but our object, in this place, is to perform the ſame by means of the *arithmetic of ſines* only.

For this purpoſe, let x repreſent any arc, then it is obvious that its ſine will be ſome function of this arc, and ſuch a function that it will change its ſign, without changing its magnitude, when the arc, without changing its magnitude changes its ſign, becauſe $\text{ſin.} -x = -\text{ſin.}\, x$; conſequently the developement of the ſine in functions of the arc, will contain only the odd powers of that arc; if, therefore, we repreſent the coefficients of the odd powers of x by A, B, C, &c. we ſhall have, or may aſſume,

$$\text{ſin.}\, x = \mathrm{A}x + \mathrm{B}x^3 + \mathrm{C}x^5 + \mathrm{D}x^7, \text{ \&c.} \qquad (\alpha)$$

And if z is another arc,

$$\text{ſin.}\, z = \mathrm{A}z + \mathrm{B}z^3 + \mathrm{C}z^5 + \mathrm{D}z^7 + \text{ \&c.}$$

by ſubtraction,

$$\text{ſin.}\, x - \text{ſin.}\, z = \mathrm{A}(x-z) + \mathrm{B}(x^3 - z^3) + \mathrm{C}(x^5 - z^5) + \text{ \&c.}$$

but $\text{ſin.}\, x - \text{ſin.}\, z = 2\,\text{ſin.}\,\frac{1}{2}(x-z) \,.\, \text{coſ.}\,\frac{1}{2}(x+z)$,

therefore $\dfrac{2\,\text{ſin.}\,\frac{1}{2}(x-z) \,.\, \text{coſ.}\,\frac{1}{2}(x+z)}{x-z} =$

$$\frac{\mathrm{A}(x-z) + \mathrm{B}(x^3-z^3) + \mathrm{C}(x^5-z^5)}{x-z} + \text{ \&c.}$$

Subſtituting now for $2\,\text{ſin.}\,\frac{1}{2}(x-z)$, its expanded value, by changing x, in the firſt ſeries, into $\frac{1}{2}(x-z)$, *viz.* $2\,\text{ſin.}\,\frac{1}{2}(x-z) = \mathrm{A}(x-z) + \frac{1}{4}\mathrm{B}(x-z)^3 + \frac{1}{16}\mathrm{C}(x-z)^5 + \text{ \&c.}$ and dividing both ſides by $(x-z)$, we have, by making, after the diviſion, $x = z$,

$$\mathrm{A}\,\text{coſ.}\, x = \mathrm{A} + 3\mathrm{B}x^2 + 5\mathrm{C}x^4 + 7\mathrm{D}x^6 + \text{ \&c.} \qquad (\beta)$$

and conſequently,

$$\mathrm{A}\,\text{coſ.}\, z = \mathrm{A} + 3\mathrm{B}z^2 + 5\mathrm{C}z^4 + 7\mathrm{D}z^6 + \text{ \&c.}$$

Whence, by ſubtraction, and obſerving that

$$\text{coſ.}\, x - \text{coſ.}\, z = -2\,\text{ſin.}\,\tfrac{1}{2}(x+z)\,\text{ſin.}\,\tfrac{1}{2}(x-z)$$

$$= -\text{ſin.}\,\tfrac{1}{2}(x+z)\left\{\mathrm{A}(x-z) + \mathrm{B}(x-z)^3 + \mathrm{C}(x-z)^5 + \text{ \&c.}\right\}$$

we ſhall have, after dividing both members by $x - z$, and then making $x = z$,

$$-\mathrm{A}^2\,\text{ſin.}\, x = 2\,.\,3\,\mathrm{B}x + 4\,.\,5\,\mathrm{C}x^3 + 6\,.\,7\,\mathrm{D}x^5 + \text{ \&c.}$$

But $\qquad \text{ſin.}\, x = \mathrm{A}x + \mathrm{B}x^3 + \mathrm{C}x^5 + \text{ \&c.}$

therefore

$$-\mathrm{A}^2\,\text{ſin.}\, x = -\mathrm{A}^3 x - \mathrm{A}^2\mathrm{B}x^3 - \mathrm{A}^2\mathrm{C}x^5 + \text{ \&c.}$$

Whence, by equating the coefficients of the homologous terms, we have

$$2\,.\,3\,\mathrm{B} = -\mathrm{A}^3;\ 4\,.\,5\,\mathrm{C} = -\mathrm{A}^2\mathrm{B};$$
$$6\,.\,7\,\mathrm{D} = -\mathrm{A}^2\mathrm{C}, \text{ \&c.}$$

$$\mathrm{B} = \frac{-\mathrm{A}^3}{2\,.\,3};\ \mathrm{C} = \frac{\mathrm{A}^5}{2\,.\,3\,.\,4\,.\,5};\ \mathrm{D} = -\frac{\mathrm{A}^7}{2\,.\,3\ldots7};\ \text{\&c.}$$

ſo that

$$\text{ſin.}\, x = \mathrm{A}x - \frac{\mathrm{A}^3x^3}{2\,.\,3} + \frac{\mathrm{A}^5x^5}{2\,.\,3\,.\,4\,.\,5} - \frac{\mathrm{A}^7x^7}{2\,.\,3\,.\,.\,7} + \text{ \&c.}$$

and it remains only to find the value of A; which is readily drawn from the following conſideration; *viz.* if we divide both ſides of this equation by x, it becomes

$$\frac{\text{ſin.}\, x}{x} = \mathrm{A} - \frac{\mathrm{A}^3x^2}{2\,.\,3} + \text{ \&c.}$$

which ought to anſwer to every value of x; but when x is indefinitely ſmall, $\text{ſin.}\, x = x$, and therefore the firſt number of the equation $= 1$; therefore the ſecond alſo equal 1, conſequently $\mathrm{A} = 1$; and we have therefore

$$\text{ſin.}\, x = x - \frac{x^3}{2\,.\,3} + \frac{x^5}{2\,.\,3\,.\,4\,.\,5} - \frac{x^7}{2\,.\,3\ldots7} + \text{ \&c.} \qquad \text{(XVII.)}$$

and by ſubſtituting, in equation (β), the above values of A, B, C, &c. we obtain

$$\text{coſ.}\, x = 1 - \frac{x^2}{2} + \frac{x^4}{2\,.\,3\,.\,4} - \frac{x^6}{2\,.\,3\ldots6} + \text{ \&c.} \qquad \text{(XVIII.)}$$

In order to expreſs the arc in terms of the ſine and coſine, let x and z be two arcs; let y be the ſine of the former, and u the ſine of the latter; and ſince, for the ſame reaſon as above, the expanded functions can contain only odd powers of y and u, we will ſuppoſe that

$$x = \mathrm{A}y + \mathrm{B}y^3 + \mathrm{C}y^5 + \mathrm{D}y^7 + \text{ \&c.} \qquad (\gamma)$$
$$z = \mathrm{A}u + \mathrm{B}u^3 + \mathrm{C}u^5 + \mathrm{D}u^7 + \text{ \&c.}$$

and, by ſubtraction, we have

$$x - z = A\,(y - u) + B\,(y^3 - n^3) + C\,(y^5 - u^5) + \text{\&c.}$$

Dividing here both ſides by $y - u$, and after the diviſion making $u = y$, it will become

$$\frac{x - z}{y - u} = A + 3\,By^2 + 5\,Cy^4 + 7\,Dy^6 + \text{\&c.} \qquad (\delta)$$

In order to eſtabliſh an identity, we muſt aſcertain what the firſt member becomes, on the ſuppoſition of $u = y$, after dividing by $y - u$. Now

$$\frac{x - z}{y - u} = \frac{x - z}{\text{ſin.}\,x - \text{ſin.}\,z} = \frac{x - z}{2\,\text{ſin.}\,\frac{1}{2}(x - z)\,\text{coſ.}\,\frac{1}{2}(x + z)}.$$

Subſtituting, in the latter denominator, for $2\,\text{ſin.}\,\frac{1}{2}(x - z)$, its value, as exhibited in No. (XVII.), and dividing both its members by $x - z$; that fraction becomes

$$\frac{1}{\left\{1 - \frac{1}{2 \cdot 3 \cdot 4}(x - z)^2 + \text{\&c.}\right\}\,\text{coſ.}\,\frac{1}{2}(x + z)};$$

and if now we make $x = z$, we ſhall find the reſult will be $= \frac{1}{\text{coſ.}\,x}$. Now

$$\frac{1}{\text{coſ.}\,x} = \frac{1}{\sqrt{(1 - \text{ſin.}^2 x)}} = \frac{1}{\sqrt{(1 - y^2)}} = (1 - y^2)^{-\frac{1}{2}}$$

$$= 1 + \frac{y^2}{2} + \frac{1 \cdot 3}{2 \cdot 4}y^4 + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}y^6 + \frac{1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6 \cdot 8}y^8 + \text{\&c.}$$

and conſequently this ſeries is identical with equation (δ), *viz.* with

$$A + 3\,By^2 + 5\,Cy^4 + 7\,Dy^6 + 9\,Ey^8 + \text{\&c.}$$

Comparing the homologous terms, we have

$$A = 1;\ B = \frac{1}{2 \cdot 3};\ C = \frac{1 \cdot 3}{2 \cdot 4 \cdot 5};\ D = \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7};\ \text{\&c.}$$

carrying, therefore, theſe values into the equation (γ), and ſubſtituting ſin. x for y, we have

$$x = \text{ſin.}\,x + \frac{\text{ſin.}^3 x}{2 \cdot 3} + \frac{1 \cdot 3\,\text{ſin.}^5 x}{2 \cdot 4 \cdot 5} + \frac{1 \cdot 3 \cdot 5\,\text{ſin.}^7 x}{2 \cdot 4 \cdot 6 \cdot 7} + \text{\&c.} \quad \text{(XIX.)}$$

and ſince the ſin. $x = \text{coſ.}\left(\frac{\pi}{2} - x\right)$, we have, by ſubſtituting this expreſſion for ſin. x, in the above ſeries,

$$x = \frac{\pi}{2} - \text{coſ.}\,x - \frac{\text{coſ.}^3 x}{2 \cdot 3} - \frac{1 \cdot 3\,\text{coſ.}^5 x}{2 \cdot 4 \cdot 5} - \frac{1 \cdot 3 \cdot 5\,\text{coſ.}^7 x}{2 \cdot 4 \cdot 6 \cdot 7}$$

$-$ &c. (XX.) in which the arc is expreſſed in terms of its coſine.

In order to inveſtigate a formula, which ſhall expreſs the arc in terms of its tangent, it may be ſhewn, as before, for the ſines, that only the odd powers of the tangent can enter into the expreſſions; aſſuming, therefore, x and z as two arcs, whoſe tangents are t and t', we may aſſume

$$x = At + Bt^3 + Ct^5 + \text{\&c.} \qquad (\varepsilon)$$
$$z = At' + Bt'^3 + Ct'^5 + \text{\&c.}$$

and, by ſubtraction, we ſhall have

$$x - z = A\,(t - t') + B\,(t^3 - t'^3) + C\,(t^5 - t'^5) + \text{\&c.}$$

Dividing both members by $t - t'$, and afterwards making $t = t'$, we have

$$\frac{x - z}{t - t'} = A + 3\,Bt^2 + 5\,Ct^4 + 7\,Dt^6 + \text{\&c.} \qquad (\theta)$$

Alſo, to eſtabliſh an identity, we have

$$\frac{x - z}{t - t'} = \frac{x - z}{\text{tan.}\,x - \text{tan.}\,z} = \frac{(x - z)\,\text{ſin.}\,(x - z)}{\text{coſ.}\,x\ .\ \text{coſ.}\,z}$$

$$= \frac{(x - z)\,\text{coſ.}\,x\ .\ \text{coſ.}\,z}{\text{ſin.}\,(x - z)}.$$

$$\text{But ſin.}\,(x - z) = (x - z) - \frac{1}{2 \cdot 3}(x - z)^3 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}(x - z)^5 - \text{\&c.}$$

If, therefore, we ſubſtitute this value for ſin. $(x - z)$, in the denominator of the latter fraction, it becomes, after dividing both members by $(x - z)$,

$$\frac{x - z}{t - t'} = \frac{\text{coſ.}\,x\ .\ \text{coſ.}\,z}{1 - \frac{x - z}{2 \cdot 3} + \frac{(x - z)^3}{2 \cdot 3 \cdot 4 \cdot 5} - \text{\&c.}}$$

which, on the ſuppoſition we have made of $t = t'$; and, conſequently, $x = z$, reduces to

$$\text{coſ.}^2 x = \frac{1}{\text{ſec.}^2 x} = \frac{1}{1 + \text{tan.}^2 x} = \frac{1}{1 + t^2} =$$
$$1 - t^2 + t^4 - t^6 + t^8 - \text{\&c.}$$

which is therefore identical with our equation (θ), *viz.*

$$A + 3\,Bt^2 + 5\,Ct^4 + 7\,Dt^6 + \text{\&c.}$$

whence, by comparing the co-efficients of the like powers of t, we have

$$A = 1,\ B = -\tfrac{1}{3},\ C = \tfrac{1}{5},\ D = -\tfrac{1}{7},\ \text{\&c.}$$

which values ſubſtituted in equation (ε), gives

$$x = \text{tan.}\,x - \tfrac{1}{3}\,\text{tan.}^3 x + \tfrac{1}{5}\,\text{tan.}^5 x - \tfrac{1}{7}\,\text{tan.}^7 x + \text{\&c.} \qquad \text{(XXI.)}$$

We ſhall now conclude this article by exhibiting, in a connected order, a few of the moſt important developements of angular functions; obſerving that A, B, C, &c. are the preceding terms.

$$1.\ a = \text{ſin.}\,a + \frac{\text{ſin.}^2 a}{2 \cdot 3}\,A + \frac{3^2\,\text{ſin.}^2 a}{4 \cdot 5}\,B + \frac{5^2\,\text{ſin.}^2 a}{6 \cdot 7}\,C + \frac{7^2\,\text{ſin.}^2 a}{8 \cdot 9}\,D + \text{\&c.}$$

where A, B, C, &c. are the preceding terms.

$$2.\ \text{ſin.}\,a = a - \frac{a^2}{2 \cdot 3}\,A + \frac{a^2}{4 \cdot 5}\,B - \frac{a^2}{6 \cdot 7}\,C + \frac{a^2}{8 \cdot 9}\,D - \text{\&c.}$$

$$3.\ a = 90^\circ - \text{coſ.}\,a - \frac{\text{coſ.}^3 a}{2 \cdot 3} - \frac{3\,\text{coſ.}^5 a}{2 \cdot 4 \cdot 5} - \frac{3 \cdot 5\,\text{coſ.}^7 a}{2 \cdot 4 \cdot 6 \cdot 7} - \text{\&c.}$$

$$4.\ \text{coſ.}\,a = 1 - \frac{a^2}{2}\,A - \frac{a^2}{3 \cdot 4}\,B - \frac{a^2}{5 \cdot 6}\,C - \frac{a^2}{7 \cdot 8}\,D - \text{\&c.}$$

$$5.\ a = \text{tan.}\,a - \frac{\text{tan.}^3 a}{3} + \frac{\text{tan.}^5 a}{5} - \frac{\text{tan.}^7 a}{7} + \text{\&c.}$$

$$6.\ \text{tan.}\ a = a + \frac{a^3}{3} + \frac{2a^5}{15} + \frac{17a^7}{315} + \frac{62a^9}{2835} + \text{\&c.}$$

$$7.\ a = \frac{1}{\text{cot.}\,a} - \frac{1}{3\,\text{cot.}^3 a} + \frac{1}{5\,\text{cot.}^5 a} - \frac{1}{7\,\text{cot.}^7 a} + \text{\&c.}$$

$$8.\ \text{cot.}\ a = \frac{1}{a} - \frac{a}{3} - \frac{a^3}{45} - \frac{2a^5}{945} - \frac{a^7}{4725} - \text{\&c.}$$

$$9.\ a = 90^\circ - \frac{1}{\text{ſec.}\,a} - \frac{1}{2 \cdot 3\,\text{ſec.}^3 a} - \frac{3}{2 \cdot 4 \cdot 5\,\text{ſec.}^5 a} - \text{\&c.}$$

$$10.\ \text{ſec.}\,a = \left\{\frac{\text{ſec.}\,a - 1}{\text{ſec.}\,a} + \frac{\text{ſec.}^3 a - 1}{2 \cdot 3\,\text{ſec.}^3 a} + \frac{3\,(\text{ſec.}^5 a - 1)}{2 \cdot 4 \cdot 5\,\text{ſec.}^5 a} + \frac{3 \cdot 5\,(\text{ſec.}^7 a - 1)}{2 \cdot 4 \cdot 6 \cdot 7\,\text{ſec.}^7 a},\ \text{\&c.}\right\}$$

$$11.\ a = \frac{1}{\text{coſec.}\,a} + \frac{1}{2 \cdot 3\,\text{coſec.}^3 a} + \frac{1 \cdot 3}{2 \cdot 4 \cdot 5\,\text{coſec.}^5 a} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7\,\text{coſec.}^7 a} + \text{\&c.}$$

$$12.\ \text{coſec.}\ a = \frac{1}{a} + \frac{a}{6} + \frac{7a^3}{360} + \frac{31a^5}{15120} + \frac{127a^7}{604800} + \text{\&c.}$$

$$13.\ a = 2\sqrt{2\,\text{verſ.}\,a}\left\{1 + \frac{\text{verſ.}\,a}{2^2 \cdot 3} + \frac{1 \cdot 3\,\text{verſ.}\,a}{2^3 \cdot 4 \cdot 5} + \frac{1 \cdot 3 \cdot 5\,\text{verſ.}\,a}{2^4 \cdot 4 \cdot 6 \cdot 7} + \text{\&c.}\right\}$$

$$14.\ \text{log. ſin.}\ a = \text{log.}\,a - \frac{1}{M}\left\{\frac{a^2}{2 \cdot 3} + \frac{a^4}{2^2 \cdot 3 \cdot 5} + \frac{a^6}{3^4 \cdot 5 \cdot 7} + \text{\&c.}\right\}$$

$$15.\ \text{log. coſ.}\ a = \text{log.}\,1 - \frac{1}{M}\left\{\frac{a^2}{2} + \frac{a^4}{3 \cdot 4} + \frac{a^6}{3^2 \cdot 5} + \text{\&c.}\right\}$$

$$16.\ \text{log. tan.}\ a = \text{log.}\,a + \frac{1}{M}\left\{\frac{a^2}{3} + \frac{7a^4}{2 \cdot 3^2 \cdot 5} + \frac{62a^6}{3^4 \cdot 5 \cdot 7} + \text{\&c.}\right\}$$

In all theſe ſeries, as alſo throughout the entire article, we have ſuppoſed radius = 1; if in any caſe the radius r be required, it may be introduced by giving it ſuch a power as will render the quantities on both ſides of the equation of the ſame dimenſion with regard to the powers of its factors.

Sines, *Coſines, &c. Figures of,* are figures made by conceiving the circumference of a circle extended out in a right line, upon every point of which are erected perpendicular ordinates, equal to the ſines, coſines, &c. of the correſponding arcs, and drawing a curve line through the extremities of all the ordinates, which is then the figure of the ſines, coſines, &c.

It appears that theſe figures took their riſe from the circumſtance of the extenſion of the meridian line by Edward Wright, who computed that line by collecting the ſucceſſive ſums of the ſecants, which is the ſame thing as the area of the figures of the ſecants. This being made up of all the ordinates or ſecants by the conſtruction of the figure, and in imitation of this, the figures of the other lines have been invented. By means of the figures of the ſecants, James Gregory ſhewed how the logarithmic tangents may be conſtructed in his "Exercitations Geometricæ," 4to. 1668.

Conſtruction of the Figures of the Sines, Coſines, &c.—Let A D B, &c. (*Plate* I. *fig.* 10.) be the circle, A D an arc, D E its ſine, C E its coſine, A E the verſed ſine, A F the tangent, G H the cotangent, C F the ſecant, and C H the coſecant.

Draw a line *aa* (*fig.* 11.), equal to the whole circumference A D G B A of the circle, upon which lay off alſo the length of ſeveral arcs, as of every ten degrees, from 0 at *a*, to 360° at the other end at *a*; upon theſe points raiſe perpendicular ordinates upwards or downwards, according as the ſine, coſine, &c. is affirmative or negative in that part of the circle; laſtly, upon theſe ſet off the length of the ſines, coſines, &c. correſponding to the arcs at thoſe points, or circumference *a a*, drawing a curve line through the extremities of all theſe ordinates, which will be the figure of the ſines, coſines, verſed ſines, tangents, cotangents, ſecants, and coſecants, as in *figs.* 11, 12, 13, 14, 15, 16, 17, where it may be obſerved, that the following curves are the ſame, namely, thoſe of the ſines and coſines, tangents and cotangents, and thoſe of the ſecants and coſecants, only ſome of their parts a little differently placed.

It may be known when any of theſe lines, *viz.* the ſines, coſines, &c. are poſitive or negative; that is, to be ſet upwards or downwards; by obſerving the following general rules for thoſe lines, in the 1ſt, 2d, 3d, and 4th quadrants of the circle.

The ſines	in the 1ſt and 2d	are	affirmative,
	in the 2d and 4th		negative.
The coſines	in the 1ſt and 4th		affirmative,
	in the 2d and 3d		negative.
The tangents	in the 1ſt and 3d		affirmative,
	in the 2d and 4th		negative.
The cotangents	in the 1ſt and 3d		affirmative,
	in the 2d and 4th		negative.
The ſecants	in the 1ſt and 4th		affirmative,
	in the 2d and 3d		negative.

and all the verſed ſines are affirmative.

To find the Equation and Area of each of thoſe Curves.—Draw an ordinate, *de*, putting r = the radius A C of the given circle, $x = ad$, or A D any abſciſs or arc, and $y = de$, its ordinate, which will be either the ſine D E = s, coſine C E = c, verſed ſine A E = v, tangent A F = t, cotangent G H = τ, ſecant C F = $ſ$, or coſecant C H = σ, according to the nature of the particular conſtruction. Now, from the nature of the circle are obtained theſe following general equations, expreſſing the relations between the fluxions and the circular arc, and its ſine, coſine, &c.

$$\dot{x} = \frac{r\dot{s}}{\sqrt{(r^2 - s^2)}} = \frac{-r\dot{c}}{\sqrt{(r^2 - c^2)}} = \frac{r\dot{v}}{\sqrt{(2rv - v^2)}}$$

$$= \frac{r^2\dot{t}}{r^2 + t^2} = \frac{-r^2\dot{\tau}}{r^2 + \tau^2} = \frac{r^2\dot{ſ}}{ſ\sqrt{(ſ - r^2)}} = \frac{-r^2\dot{\sigma}}{\sigma\sqrt{(\sigma^2 - r^2)}}$$

and theſe alſo expreſs the relation between the abſciſs and ordinates of the curves in queſtion, each in the order in which it ſtands; where x is the common abſciſs to all of them, and the reſpective ordinates are s, c, v, t, τ, $ſ$, and σ; and hence the area of any of theſe curves may be found as follows.

1. *In the Figure of the Sines*, (*fig.* 11.) Here $x = ad$, and s = the ordinate de, and the equation of the curve, as above, is $\dot{x} = \frac{r\dot{s}}{\sqrt{(r^2 - s^2)}}$. Hence the fluxion of the area, or $s\dot{x} = \frac{rs\dot{s}}{\sqrt{(r^2 - s^2)}}$, the correct fluent of which is $r^2 \mp r\sqrt{(r^2 - s^2)} = r^2 - rc = rv$ = the rectangle of radius and verſed ſine *minus* or *plus*, according as s is increaſing or decreaſing; which is a general expreſſion for the area ade in the figure of ſines. When $s = 0$, as at a, or b, this expreſſion becomes 0, or $2r^2$; that is, 0 at a, and $2r^2$ at b; that is, the whole area $acb = 2r^2$.

2. *In the Figure of the Coſines*, (*fig.* 12.) Here $x = ad$, and $c = de$; and the equation of the curve is $\dot{x} = \frac{-r\dot{c}}{\sqrt{(r^2 - c^2)}}$; hence the fluxion of the area $= c\dot{x} = \frac{-rc\dot{c}}{\sqrt{(r^2 - c^2)}}$; and the correct fluent of this $= r\sqrt{(r^2 - c^2)} = sr$, the rectangle of the radius and ſine for the general area $adec$. When $s = r$, or $c = 0$, this becomes r^2 = area afc, whoſe abſciſs af is equal to a quadrant of the circumference; the ſame as the figure of the ſines upon an equal abſciſs.

3. *In the Figure of the verſed Sines*, (*fig.* 13.) Here $x = ad$, and $v = de$, and the equation of the curve is $\dot{x} = \frac{r\dot{v}}{\sqrt{(2rv - v^2)}}$; hence the fluxion of the area is $v\dot{x} = \frac{rv\dot{v}}{\sqrt{(2rv - v^2)}} = \frac{r\dot{v}\sqrt{v}}{\sqrt{(2r - v)}}$; and the fluent of this is $rx - rs = r(x - s)$ = the general area in the figure of the verſed ſines. When ad is a quadrant, this becomes $\frac{3.1416}{2}r^2 - r^2$ = the area afg; and when ad is a ſemicircle it becomes $3.1416\,r^2$, the whole area of the figure of verſed ſines.

4. *In the Figure of the Tangents*, (*fig.* 14.) Here $x = ad$, and $t = de$; and the equation of the curve becomes $\dot{x} = \frac{r^2\dot{t}}{r^2 + t^2}$; and hence the fluxion of the area is $t\dot{x} = \frac{r^2t\dot{t}}{r^2 + t^2}$; the correct fluent of which is $\frac{1}{2}r^2$. hyp. log. $\frac{r^2 + t^2}{r^2} = r^2$. hyp. log. $\frac{\sqrt{(r^2 + t^2)}}{r} = r^2$. hyp. log. $\frac{ſ}{r}$; and hence the figure of the tangents may be uſed for the conſtruction of the logarithmic ſecants; a property firſt pointed out by Gregory at the end of his "Exercit. Geometricæ."

When ad becomes the quadrant af, t being then infinite, this becomes infinite for the area afg: and the ſame for the figure of cotangents, beginning at f, inſtead of a. See *fig.* 15.

5. *Figure of the Secants*, (*fig.* 16.) Here $x = ad$, and $ſ = de$; and the equation of the curves is $\dot{x} = \frac{r^2\dot{ſ}}{ſ\sqrt{(ſ^2 - r^2)}}$, and the fluxion of the area is $ſ\dot{x} = \frac{r^2ſ\dot{ſ}}{ſ\sqrt{(ſ^2 - r^2)}}$, the fluent of which is r^2 . hyp. log. $\frac{ſ + \sqrt{(ſ^2 - r^2)}}{r}$ for the general area ade; which is infinite when ad becomes equal to a quadrant. The ſame proceſs anſwers for the coſecants, beginning at f inſtead of a. See *fig.* 17.

Hence the meridional parts in Mercator's chart may be calculated for any latitude A D or ad. For the meridional parts : arc of latitude :: the ſum of the ſecants : the ſum of as many radii, or :: area ade : ad × rad. ac; or A D × A C in *fig.* 10.

Sines, *Line of*, a line on the ſector, Gunter's ſcale, &c. the deſcription and uſe of which ſee under the articles Sector, and Gunter's *Scale*.

In eſtimating the quantity of ſines, &c. we aſſume radius for unity; and determine the quantity of the ſines, tangents, and ſecants, in fractions thereof. From Ptolemy's Almageſt we learn, that the ancients divided the radius into 60 parts; which they called degrees, and thence determined the chords in minutes, ſeconds, and thirds; that is, in ſexageſimal fractions of the radius, which they likewiſe uſed in the reſolution of triangles.

The ſines, or half chords, for aught that appears, were firſt uſed by the Saracens.

Regiomontanus, at firſt, with the ancients, divided the radius into ſixty degrees, and determined the ſines of the ſeveral degrees in decimal fractions of it. But he afterwards found it would be more commodious to aſſume radius for 1; and thus introduced the preſent method into trigonometry.

In the common tables of ſines and tangents, the radius is conceived divided into 10000000 parts, beyond which we never go, in determining the quantity of the ſines and tangents. Hence, as the ſide of an hexagon ſubtends the ſixth part of a circle, and is equal to radius, the ſine of 30° is half the radius, or 5000000.

1. *The ſine* A D *being given* (*fig.* 4.), *to find the ſine-complement.* From the ſquare of the radius A C ſubtract the ſquare of the ſine A D; the remainder will be the ſquare of the ſine-complement D C or A G: whence the ſquare root being extracted, we have the ſine-complement. *E. gr.* Suppoſing A C 10000000, and A D 5000000, A G will be found 8660254, the ſine of 60°.

2. *The ſine* A D *of the arc* A E *being given* (*fig.* 18.), *to find the*

the ſine of the half arc, or half of A B. Find the chord of the arc A B; for half of this is its ſine. Thus ſuppoſing A G and A D, as in the preceding problem: we ſhall find the ſine of half the arc A B, or the ſine of 15°, = 2588190.

3. *The ſine* D G *of the arc* D F *being given, to find the ſine* D E *of the double arc* D B (*fig.* 19.) Since the angles at E and G are right angles, and the angle B is common to each triangle B C G and D E B, we ſhall have B C : C G :: B D : D E; wherefore C G being found by the firſt problem, and B D being double of D G, D E is found by the rule of proportion.

4. *The ſines* F G *and* D E (*fig.* 20.) *of the arcs* F A *and* D A, *whoſe difference* D F *is not greater than* 45 *minutes, being given, to find any intermediate ſine, as* I L. To the difference F D of the arcs, whoſe ſines are given, the difference of the arc A I, whoſe ſine is required, and A F, *viz.* I F, and the difference of the given ſines D H, find a fourth proportional: this, added to the leſs given ſine F G, the aggregate will be the ſine required.

5. *To find the ſine of* 45 *degrees.* Let H I (*fig.* 4.) be a quadrant of a circle; then will H C I be a right angle; conſequently the triangle rectangular; therefore $HI^2 = HC^2 + CI^2 = 2\,HC^2$; wherefore, ſince H C the whole ſine is 10000000; if from $2\,HC^2$, 200000000000000, be extracted the ſquare root 14142136; we ſhall have the chord H I, whoſe half 7071068, is the ſine of 45° required.

6. *The ſide of a pentagon being given* (ſee POLYGON), *the ſine of* 36° *may be eaſily found.* For the ſine of 36° is equal to half 11755706, *i. e.* = 5877853.

7. *The ſine of a minute, or* 60″, F G (*fig.* 20.) *being given, to find the ſine of one or more ſeconds* M N. Since the arcs A M and A F are very ſmall, A M F may be taken for a right line, without any ſenſible error in the decimal fractions of the radius, in which the ſine is expreſſed; that is, the arcs A M and A F may be taken proportional to their chords. Wherefore, ſince M N is parallel to F G, we ſhall have A F : F G :: A M : M N; therefore, A F, F G, and A M, being given, M N is eaſily had.

SINES, *to conſtruct a canon of.* The ſines of 30°, 15°, 45°, and 36° (which we have already ſhewn how to find) being had; we can thence conſtruct a canon of all the ſines to every minute, or every ſecond. For from the ſine of 36° we find thoſe of 18° 9° 4° 30′, and 2° 15′, by the ſecond problem: the ſines of 54° 72° 81° 85° 30′, and 87° 45′, &c. by the firſt problem.

Again, from the ſine of 45°, find the ſine of 22° 30′ 11° 15′, &c. From the ſine of 30°, and the ſine of 54°, find the ſine of 12°. From the ſine of 12°, find the ſines of 6° 3° 1° 30′ 45′ 78° 84°, &c. From the ſine of 15°, find the ſine of 7° 30′ 3° 45′, &c. till you have 120 ſines ſucceeding each other orderly, at an interval of 44 minutes. Between theſe, find the intermediate ſines by the fourth problem: thus will the canon be complete.

From the ſine of an arc given, to find the tangent and ſecant. See TANGENT, SECANT, and ſequel of this article.

To find the logarithm of a given ſine, called the *artificial* ſine, ſee LOGARITHM. Wolfii Element. Math. vol. i. p. 214, &c.

There are various other methods of conſtructing the triangular or trigonometrical canon. We ſhall here ſubjoin the following, as the moſt ſimple and eaſy. But it will be neceſſary to premiſe the three ſubſequent propoſitions.

1. *The ſine* E F *of an arc* A E (*fig.* 21.) *being given, to find its coſine* C F, *verſed ſine* A F, *tangent* A T, *cotangent* D H, *ſecant* C T, *and coſecant* C H. The coſine C F is evidently $= \sqrt{CE^2 - EF^2}$, and the verſed ſine = C E or C A − C F. And the triangles C F E, C A T, and C D H being ſimilar, we ſhall have C F : F E :: C A : AT; or the tangent will be a fourth proportional to the coſine, the ſine, and radius; and C F : C E (C A) :: C A : C T, whence the ſecant is a third proportional to the coſine and radius; and E F : C F :: C D : D H, or the cotangent is a fourth proportional to the ſine, coſine, and radius; and E F : E C (C D) :: C D : D H, or the coſecant, is a third proportional to the ſine and radius. Moreover, becauſe A T : A C :: C D (A C) : D H, the rectangle of the tangent and cotangent is equal to the ſquare of the radius, and, therefore, the tangent of half a right angle, being equal to its cotangent, is equal to the radius; and the cotangents of any two different arcs (repreſented by P and Q), are to one another inverſely as their tangents; for tang. P × cotang. P = rad.^2 = tang. Q × cotang. Q: therefore cotang. P : cotang. Q :: tang. Q : tang. P, or cotang. P : tang. Q :: cotang. Q : tang. P.

2. *If there be three equidifferent arcs* A B, A C, A D, (*fig.* 22.) *we ſhall have radius to the coſine of their common difference* B C, *or* C D, *as the ſine* C F *of the mean, to half the ſum of the ſines* B E + D G *of the two extremes; and as radius to the ſine of the common difference, ſo is the coſine of the mean to half the difference of the ſines of the two extremes.* For let B D be drawn, interſecting O C in *m*; alſo draw *m n* parallel to C F, and B H and *m v* parallel to A O. The arcs B C and C D being equal, O C is perpendicular to B D, and biſects it; and, therefore, B *m* or D *m* will be the ſine of B C or D C, and O *m* its coſine. Moreover *m n*, being an arithmetical mean between the ſines B E, D G, of the two extremes (becauſe B *m* = D *m*) is, therefore, equal to half their ſum, and D *v* equal to half their difference. But the triangles O C F, O *m n*, and D *v m*, being ſimilar, we ſhall have O C : O *m* :: C F : *m n*, and O C : D *m* :: F O : D *v*. Whence $mn\left(\frac{DG+BE}{2}\right) = \frac{Om \times CF}{OC}$, and $Dv\left(\frac{DG-BE}{2}\right) = \frac{Dm \times FO}{OC}$, and conſequently $DG + BE = \frac{2\,Om \times CF}{OC}$, and $DG - BE = \frac{2\,Dm \times FO}{OC}$. And, moreover, if the mean arc A C be 60°, O F its coſine will be = ſine 30° = $\frac{1}{2}$ chord 60° = $\frac{1}{2}$ O C; conſequently D G − B E will, in this caſe, be barely = D *m*, and D G = D *m* + B E. Hence it follows: 1. That if the ſine of the mean of three equidifferent arcs (radius being unity) be multiplied by twice the coſine of the common difference, and the ſine of either extreme be ſubtracted from the product, the remainder will be the ſine of the other extreme. And, 2. The ſine of any arc above 60° is equal to the ſine of another arc, as much below 60°, together with the ſine of its exceſs above 60°.

3. *To find the ſine of a very ſmall arc,* e. gr. *of* 15′. The chords of very ſmall arcs being to each other nearly as the arcs themſelves, we ſhall have $\frac{1}{384}$th of the ſemiperiphery : $\frac{1}{360}$th (:: 360 : 384) :: .00818121, the chord of $\frac{1}{384}$th : .008726624, the chord of $\frac{1}{360}$th of the ſemiperiphery, or half a degree, whoſe half, or .004363312, is the ſine of 15′, very nearly; and, therefore, 15′ : 1′ :: .004363312 : .000290888, the ſine of the arc of 1′ nearly.

Upon the foregoing principles the canon may be eaſily conſtructed. For, the ſine of 1′ being .0002908882, its ſquare is .00000008461594, which ſubtracted from the ſquare of the radius 1, leaves .99999991538406, whoſe ſquare root .9999999577 is the coſine of 1′, or the ſine of 89° 59′. Now having the ſine and coſine of 1′, the other ſines may be found in the following manner. Let the coſine of 1′ be called C, and we ſhall have by prop. 2. ſupra.

2 C × ſine 1′ — ſine 0′ = ſine 2′ = .0005817764
2 C × ſine 2′ — ſine 1′ = ſine 3′ = .0008726645
2 C × ſine 3′ — ſine 2′ = ſine 4′ = .0011635526
2 C × ſine 4′ — ſine 3′ = ſine 5′ = .0014544406
2 C × ſine 5′ — ſine 4′ = ſine 6′ = .0017453283, &c.

Thus are the ſines of 7′, 8′, 9′, &c. ſucceſſively derived from each other. The ſines of every degree and minute, up to 60°, being thus found; thoſe of above 60° will be had by addition only, by prop. 2. ſupra; and the ſines being all known, the tangents and ſecants will likewiſe become known by prop. 1. ſupra. If all theſe numbers be multiplied by the radius of any table (radius being here ſuppoſed unity), we ſhall have the natural ſines, tangents, &c. of ſuch a table. It will be ſufficient to compute the ſine of every fifth minute only by the preceding method; becauſe the ſines of all the intermediate arcs may be had from them, by taking the proportional parts of the differences ſo near, as to give the firſt ſix places true in each number. *Æ. gr.* 2 C 5′ × ſine 5′ — ſine 0′ = ſine 10′; ſubtract the ſine 5′ from that of 10′; add $\frac{1}{5}$th of the remainder to the ſine 5′, for the ſine of 6′, to which add the ſame $\frac{1}{5}$th for the ſine of 7′, &c. to 10′. Again, 2 C 5′ × ſine 10′ — ſine 5′ = ſine 15′, &c. Simpſon's Trigonometry, p. 10, &c. Robertſon's Elem. Navig. book iii. § 2.

The tables now chiefly uſed in trigonometrical computations, exhibit the logarithms of thoſe numbers, which expreſs the lengths of the ſines, tangents, &c. which, in order to diſtinguiſh them from the natural ones, are called logarithmic or artificial ſines, tangents, &c. A table of this kind, the uſe of which often occurs in the courſe of this work, is here annexed. The ſines, tangents, &c. of any arc are eaſily found, by ſeeking the degree at the top, if the arc be leſs than 45°, and the minutes at the ſide, beginning from the top, and by ſeeking the degree, &c. at the bottom, if the arc be greater than 45°. If a given logarithmic ſine, or tangent, falls between thoſe in the tables, the correſponding degrees and minutes may be reckoned $\frac{1}{4}$, $\frac{1}{3}$, or $\frac{1}{2}$, &c. minutes more than thoſe belonging to the neareſt leſs logarithm in the tables, according as its difference from the given one is $\frac{1}{4}$, or $\frac{1}{3}$, or $\frac{1}{2}$, &c. of the difference between the logarithm next greater and next leſs than the given log. Or generally, as 60″ is to the difference between any two conſecutive tabular ſines; ſo is the number of ſeconds beyond the leſs tabular ſine, to the proportional part that is to be added to it. Thus if it were required to find the ſine of 1° 28′ 45″:

Sine 1° 29′ is - - - - 8.4130676
Sine 1° 28′ is - - - - 8.4081614

Difference - - 49062

Then as 60″ : 49062 :: 45″ : 36796.

Therefore to - - - 8.4081614
Add - - - - 36796

Sine 1° 28′ 45″ is - - 8.4118410

And in the ſame manner may the tangent or cotangent of any angle be found to ſeconds. The ſecants and coſecants are not given in the table, but they are readily found as follows; *viz.* any coſecant is found by ſubtracting the ſine from 20.0000000, and the ſecant by ſubtracting the coſine from 20.0000000. See Sherwin's Mathematical Tables, which contain both the natural and artificial ſines, &c. and Gardiner's Tables of Logarithms, &c. in which the logarithms of the ſines are computed to every ſecond in the firſt ſeventy-two minutes of the quadrant. But the moſt correct Engliſh table at preſent extant is Dr. Hutton's, containing the logarithms of all numbers to 100000, and the natural and logarithmic ſines, coſines, tangents, &c. to every minute of the quadrant.

TABLE of Logarithmic Sines and Tangents to every Minute of the Quadrant.

Sine *of Incidence*, in *Catoptrics* and *Dioptrics*, is uſed for the ſine of the angle of incidence.

Sine *of Reflection*, in *Catoptrics*, is uſed for the ſine of the angle of reflection.

Sine *of Refraction*, in *Dioptrics*, is uſed for the ſine of the angle of refraction.

Sine *aſſenſu capituli*, in *Law*, a writ that lies where a biſhop, dean, prebendary, or maſter of an hoſpital, aliens the lands holden in right of his biſhopric, deanery, houſe, &c. without the aſſent of the chapter or fraternity; in which caſe his ſucceſſor ſhall have this writ.

SINE-CURES, are eccleſiaſtical benefices, without cure of ſouls. Their original was as follows: The rector (with proper conſent) had a power to intitle a vicar in his church to officiate under him; and this was often done: and by this means, two perſons were inſtituted to the ſame church and both to the cure of ſouls, and both did actually officiate. So that however the rectors of ſine-cures, by having been long excuſed from reſidence, are in common opinion diſcharged from the cure of ſouls, (which is the reaſon of the name,) and however the cure is ſaid in the law-books to be in them *habitualiter* only; yet in ſtrictneſs, and with regard to their original inſtitution, the cure is in them *actualiter*, as much as it is in the vicar. Gibſ. 719. Johnſ. 85.

That is to ſay, where they come in by inſtitution; but if the rectory is a donative, the caſe is otherwiſe: for then coming in by donation, they have not the cure of ſouls committed to them. And theſe are moſt properly ſine-cures, according to the genuine ſignification of the word. Johnſ. 85.

No church where there is but one incumbent can properly be a ſine-cure: and though the church being down, or the pariſh being become deſtitute of pariſhioners, the incumbent may be thereby neceſſarily acquitted from the actual performance of public duty, yet he is ſtill under an obligation to do it, whenever a church ſhall be built, and there is a competent number of inhabitants; and, in the mean while, if the church be preſentative, as moſt of ſuch churches are, the incumbent is inſtituted into the cure of ſouls. Such benefices are rather depopulations than ſine-cures; and it will be proper for the new incumbent to read the thirty-nine articles, and the liturgy, in the church-yard, &c. and to do whatever other incumbents uſually do.

But a rectory, or portion of it, may properly be a ſine-cure, if there be a vicar under the rector, endowed and charged with the cure; in which caſe it does not come within the ſtatute of pluralities, 21 Hen. VIII. c. 13.

Here, therefore, no diſpenſation is neceſſary to hold the ſine-cure with a former living; nor need the incumbent read the articles, or divine ſervice, as required by 13 Eliz. c. 12. which extends only to a benefice with cure.

A ſine-cure donative wants no inſtitution and induction, but one preſentative muſt have both, eſpecially if it conſiſt in glebe and tithes, and not in a portion of money; but the inſtitution muſt not run *in curam animarum*, but *in rectoriam, ſive portionem rectoriæ de* A. B. &c.

By the above-mentioned ſtatute (21 Hen. VIII.) not only prebends, and rectories with vicarages endowed, but deaneries and archdeaconries are declared to be benefices *without cure.*

SINE DIE, in *Law*. When judgment is given againſt the plaintiff, he is ſaid to be *in miſericordia pro falſo clamore ſuo*; and for the defendant, it is ſaid, *eat inde ſine die*; i. e. he is diſmiſſed the court.

The phraſe is alſo uſed in parliament, for the adjournment of any debate, without fixing the day when it ſhall come on again; which is looked upon as a genteeler diſmiſſion of the thing in queſtion.

SINEER, in *Geography*, a town of Hindooſtan, in Baglana; 3 miles W. of Junere.

SINEGAR CREEK, a river of Maryland, which runs into the Potomack, N. lat. 39° 8′. W. long. 77° 33′.

SINEMAHONING, a north-weſt branch of the river Suſquehanna.

SINE PARI, in *Anatomy*, an epithet applied to the vena azygos, which latter is an equivalent expreſſion derived from the Greek. It means the *ſingle* vein; as there is only one in the body, and not a pair, as in general, conſiſting of a right and left veſſel. See VEIN.

SINEPUXENT INLET, in *Geography*, a bay on the S.E. coaſt of Maryland. N. lat. 38° 20′.

SINERVAS, in *Ancient Geography*, a town of the Leſſer Armenia, on the route from Satala to Melitene, between Carſagis and Analiba. It. of Anton.

SINES, in *Geography*, a ſea-port town of Portugal, in Eſtremadura, containing about 1400 inhabitants; 39 miles S. of Setuval. N. lat. 37° 46′. W. long. 8° 51′.

SINESCLA, a town of Aſiatic Turkey, in the province of Diarbekir; 80 miles E. of Rabba.

SINEU, a town of the iſland of Majorca; 20 miles E. of Parma.

SINEW properly denotes what we call a *nerve;* though, in common ſpeech, it is rather uſed for a *tendon*.

The Hebrews do not eat the ſinew of the thighs of animals, in memory of the ſinew of Jacob's thigh, which the angel touched. This abſtinence is not commanded by the law, and ſome interpreters think that it is an act of voluntary devotion.

SINEW, in the *Manege*. To unſinew a horſe, called in French *enerver*, is to cut the two tendons on the ſide of the head, about five inches under the eyes; which two join in one at the tip, or the end of the noſe, in order to perform its motion. This tendon at the tip of the noſe is likewiſe cut. We unſinew, in order to dry the head, and make it ſmaller.

SINEW-*Shrunk*, is ſaid of a horſe that is over-rid, and ſo worn down with fatigue, that he becomes gaunt-bellied, through a ſtiffneſs and contraction of the two ſinews that are under his belly.

SINEW-*Sprung*, is a violent attaint, or over-reach, in which a horſe ſtrikes the toe of his hinder feet againſt the ſinew of the fore-legs.

SINF, in the *Materia Medica of the Ancients*, a word uſed to expreſs the ſame as *agallochum*, or lignum aloes.

SIN-FONG, in *Geography*, a town of China, of the third rank, in Kiang-ſi; 27 miles S. of Kan-cheou.

SING, a town of Dalmatia, built by the Turks, in oppoſition to Cliſſa. It was ſtrongly fortified; and the Venetians, after taking this place in the year 1686, ſtrengthened its fortifications, in order to ſecure it to themſelves; 16 miles N. of Spalatro.—Alſo, a town of Corea; 153 miles S.S.E. of King-ki-tao. N. lat. 35° 27′. E. long. 127° 49′.—Alſo, a town of Corea; 25 miles S.E. of Long-Kouang.

SINGA, in *Ancient Geography*, a town of Syria, in the Comagene. Ptolemy.

SIN-GAN, in *Geography*, a city of China, of the firſt rank, and capital of the province of Chen-ſi; next to Peking, one of the largeſt and moſt beautiful cities in the kingdom. Its walls are thick, very high, and four leagues in circumference; they are flanked with a great number of towers, and ſurrounded by a deep ditch. Some of its gates are magnificent and remarkably lofty. In this city is ſtill ſeen a palace where the ancient kings of Chen-ſi reſided, the extent of whoſe country, and the bravery of their people, once rendered them formidable to their neighbours. The houſes are, according to the Chineſe faſhion, low and ill-conſtructed; and the furniture, on account of the ſcarcity of good artiſts, inferior to that in the ſouthern provinces; porcelain being very rare, and the varniſh coarſe. The inhabitants are generally more robuſt, and brave, and better formed for enduring fatigue, and alſo of greater ſtature, than thoſe of the other provinces. The principal Tartar forces deſtined for the defence of the northern part of the empire are garriſoned in this city, under a general of their own nation, who, with his ſoldiers, occupies a quarter of the city, ſeparated from the reſt by a wall. Bats of a ſingular ſpecies are found in the territories of Sin-gan; they are as large as domeſtic fowls, and the Chineſe prefer their fleſh to that of the moſt delicate chickens. This country alſo furniſhes the ladies with a white paint, which they uſe for embelliſhing their complexions. It appears, by an inſcription on a marble monument dug up here in 1625, that the Chriſtian religion flouriſhed in China from the year 636 to 782. This capital has 37 cities under its juriſdiction; ſix of the ſecond claſs and 31 of the third. The Mandarins, who are numerous in this city, are moſtly Tartars. N. lat. 35° 14′. E. long. 108° 29′. Groſier.—Alſo, a town of China, of the third rank, in Pe-tche-li; 22 miles E.N.E. of Pao-ting.

SINGANA, in *Botany*, Aubl. Guian. 574. Juſſ. 257, altered by Aublet from the name *Singan Singa*, given by the blacks in Guiana to the fruit of this ſhrub. See STERBECKIA.

SINGANELLORE, in *Geography*, a town of Hindooſtan, in Coimbetore; 5 miles E. of Coimbetore.

SINGAPETTY, a town of Hindooſtan; 17 miles S.S.W. of Tinevelly.

SINGARA, SINJER, in *Ancient Geography*, an important town of Aſia, in Meſopotamia, on the banks of the river Mygdonius. Dion Caſſius ſays that it was taken by Trajan; and that it afterwards became a Roman colony, under the appellations of Aurelia and Septimia, which it bears on medals.

SINGARPETTY, in *Geography*, a town of Hindooſtan, in Barramaul; 25 miles E.N.E. of Darempoury.

SINGARPILLY, a town of Hindooſtan, in Myſore; 23 miles E.S.E. of Chinna Balabaram.

SINGAS, SINSJA, in *Ancient Geography*, a river of Aſia, which, according to Ptolemy, flowed from Pieria, the moſt northerly canton of Syria, and diſcharged itſelf into the Euphrates S.E. of Samoſata, between Arudis and Porſica.

SINGBOON, in *Geography*, a circar of Hindooſtan, of ſmall extent, bounded N.E. and E. by Bengal, S. by Mohurbunge, W. and N.W. by Bahar.

SINGEAH, a town of Hindooſtan, in Bahar; 10 miles N. of Hajypour. N. lat. 25° 52′. E. long. 85° 24′.

SINGECOLLAM, a town of Hindooſtan; 10 miles S. of Tinevelly.

SINGECONDA, a town of Hindooſtan, in the Carnatic; 25 miles N. of Ongole.

SINGEE, a town of Hindooſtan, in Bahar; 24 miles S.S.E. of Durbungah. N. lat. 25° 45′. E. long. 86° 21′.

SINGERAM, a town of Hindooſtan, in Golconda; 15 miles S.E. of Hydrabad.

SINGERBILL, a town of Hindooſtan, in Bengal; 30 miles N. of Cormillah.

SINGERS, in the *Jewiſh Antiquities*. See CHANTOR.

SINGERS in Lulli's operas. See LULLI.

SINGESECKEN, in *Geography*, a town of Norway, in the province of Drontheim; 46 miles S.S.W. of Drontheim.

SINGFING, a town of America, in New York, on the river Hudſon; 27 miles N. of New York. N. lat. 41° 8'. W. long. 73° 53'.

SINGHOLE, a town of Hindooſtan, in Gurry Mundella; 36 miles N.N.W. of Gurrah.

SINGHORE, a town of Hindooſtan, in Oude; 16 miles S.E. of Manickpour.

SINGHYA, a town of Hindooſtan, in Bahar; 10 miles N. of Hajypour.

SINGILIEV, a town of Ruſſia, in the government of Simbirſk, on the Volga; 24 miles S. of Simbirſk. N. lat. 54° 1'. E. long. 48° 34'.

SINGING, the act of making divers inflexions of the voice, agreeable to the ear, and correſponding to the notes of a ſong, or piece of melody.

The Greek muſicians, ſays Dr. Smith in his Harmonics, p. 3. note *c*, rightly deſcribe the difference between the manner of ſinging and that of talking. They conſidered two motions in the voice; the one continued, and uſed in talking; the other diſcrete, and uſed in ſinging. In the continued motion, the voice never reſts at any certain pitch, but waves up and down by inſenſible degrees; and in the diſcrete motion it does the contrary, frequently reſting or ſtaying at certain places, and leaping from one to another by ſenſible intervals. Euclid's Introductio Harmonica, p. 2. In the former caſe, the vibrations of the air are continually accelerated and retarded by turns, and by very ſmall degrees, and in the latter by large ones.

The firſt thing done, in learning to ſing, is to raiſe a ſcale of notes, by tones and ſemitones, to an octave; and deſcend again by the ſame notes; and then to riſe and fall by greater intervals, as a 3d, 4th, and 5th, and to do all this by notes of different pitch.

Then theſe notes are repreſented by lines and ſpaces, to which the ſyllables *fa, ſol, la, mi,* are applied, and the pupil is taught to name each line and ſpace by them; whence this practice is uſually called *ſol-fa-ing*. The nature, reaſon, defects, &c. of which, ſee under the article SOL-FA-ING.

For the hiſtory of ſinging, as a part of religious worſhip, ſee *Choral* SERVICE.

SINGING, *Proceſſional*. It was about the year 386, during the perſecution of the orthodox Chriſtians by the empreſs Juſtina, mother to the then young emperor Valentinian II. that eccleſiaſtical muſic was introduced in favour of the Arians. "At this time," ſays St. Auguſtine, "it was firſt ordered that hymns and pſalms ſhould be ſung after the manner of eaſtern nations, that the people might not languiſh and pine away with a tedious ſorrow, and from that time to the preſent it is retained at Milan, and imitated by almoſt all the other congregations of the world."

Muſic is ſaid by ſome of the fathers to have drawn the Gentiles frequently into the church through mere curioſity; who liked its ceremonies ſo well, that they were baptized before their departure. The generality of our parochial muſic is not likely to produce ſimilar effects; being ſuch as would ſooner drive Chriſtians with good ears *out* of the church, than draw Pagans *into it*.

About this time, during the contention between the orthodox Chriſtians and the Arians, we find by Socrates the hiſtorian, (l. vi. c. 8.) that the heretics uſed to ſing hymns, marching through the ſtreets of Conſtantinople in proceſſion, with which the vulgar were ſo much captivated, that the orthodox, under the direction of St. Chryſoſtom, thought it neceſſary to follow the example which had been ſet them by their greateſt enemies. Proceſſional ſinging had been long practiſed by the Pagans, but no mention is made of it among Chriſtians before this period.

SINGING *in the Church by the primitive Chriſtians*. With reſpect to the muſic that was firſt uſed by the Chriſtians, or eſtabliſhed in the church by the firſt emperors that were converted, as no ſpecimens remain, it is difficult to determine of what kind it was. That ſome part of the ſacred muſic of the apoſtles and their immediate ſucceſſors, in Paleſtine and the adjacent countries, may have been ſuch as was uſed by the Hebrews, particularly in chanting the pſalms, is probable; but it is no leſs probable that the muſic of the hymns which were firſt received in the church, wherever Paganiſm had prevailed, reſembled that which had been many ages uſed in the temple-worſhip of the Greeks and Romans. Of this, the verſification of thoſe hymns affords an indiſputable proof, as it by no means reſembles that of the pſalms, or of any other Hebrew poetry. And examples may be found in all the breviaries, miſſals, and antiphonaries, ancient and modern, of every ſpecies of verſification which has been practiſed by the Greek and Roman poets, particularly the lyric; ſuch as the Alcmanian, Alcaic, Sapphic, &c.

St. Hilary, biſhop of Poictiers, and St. Ambroſe, are ſaid to have been the firſt that compoſed hymns to be ſung in the weſtern churches. Both theſe fathers flouriſhed about the middle of the fourth century; but Prudentius, a Chriſtian poet, contemporary with Theodoſius, who died in 395, was author of moſt of the hymns in the Roman breviary.

SINGING, *Celeſtial*. It ſeems as if the primitive Chriſtians had had no conceptions more ſublime of the employment of the bleſt in the celeſtial abode, than that they were eternally ſinging. The ancient hymn, "Te Deum laudamus," ſtill retained in the church, appears to have furniſhed the poet Dante with a model of the 28th canto of his "Paradiſo," where, under three different hierarchies, conſiſting each of three choirs or choruſes, the heavenly hoſt of cherubim and ſeraphim are ſinging perpetual hoſannahs. Milton has aſſigned them the ſame employment:

> ——— Their golden harps they took:
> Harps ever tun'd, that glittering by their ſide
> Like quivers hung, and with preamble ſweet
> Of charming ſymphony they introduce
> Their ſacred ſong, and waken raptures high;
> No voice exempt, no voice but well could join
> Melodious part, ſuch concord is in heaven.
>
> Parad. Loſt, book iii.

Orazio Benivoli compoſed, in the laſt century, a maſs for the ceſſation of the plague at Rome, upon the ſame idea, for ſix choirs, of four parts each, the ſcore conſiſting of twenty-four different parts: it was performed in St. Peter's church, of which he was maeſtro di capella, and the ſingers, amounting to more than two hundred, were arranged in different circles of the dome; the ſixth choir occupying the ſummit of the cupola.

SINGING *in England by Madrigaliſts*. Choral compoſitions, madrigals, and ſongs in that ſtyle, always of many parts, being the only vocal muſic that was in favour with maſters and their moſt powerful patrons, precluded all refinement in the performance: as fugues, canons, and full choruſes, of which they chiefly conſiſted, are founded upon democratic principles, which admit of no ſovereignty; and whatever good they contain, is equally diſtributed to all ranks in the muſical ſtate; the art of ſinging, therefore, in theſe times, further than was neceſſary to keep a performer in tune and time, muſt have been unknown: the poſſeſſor of the moſt exquiſite voice had no more frequent opportunities allowed of diſplaying it, than the moſt diſagreeable; ſolo ſongs, anthems, and cantatas, being productions of later times. The penalty for the crime of playing a ſolo at the concert of ancient muſic was five guineas; but at this time, if inſtead of that ſum being forfeited, five hundred had been offered to the individual who could perform ſuch a feat, fewer candidates would have entered the liſts than if the like premium had been offered for flying from Saliſbury ſteeple over Old Sarum, without a balloon.

Singing, *Parochial*. See Psalmody. See alſo Sternhold and Hopkins.

Singing *in Italy*, during the 16th century. Zacconi, one of the beſt Italian writers on muſic of that period, in his "Prattica di Muſica," publiſhed 1596, chiefly dwells, in the firſt book, on the ſuperiority of the ſinging and ſingers of his own time, over all that preceded them; and has a long chapter upon the manner of gracing and embelliſhing a melody, where he tells us, "Che ſtile ſi tenghi nel far di *gorgia;* dell' uſo de i moderni *paſſagi*, come ſi *fioriſchino* le cantilene;" and ſpeaks of *acconciature*, as the modern Italians do of *riffioramenti*, or graces. The diviſions, however, into which he breaks paſſages, in order to *embelliſh* them, if adopted by an opera-ſinger of the preſent times, would be like a modern fine lady appearing at court in the furbelows and flounces of queen Elizabeth, or a fine gentleman in the peruke of ſir Cloudeſley Shovel.

Singing *in France*, during the 17th century. See Merſennus, and St. Evremond.

Singing *in England*, previous to the reign of queen Anne.

Muſic at all times has been called in to the aſſiſtance of weak plays and unattractive actors in our national theatres; and incidental ſongs, and ſinging between the acts, have been found ſo alluring, that when there was no plan formed for exhibiting muſical dramas, ſingers have been engaged at conſiderable ſalaries, expreſsly for that purpoſe.

Before the laſt century, the art of ſinging, indeed, ſeems to have been little cultivated among us, by either ſex, beyond what concerned time and tune. The honourable Roger North, in his manuſcript "Memoirs of Muſic," ſpeaks of the younger Baniſter as an excellent ſinging-maſter; but the players, who ſung Purcell's ſongs on the ſtage, ſeem to have had nothing but voice and action to recommend them: ſuch as Bowen, Harris, Freeman, and Pate, among the men; and among the women, Mrs. Davies, Miſs Shore, afterwards wife to Colley Cibber, Mrs. Croſs, Miſs Champion, and Mrs. Bracegirdle. It was, however, a powerful recommendation to a ſong, during the 17th century, to ſay that it had been performed at the playhouſe. How different from modern times! Church muſic, by the gay and faſtidious frequenters of the opera, before, as well as after it had been heard, is pronounced to be *old-faſhioned*, and playhouſe muſic *vulgar*. Till the reign of queen Anne, indeed, the gentlemen of the chapel royal were occaſionally allowed to ſing on the ſtage; but that princeſs thinking the practice indecent, prohibited its continuance. There are few inſtances of vocal performers, eſpecially female, being brought on our ſtage, but by accident. The fear of ſeduction, profligacy, and the world's opinion, deters parents from educating their children with a view to a profeſſion, which nothing but uncommon ſucceſs and prudence can render honourable in the eyes of the moſt ſerious part of the nation. The generality of female ſingers, therefore, having every thing to learn after leiſure for ſtudy is no longer in their power, uſually remain ignorant of the principles of their art, and ſo totally dependent on a maſter, as to be obliged to perpetuate that apprenticeſhip, which ought to have been ſerved before they ſet up for themſelves.

In 1763, the paſticcio burletta of "Love in a Village," and in 1765 "The Summer's Tale," and "The Maid of the Mill," betrayed us into a taſte for Italian melody, which has been the model of moſt of our vocal compoſers in and out of the theatre ever ſince. The "Duenna," another favourite Engliſh paſticcio, in 1775, helped us on, and Dr. Arnold, Mr. Dibdin, and Mr. Shield, have very judiciouſly complied with the reigning taſte, and imitated or adopted the opera ſtyle in all its viciſſitudes. Linley of Bath, and Jackſon of Exeter, in their elegies at leaſt, have ſtedfaſtly adhered to a ſtyle of their own, which ſeems to have been formed upon the melodies of our beſt old Engliſh maſters, and thoſe of the laſt age, that were moſt worthy of being preſerved.

Till the Italian opera was eſtabliſhed in this country, little was expected of a ſinger beſides voice and an ear. Indeed, long after that period, good taſte in ſinging was ſo little diffuſed throughout the iſland, that the great and exquiſite performers who came hither from the continent ſeem to have made but a ſmall impreſſion on their aſtoniſhed hearers. Nicolini, Seneſino, Bernacchi, Fauſtina, Cuzzoni, Farinelli, Caſſarelli, Careſtini, Conti, Monticelli, Mingotti, Elizi, Manzoli, Guarducci, and Guadagni, had no effect upon our national taſte; and though a few individuals among the people of faſhion, by private inſtructions from them, and by the beſt of all leſſons, hearing them frequently perform in public, diminiſhed the original ſin of our native *brogue* and vulgar expreſſion; yet as theſe pupils could be heard but by few, their power was local, and no more likely to have any general effect upon our national cantilena, than their learning French and Italian upon our general language. It is not difficult, however, to fix the era of a change in our vocal muſic, which ſeems to have remained ſtationary for near half a century. It was begun by the compoſitions and inſtructions of Dr. Arne, who endeavoured to refine our melody and ſinging, more from Italian than Engliſh models; and was greatly accelerated by the paſticcio Engliſh operas above mentioned, as well as by the inſtructions of Tedeſchini, Cocchi, Vento, and Giardini, who were employed about this time to teach ſeveral of our playhouſe ſingers. Tenducci's performance in Artaxerxes had a rapid effect upon the public taſte, and ſtimulated to imitation all that were poſſeſſed of good ears and flexible voices. In later times, the ſcholars of Sacchini, Piozzi, Parſons, and others, with the public concerts, where the beſt compoſitions and moſt exquiſite performances of all kinds were conſtantly heard, completed the revolution; and it may be with truth and certainty affirmed, that our taſte and judgment in both, even at the playhouſes, differ as much from thoſe of twenty or thirty years ago, as the manners of a civilized people from thoſe of ſavages.

Singing *of Birds*. See Song *of Birds*.

SINGINGING, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the E. coaſt of the iſland of Naſſau. S. lat. 3° 50′. E. long. 100° 2′.

SINGITICUS Sinus, in *Ancient Geography*, a gulf of Macedonia, in the Ægean ſea.

SINGIVENDA, in *Geography*, a town of Hindooſtan, in the Carnatic; 28 miles N.N.W. of Ongole.

SINGLE, among *Sportſmen*, the tail of any of the deer kind.

Single *Bond* or *Obligation*, *ſimplex obligatio*, in *Law*, is a deed, by which the obligor obliges himſelf, his heirs, executors, and adminiſtrators, to pay a certain ſum of money to another at a day appointed. See Obligation.

Single *Caſt*, in *Huſbandry*, a term uſed by farmers for that ſort of ſowing, that diſperſes the neceſſary quantity of corn at one bout.

SINGLE *Echo, Fine, Poſition, Propoſition, Rafters, Tenaille,* and *Voucher.* See the ſubſtantives.

SINGLE-*Horſe Carts,* in *Agriculture.* See CART.

SINGLES. See PETTY *Singles.*

SINGO, in *Geography,* a town of European Turkey, in the province of Macedonia, near mount Athos.

SINGON, an iſland near the coaſt of Sweden, at the entrance into the gulf of Finland. N. lat. 60° 11′. E. long. 18° 20′.

SINGOONMAW, a town of the Birman empire; 16 miles S. of Pegongmew.

SINGOR, a ſea-port town of Aſia, in the kingdom of Siam, on the coaſt of Malacca. N. lat. 6° 40′. E. long. 101° 14′.

SINGPINE, a town of Bengal; 25 miles S.E. of Nattore.

SINGPOUR, a town of Bengal; 22 miles E.S.E. of Ramgur.—Alſo, a town of Bengal; 8 miles S.E. of Koonda.—Alſo, a town of Hindooſtan, in the circar of Sohajepour; 8 miles S. of Sohajepour.

SINGRAMOW, a town of Hindooſtan, in Oude; 24 miles S.S.E. of Sultanpour.

SINGRECOTTA, a town of Hindooſtan, in the circar of Cicacole; 23 miles W. of Vizianagram.

SINGREMON, a town of Hindooſtan, in Allahabad; 23 miles N.N.E. of Gazypour.

SINGREPETTA, a town of Hindooſtan, in the Carnatic; 15 miles S.E. of Tritchinopoly.

SINGROWLA, a town of Hindooſtan, in Allahabad, S.W. of Bahar.

SING-SING, a town of America, in the ſtate of New York; 35 miles N. of New York.

SINGUAR, a town of Hindooſtan, in Bahar; 14 miles E.N.E. of Hajypour.

SINGUE, a town of Hindooſtan, in Bahar; 38 miles S. of Bahar.

SINGULAR NUMBER, in *Grammar,* the firſt manner of declining nouns, and conjugating verbs; uſed when we only ſpeak of a ſingle perſon or thing. See NUMBER.

SINGULAR *Hiſtory.* See HISTORY.

SINGULAR *Propoſition.* See PROPOSITION.

SINGULARIS, or SINGLE, in the *Manege,* a name given by the Romans to a horſe, upon which a man rode, in their races, without a ſaddle, uſing only a cloth, like the Greeks, faſtened with a ſurcingle, or elſe ſitting upon the bare back.

SINGULATOR, among the Romans, a horſeman who rode with one horſe only.

SINGULTUS, in *Medicine,* a ſpaſmodic affection of the diaphragm, which, from the ſound which accompanies it, is commonly called *hickup;* under which head ſee an ample account of this affection.

SINGUM, in *Geography,* a town of Hindooſtan, in the Carnatic; 23 miles S.S.W. of Tritchinopoly.

SINGUR, a town of Hindooſtan, in Bahar; 35 miles S.E. of Gayhah.—Alſo, a town of Hindooſtan, in Viſiapour; 12 miles S. of Poonah.

SINGUS, in *Ancient Geography,* a town of Macedonia, in Chalcidis, on the Singitic gulf. Ptol.

SING-Y, in *Geography,* a town of China, of the third rank, in Quang-tong; 17 miles N. of Kao-tcheou.

SINHALA, in *Ancient Geography,* a name formerly given to the iſland of Ceylon, formed from the Sanſcrit Sinha, a lion, and given to it on account of its being inhabited by Sinhalas, or the offspring of a lion. See Aſiatic Reſearches, vol. i. p. 48.

SIN-HIANG, in *Geography,* a town of China, of the third rank, in Ho-nan, on the river Ki; 12 miles S.W. of Oue-kiun.

SIN-HING, a ſmall iſland near the coaſt of China, in the Eaſtern ſea; 3 miles S. of Tſong-ming. N. lat. 31° 32′. E. long. 121°.—Alſo, a town of China, of the third rank, in Quang-tong; 27 miles S. of Tchao-king.—Alſo, a city of China, of the ſecond rank, in Yun-nan. N. lat. 24° 30′. E. long. 102° 23′.

SIN-HO, a town of China, of the third rank, in Petche-li; 15 miles S.W. of Khi.

SIN-HOA, a ſea-port town of Cochinchina. N. lat. 17°. E. long. 88° 14′.—Alſo, a town of China, of the third rank, in Hou-quang, on the river Lo; 32 miles N.N.W. of Pao-king.

SIN-HOEI, a town of China, of the third rank, in Quang-tong; 40 miles N.W. of Macao.—Alſo, a town of China, of the third rank, in Quang-tong; 45 miles S.S.E. of Tchao-king.

SINIA, a river of Ruſſia, which runs into the Oby, 52 miles N. of Berezov, N. lat. 65°. E. long. 66° 14′.

SINJAR, a town of Aſiatic Turkey, in the province of Diarbekir; 140 miles S.E. of Diarbekir. N. lat. 36° 17′. E. long. 41° 35′.—Alſo, a range of mountains, in the province of Diarbekir; 70 miles S.E. of Diarbekir. On this range ſtood the fortreſs of Sangara, which was ſurrendered to the Perſians by the puſillanimous ſucceſſor of Julian, about eight or ten miles from Niſibis. This mountain is at preſent peopled by ſeveral tribes of that ſect called Yezedi, who worſhip, or rather deprecate, the devil, from a notion that he poſſeſſes an unlimited power over mankind. They are the deſcendants of thoſe Arabs who followed the banners of Yezid, and fought againſt Haſſein, in the battle of Kerbela; and Sheikh Ade, the founder of the ſect, is interred near Moſul. They are ſaid to adore the Supreme Being as the creator and benefactor of the human race, drink wine and other ſtrong liquors, and circumciſe like the Mahometans. They are the mortal enemies of the Turks, and have never been completely ſubdued. They lie in ambuſh behind the riſing grounds, which ſkirt the road between Moſul and Merdin; and as travellers are obliged to paſs a lonely wild, 20 furſungs in length, they are liable, if not numerouſly attended, to be murdered by theſe miſcreants. Sinjar affords abundance of paſturage, and alſo a ſufficient quantity of grain for the conſumption of its ſavage inhabitants. In the year 341 a bloody battle was fought near this place, between the emperor Conſtantius and Sapor II., in which the former ſuſtained a total defeat, and was driven by his victorious rival acroſs the Euphrates.

SINIA STANITZ, a town of Ruſſia, in the government of Irkutſk, on the Lena. N. lat. 61° 15′. E. long. 125° 34′.

SINICA, a town of America, in South Carolina, belonging to the Cherokee Indians, on the Keowe; 43 miles N.W. of Peterſburg.

SINICAL QUADRANT. See QUADRANT.

SINIGAGLIA, in *Geography,* a ſea-port town of Italy, in the duchy of Urbino, the ſee of a biſhop, ſuffragan of Urbino, on the Adriatic, at the mouth of the river Nivola (anciently Senon), which ſeparates the duchy of Urbino from the marquiſate of Ancona. It was anciently called "Sena Gallorum," denoting that it was built by the Gallic Senones, and became a Roman colony in the year of Rome 462. It has been ſeveral times deſtroyed, eſpecially by the Goths. It contains four churches and ſix convents, with about 6000 inhabitants. It is an unhealthy place, and water fit for drinking is ſcarce ; 28 miles E.S.E. of Urbino.

SINJIAR. See SINJAR.

SIN-ING, a town of Corea ; 25 miles E.S.E. of Long-Kouang.

SI-NING, a town of Corea ; 8 miles N.E. of Sing-tcheou.—Alſo, a city of China, of the ſecond rank, in Chen-ſi. N. lat. 36° 40′. E. long. 101° 24′.—Alſo, a town of China, of the third rank, in Pe-tche-li ; 25 miles N.W. of Yu-tcheou.—Alſo, a town of China, of the third rank, in Quang-tong ; 15 miles S.W. of Te-king.

SINION, a river of China, which runs into the Kialing, 15 miles S. of Oei-tcheou.

SINIS COLONIA, in *Ancient Geography,* a town of Aſia, in Leſſer Armenia, near the Euphrates, according to Ammianus Marcellinus.

SINISCOLA, in *Geography,* a town of Sardinia, on the eaſt coaſt. N. lat. 40° 30′. E. long. 10° 1′.

SINISI, a town of Naples, in Baſilicata ; 11 miles S.W. of Turſi.

SINISTER, ſomething on, or towards the left hand.

Hence ſome derive the word ſiniſter, *a ſinendo,* becauſe the gods, by ſuch auguries, permit us to proceed in our deſigns.

SINISTER is alſo uſed among us for unlucky ; though, in the ſacred rites of divination, the Romans uſed it in an oppoſite ſenſe. Thus, *avis ſiniſtra,* or a bird on the left hand, was eſteemed a happy omen ; whence, in the law of the Twelve Tables, *Ave ſiniſtra populi magiſter eſto.*

SINISTER, in *Heraldry.* The ſiniſter ſide of an eſcutcheon is the ſide anſwering to the right hand of the perſon who looks at it.

SINISTER *Chief* and *Baſe.* See ESCUTCHEON.

SINISTER *Bend.* See BEND.

SINISTER *Aſpect,* among *Aſtrologers,* is an appearance of two planets, happening according to the ſucceſſion of the ſigns ; as Saturn in Aries, and Mars in the ſame degree of Gemini.

SINISTRI, a ſect of ancient heretics, thus called, becauſe they held the left hand in abhorrence, and made it a point of religion not to receive any thing with it.

What in us is a piece of civility, in them was a ſuperſtition. Balſamon obſerves, that they were likewiſe called Sabbatians and Novatians.

SINKBAZAR, in *Geography,* a town of Bengal ; 15 miles S.S.W. of Rogonatpour.

SINKEL, a ſea-port town of the iſland of Sumatra, near the weſt coaſt, on a river which runs into the ſea. This town is a good mart for ſalt, iron, ſteel, and ſometimes opium. N. lat. 2° 8′. E. long. 97°.

SINKING *of the Earth.* See ABSORPTIONS *of the Earth.*

SINKING *Fund.* See FUND.

SINKOO, in the *Materia Medica,* a name given by ſome authors to the lignum aloes, or agallochum, uſed in medicine.

SINKOUANG, in *Geography,* a town on the weſt coaſt of Sumatra. N. lat. 1° 12′. E. long. 98° 13′.

SIN-LO, a town of China, of the third rank, in Petche-li, on the Chao river ; 42 miles S.W. of Pao-ting.

SINN, a river of Germany, which runs into the Maine, with the Saal, near Gemunden, in the duchy of Wurzburg. —Alſo, a town of Aſiatic Turkey, in the province of Diarbekir ; 40 miles S.E. of Diarbekir.

SINNEMAHONING CREEK, a river of America, in Pennſylvania, which runs into the weſt branch of the Suſquehanna, N. lat. 41° 17′. W. long. 78°.

SINNERSHAUSEN, a town of Germany, in the county of Henneberg ; 8 miles N.W. of Meinungen.

SINNET, aboard a *Ship.* See SENNIT.

SIN-NGHAN, in *Geography,* a town of China, of the third rank, in Ho-nan ; 17 miles W. of Ho-nan.

SIN-NHING, a town of China, of the third rank, in Hou-quang ; 20 miles S.S.W. of Oukang.

SIN-NING, a town of China, of the third rank, in Quang-tong ; 52 miles S. of Tchao-king.—Alſo, a town of China, of the third rank, in Se-tchuen ; 17 miles E.S.E. of Ta.—Alſo, a city of China, of the ſecond rank, in Quang-ſi. N. lat. 22° 34′. E. long. 107° 17′.

SINNO, a river of Naples, which runs into the Adriatic, N. lat. 40°. E. long. 16° 40′. Near the mouth of the Sinno was Siris, probably the port of Heraclea ; but at preſent there is nothing but an open road, where ſhips may lie to take in a cargo of corn, and other commodities, of which one is liquorice, a root that grows wild in great quantities along theſe ſwamps, and the ſale of which is ſaid to have produced 700*l.* a year to the duke of Corigliano. The banks of the Sinno are famous in Roman hiſtory for the victory gained by Pyrrhus over the conſul Levinus, in the year of Rome 473. This is ſaid to have been the firſt encounter of the Epirots with the Romans. The honour of the day was purchaſed by Pyrrhus at the expence of the flower of his army.

SINO, a town of Africa, on the Grain Coaſt ; 30 miles S.E. of Sanguin.

SINOB, or SINOPE, a ſea-port town of Aſiatic Turkey, in the ſangiacat of Kiutaja, near the coaſt of the Black ſea, on the iſthmus of a peninſula, ſix miles in circumference, which terminates in a conſiderable cape, which has not above twelve feet of water. The antiquity of this town is traced to the time of the Argonauts, or at leaſt to the time when the Cimmerians eſtabliſhed themſelves here ; for being driven from their country by the Scythians, they came into Aſia, overagainſt the mouth of the Iſter. Its firſt commencement, however, was feeble ; but when it received a colony of Mileſians, it roſe to ſuch a degree of power, that it founded other colonies on the coaſts of the Euxine ſea, whilſt it poſſeſſed all the advantages of liberty. It was taken by Pharnaces, father of Mithridates, and made the capital of Pontus ; and it became the birth-place of Mithridates. In the year B.C. 70, it was taken by the Romans under Lucullus, who reſtored its liberty. After experiencing a variety of calamities under the tyranny of Pharnaces, Julius Cæſar, having vanquiſhed this prince, re-eſtabliſhed Sinope, and ſent hither a Roman colony. It eſtabliſhed a new era in commemoration of this happy event, and inſcribed on its monuments the title of "Colonia Julia Felix Sinope." This colony was ſent to Sinope in the year of Rome 709. The town ſubſiſted in a flouriſhing ſtate under the Roman emperors. Its commerce, which was conſiderable, and the convenience of its ports, contributed alike to its opulence and its ſplendour. Strabo ſays that it was one of the moſt conſiderable towns of Aſia. A particular worſhip was paid to Serapis at Sinope, and it alſo honoured Mercury as the god of commerce. Strabo and Pliny ſay, that Sinope, under the Roman emperors, compriſed in Paphlagonia, formed a part of the government of Bithynia. Paphlagonia, however, was detached from Bithynia, and formed a particular province, about the reign of Conſtantine ; but the town of Sinope was united with ſome other towns of Pontus, to form the province of Helleſpont, in honour of Helena, the mother of Conſtantine. When the emperor Heraclius divided the Eaſt into ſeveral departments, the town of Sinope was included in that of Armenia. Chriſtianity was received in this city towards the end of the third century. This place has two good harbours, and a dock-yard for building ſhips. Turks only reſide within the walls; one of the fauxbourgs is inhabited by Greeks, with a metropolitan dependant on the patriarch of Conſtantinople. In the environs are ſome copper-mines. Diogenes, the cynic, was a native of Sinope, but he was buried at Corinth; 380 miles E. of Conſtantinople. N. lat. 41° 6′. E. long. 35°.

SINON, a river of Perſia, in the province of Mazanderan, which runs into the Caſpian ſea, 5 miles E. of Fehrabad.

SINONGI, a town of Japan, in the iſland of Ximo; 20 miles S.W. of Sanga.

SI NON OMNES, in *Law*, a writ on aſſociation of juſtices, by which, if all in commiſſion cannot meet at the day aſſigned, it is permitted that two or more of them may finiſh the buſineſs.

SINOOTS, in *Geography*, a town of Japan, in the iſland of Ximo; 20 miles E. of Taiſero.

SINOPE, in *Ancient Geography*. See Sinob.

Sinope, a river of Aſia, in Paphlagonia, which runs near the town of Sinope.

SINOPER, or Sinopis, in *Natural Hiſtory*. See Sinopica *Terra*.

SINOPICA Terra, the name of a red earth, of the ochre-kind, called alſo *rubrica ſinopica*, and by ſome authors *ſinopis*.

It is a very cloſe, compact, and weighty earth, of a fine glowing purple colour, but in ſome ſpecimens much deeper than in others, and in ſome degenerates into paleneſs; but, even in its worſt condition, the colour is very fine. It is of a pure texture, but not very hard, and of an even but duſty ſurface. It adheres firmly to the tongue, is perfectly fine and ſmooth to the touch, does not crumble eaſily between the fingers, and ſtains the hands. It melts very ſlowly in the mouth, and is perfectly pure and fine, and of a very auſtere aſtringent taſte, and ferments very violently with aqua fortis. In the fire it acquires a great hardneſs, but does not change colour.

It was dug in Cappadocia, and carried for ſale to the city Sinope, whence it had its name. It is now found in plenty in the New Jerſeys, in America, and is called by the people there *blood-ſtone*, from its ſtaining the hands to a blood-colour, and may probably be had in many other places; and this deſerves thoroughly inquiring into, ſince there ſeems not one among the earths more worthy of notice. Its fine texture and body, with its high florid colour, muſt make it very valuable to painters, and its powerfully aſtringency equally ſo in medicine.

The ancients were well acquainted with it in fluxes and hæmorrhages, and experience ſhews it poſſeſſes the ſame virtues at this time. The deepeſt coloured is ever the moſt aſtringent. Hill's Hiſt. of Foſſ. p. 60.

SINOPLE, or Senople, in *Heraldry*, denotes *vert*, or the green colour in armories; thus called by the ancient heralds: though Pliny and Iſidore, by *color ſinopicus*, or *ſinople*, mean a browniſh-red, ſuch as that of our ruddle.

F. Meneſtrier derives the word from the Greek *praſina hopla*, *green armories*; by corruptedly retrenching the firſt ſyllable *pra*; which is no new thing among Oriental words, witneſs Salonica for Theſſalonica.

Sinople is ſuppoſed to ſignify love, youth, beauty, rejoicing, and liberty: whence it is, that letters of grace, abolition, legitimation, &c. are always to be ſealed with green wax.

SINOPOLI, in *Geography*, a town of Naples, in Calabria Ultra; 5 miles S.W. of Oppido.

SINOTIUM, in *Ancient Geography*, a town of Illyria, in Dalmatia, and one of the fifty poſſeſſed by the Dalmatians. Strabo ſays, that it was reduced to aſhes by Auguſtus.

SINOVIA. See Synovia.

SIN-PING, in *Geography*, a town of China, of the third rank, in Yun-nan; 35 miles N. of Yuen-kiang.

SINSACATA, a town of South America, in the province of Cordova; 36 miles N. of Cordova.

SIN-SI, a town of Corea; 30 miles N.N.E. of King-ki-tao.

SINSJA, a river of Aſia, which runs into the Euphrates, 33 miles S.E. of Semiſat.

SINSILIN, a town of Perſia, in the province of Ghilan; 23 miles W.N.W. of Reſhd.

SINSIN, a town of Perſia, in the province of Irak; 120 miles N. of Iſpahan. See Zinjan.

SINSO, a province of Africa, in the kingdom of Angola, north of Loanda.

SIN-TAI, a town of China, of the third rank, in Chantong; 37 miles S.E. of Tai-nghan.

SIN-TAI-TOUKA, a town of Chineſe Tartary. N. lat. 41° 16′. E. long. 120° 14′.

SIN-TAN, a town of China, of the third rank, in Se-tchuen; 10 miles S.S.E. of Han.

SIN-TCHANG, a town of Corea; 45 miles E. of Haimen.—Alſo, a town of China, of the third rank, in Kiang-ſi; 37 miles W.S.W. of Choui-tcheou.—Alſo, a town of China, of the third rank, in Tche-kiang; 42 miles N.N.W. of Tai-tcheou.—Alſo, a city of China, of the ſecond rank, in Yun-nan. N. lat. 29°. E. long. 103° 29′.

SIN-TCHEOU, a city of China, of the firſt rank, in Quang-ſi. N. lat. 33° 26′. E. long. 109° 29′.

SIN-TCHIM HOTUN, a city of Corea. N. lat. 42° 57′. E. long. 130° 18′.

SIN-TCHIN, a town of China, of the third rank, in Pe-tche-li; 32 miles N.E. of Pao-ting.—Alſo, a town of China, of the third rank, in Chan-tong; 30 miles N.W. of Tcin-tcheou.

SIN-TCHING, a town of China, of the third rank, in Kiang-ſi; 22 miles S.S.E. of Kien-tchang.—Alſo, a town of China, of the third rank, in Tche-kiang; 30 miles N.N.E. of Yen-tcheou.—Alſo, a town of China, of the third rank, in Se-tchuen; 17 miles E. of Xun.—Alſo, a town of China, of the third rank, in Ho-nan; 20 miles N. of Hiu-tcheou.

SIN-TCHU-AM, a town of Chineſe Tartary. N. lat. 41° 5′. E. long. 120° 54′.

SIN-TCHUEN, a town of Corea; 48 miles S.W. of Hoang-tcheou.

SIN-TCIN, a town of China, of the third rank, in Houquang; 20 miles W.S.W. of Koue-yang.

SINTHUS, in *Ancient Geography*, a town of Macedonia, in the Amphaxitide, near the gulf Thermæus, according to Herodotus.—Alſo, one of the largeſt rivers which diſcharged themſelves into the Erythræan ſea. Arrian.—Alſo, one of the mouths of the Indus, according to Ptolemy.

SIN-TIEN, in *Geography*, a city of China, of the ſecond rank, in Yun-nan. N. lat. 25° 36′. E. long. 102° 54′.

SIN-TIENTSE, a town of Chineſe Tartary. N. lat. 41° 16′. E. long. 121° 19′.

SINTII, in *Ancient Geography*, the name of a people who inhabited the iſle of Lemnos, according to Homer. This name, however, probably belongs to the inhabitants of the town of Sindus, or Sinthus, near the Thermaic gulf.

SINTIQUIPAQUE, in *Geography*, a town of Mexico, in the province of Guadalajara, on the Barania; 110 miles N.W. of Guadalajara.

SIN-TOU, a town of China, of the third rank, in Kiang-ſi, on the river Kan; 13 miles S. of Lin-kiang.—Alſo, a town of China, of the third rank, in Se-tchuen; 10 miles S. of Han.

SINTRA. See CINTRA.

SIN-TSAI, a town of China, of the third rank, in Ho-nan, on the river Yu; 32 miles E.S.E. of Yun-hing.

SINTZHEIM, a town of the duchy of Baden; 13 miles S.S.E. of Heidelberg.

SINU. See ZINU.

SINUATUM FOLIUM, in *Botany*, a Sinuated Leaf, ſo called from *ſinus*, a bay or creek, in alluſion to its winding outline, or the broad, deep, rounded inciſions of its margin. See LEAF.

SINUESSA, in *Ancient Geography*, a town of Italy, on the frontiers of Latium and Campania, near the marſh of Miſturnes. It derived its name, according to Strabo, from the ſinuoſity of the coaſt, which at this place formed a ſmall gulf. Some remains of it, as well as of its baths, the water of which was reputed to be excellent againſt ſterility, ſtill ſubſiſt. Sinueſſa was a Roman colony, according to Livy.

SINUNIA, a town of Aſia, in Parthia, according to Ptolemy.

SINUOSITY, a ſeries of bends and turns in arches, or other irregular figures; ſometimes jetting out, and ſometimes falling in: ſuch as deſcribed by the motion of a ſerpent, &c.

It is the ſinuoſity of the ſea-coaſts that forms bays, ports, capes, &c. Du Loir obſerves, that the courſe of the river Meander, creeping in a thouſand agreeable ſinuoſities, ſerved Dædalus as a model by which to form his labyrinth.

SINUOUS ULCERS. See ULCER.

SINUS, in *Anatomy*, a term applied to various cavities of the body. In the head we have the ſinuſes of the frontal, ſphenoid, ethmoid, and maxillary bones; which are cavities of theſe bones communicating with the noſe. (See CRANIUM and NOSE.) The ſinuſes of the dura mater are the large veins of the brain. (See BRAIN, NERVOUS *Syſtem*, and VEIN.) The ſinuſes of the venæ and cavæ and pulmonary veins are the principal parts of the two auricles. (See HEART.) The ſinus of the vena portarum is its trunk, juſt before it divides into the right and left branches. See VEIN.

SINUS, in *Surgery*, a ſmall orifice leading down to an abſceſs.

SINUS *Hipponenſis*, in *Ancient Geography*, the gulf of Bizerta, a gulf of Africa, formed by the promontory "Candidum" to the north-weſt, and the promontory "Apollinis" to the eaſt.

SINUS *Numidicus*, the gulf of Stora, a gulf of Africa, formed to the weſt by the promontory "Tritum," and to the eaſt by the promontory "Tapſus."

SIN-YAN, in *Geography*, a river of China, which runs into the Eaſtern ſea, 17 miles E.N.E. of Yen-te-hing.

SIN-YANG, a town of Corea; 45 miles S. of Koang-tcheou.—Alſo, a city of China, of the ſecond rank, in Ho-nan. N. lat. 32° 12′. E. long. 113° 38′.

SIN-YE, a town of China, of the third rank, in Ho-nan; 27 miles S.S.W. of Nan-yang.

SIN-YU, a town of China, of the third rank, in Kiang-ſi; 25 miles W.S.W. of Lin-kiang.

SINZIG. See ZINZIG.

SINZITA, in *Ancient Geography*, a town of Leſſer Armenia, in the prefecture of Muriana. Ptolemy.

SIO, in *Geography*, a river of Hungary, which runs into the Sarand, near Simontornya.—Alſo, a river of Spain, which runs into the Segra, a little above Balaguer.—Alſo, a decayed town of Africa, on the coaſt of Zanguebar; 10 miles N.W. of Ampaça.

SIOCON, a town on the weſt coaſt of the iſland of Mindanao. N. lat. 7° 25′. E. long. 122° 12′.

SIOCOTTICLAY, a town of the iſland of Ceylon; 25 miles N.N.W. of Trincomaly.

SIODA, in *Ancient Geography*, a town of Albania, being one of thoſe which Ptolemy places between the Cyrrhus and Albanus.

SIOE, in *Geography*, a ſmall iſland of Denmark, near the W. coaſt of Langeland. N. lat. 54° 58′. E. long. 10° 42′.

SION, or ZION, in *Ancient Geography*, a mountain of Paleſtine, or of the land of Canaan, for an account of which, ſee JERUSALEM.

SION was alſo one of the names of mount Hermon, or rather of a chain of mountains, called mountains of Hermon, from mount Hermon, the principal of them. Of this mountain the Pſalmiſt probably ſpeaks in Pſ. cxxviii. 3.—Alſo, a town of Paleſtine, in the tribe of Iſſachar, according to the book of Joſhua.

SION, in *Geography*, a town of France, in the department of the Lower Loire; 9 miles W. of Chateaubriant.

SION, or *Sitten*, a town of Switzerland, and capital of the Vallais, ſituated on a river of the ſame name, which ſoon after runs into the Rhone. This is the ſee of a biſhop, the moſt ancient in Switzerland, and ſaid to have been originally founded at Martinach. The biſhop, who ſtyles himſelf count and vogt-governor of the Vallais, is elected by the chapter of the cathedral and the repreſentatives of the tythings, and is a ſuffragan of the archbiſhop of Mouſtiers, in Savoy. It contains ſix churches, with ſome convents, a college, and three palaces of the biſhop, ſtanding one above another; 48 miles E. of Geneva. Sion is ſituated at the foot of three inſulated rocks, that riſe immediately from the plain. The higheſt, called Tourbillon, ſupports the ruins of the old epiſcopal palace, containing two or three untenanted apartments, in one of which are the portraits of the ſeveral biſhops. On the ſecond rock, denominated Valeria, are obſerved the remains of the old cathedral, and a few houſes belonging to the canons. On Mayoria, the third rock, ſtands the epiſcopal palace, an ancient edifice of ſtone, built in 1547. Two apartments in this palace deſerve attention. The firſt is that in which the diet aſſembles; and the other is the hall, in which the biſhop holds his court, like the feudal lords of ancient times; at the further extremity is a raiſed ſeat, called a throne, ſurrounded by a wooden baluſtrade, and as an incitement to wiſdom and impartiality, the figures of Juſtice and Solomon's judgment are coarſely painted upon the walls. Sion is an ancient town, and was formerly the capital of the Seduni, who inhabited this part of the country in the time of Julius Cæſar. Among ſeveral obliterated inſcriptions, one is legible, in honour of the emperor Auguſtus, during his eleventh conſulſhip. In this inſcription the town is called "Civitas Sedunorum." N. lat. 46° 11′. E. long. 7° 9′. See VALLAIS.

SION *College*. See COLLEGE.

SIONDELAR, in *Geography*, a town of Hindooſtan, in the Carnatic; 25 miles N.W. of Ongole.

SIONDY, a town of Hindooſtan, in the Carnatic; 20 miles S. of Ongole.

SIONE, a river of America, which runs into lake Erie, N. lat. 42° 22′. W. long. 82° 52′.

SIONI, a town of Georgia, in the province of Carduel; 90 miles N.N.W. of Teflis.

SIOPE, a river of Brazil, which runs into the Atlantic, S. lat. 3° 20′. W. long. 40′.

SIORING, a town of North Jutland; 4 miles N.W. of Tiſted.

SIOTO. See Scioto.

SIOTOSTA, a town of Sweden, in Weſt Gothland; 49 miles E.S.E. of Gotheborg.

SIOUEN, a town of China, of the third rank, in Quang-tong; 32 miles S. of Louy.

SIOULE, a river of France, which runs into the Allier, two miles N. of St. Pourçain, in the department of the Allier.

SIOU-OUEN, a town of China, of the third rank, in Koei-tcheou; 15 miles N.N.W. of Koei-yang.

SIOUX, a river of Louiſiana, which runs into the Miſſouri, N. lat. 38° 42′. W. long. 93° 17′.

Sioux, a denomination that diſtinguiſhes Indians of North America, who inhabit the territories about the rivers Miſſiſippi and Miſſouri. The dread of this powerful nation is extended over all the other ſavage nations, from the confluence of the Miſſiſippi and Miſſouri, to the Raven river on the former, and to the Snake Indians on the latter. Among theſe nations, however, the Sioux have many allies; but the Chippeways are an exception, as they have maintained with them a long conteſt; and, indeed, by means of their ſmall lakes, water-courſes, and impenetrable moraſſes and ſwamps, they bid defiance to the attacks of their neighbours. Of the Sioux nation there are different bands, that are diſtinguiſhed among themſelves. The firſt of theſe comprehends the Minowa Kantong, or Gens de Lac, who extend from the Prairie des Chiens to Le Prairie du François, 35 miles up the St. Peters. This band is again ſubdivided into four claſſes, under different chiefs. The firſt ſubdiviſion hunts on both ſides of the Miſſiſippi and its confluent ſtreams, from the Prairie des Chiens to the river Du Bœuf. The ſecond ſubdiviſion reſides near the head of the lake Pepin, and hunts from the Rivière du Bœuf near to the river St. Croix. The third ſubdiviſion reſides between the Rivière au Canon and the entrance of the St. Peters. Its principal hunting ground is on the St. Croix. The fourth ſubdiviſion is ſituated from the entrance of St. Peters to the Prairie des François; they have a village nine miles up the St. Peters, on the N. ſide. The band Minowa Kantong is reputed the braveſt of all the Sioux. The ſecond band of Sioux includes the Waſhpetong, or Gens des Fieulles, who inhabit the country from the Prairie des François near to Roche Blanche, on the St. Peters. They hunt on the St. Peters, and alſo in the Miſſiſippi up Rum river, and ſometimes follow the buffalo over the plains. The third band compriſes the Suſſitongs, who extend from the Roche Blanche to Lac de Groſs Roche, on the river St. Peters. They are ſubdivided into the Cawrees and Suſſitongs proper, both of whom hunt E. of the Miſſiſippi, and up that river, as far as the Rivière de Corbeau. The fourth great band comprehends the Yanctongs, who are diſperſed from the Montaignes de la Prairie, which extend from St. Peters to the Miſſouri, to the river De Moyen. Theſe are ſubdivided into the Yanctongs of the north and thoſe of the ſouth. Theſe are the moſt unſettled and erratic of all the Sioux; ſo that they are ſometimes found on the borders of the Lower Red river, ſometimes on the Miſſouri, and on thoſe immenſe plains that lie between the two rivers. The fifth band includes the Titongs, who are diſperſed on both ſides of the Miſſouri. The ſixth and ſmalleſt band of the Sioux includes the Waſhpecoute, who reſide generally on the lands weſt of the Miſſiſippi, between that river and the Miſſouri. They generally hunt on the head of the river De Moyen. Theſe are repreſented as the moſt ſtupid and inactive of all the Sioux.

The Minowa Kantongs are the only Sioux who uſe canoes, and they are by far the moſt civilized; being the only Sioux who have ever built log huts, or cultivated any ſpecies of vegetables. This band is entirely armed with fire-arms. The Waſhpetong are a roving band; they leave the river St. Peters in April, and do not return from the plains until the middle of Auguſt. The Suſſitongs of Roche Blanche bear the character of being the moſt evil-diſpoſed Indians on the river St. Peters. They likewiſe follow the buffalo in the ſpring and ſummer months. The Suſſitongs of the Lac de Groſs Roche bear the character of good hunters and brave warriors. The Yanctongs and Titongs are the moſt independent Indians; as they follow the buffalo where chance directs; clothing themſelves with the ſkin, and making their lodges, bridles, and ſaddles of the ſame materials, the fleſh of the animal furniſhing them with food.

The claims of limits of the Sioux nation are allowed by all their neighbours to commence at the Prairie des Chiens, and to aſcend the Miſſiſippi, on both ſides, to the Rivière de Corbeau, up the river to its ſource; from thence to the ſource of St. Peters; from thence to the Montaigne de la Prairie; from thence to the Miſſouri, down that river to the Mahas, bearing thence N.E. to the ſource of the river De Moyen; and from thence to the place of commencement. They alſo claim a large territory S. of the Miſſouri. The country E. of the Miſſiſippi, from Rum river to the Rivière de Corbeau, is likewiſe in diſpute between them and the Chippeways, and has been the ſcene of many ſharp encounters for near 150 years paſt.

The Sioux are repreſented as the moſt warlike and independent nation of Indians within the boundaries of the United States, every paſſion being ſubſervient to that of war; and their leaders feel themſelves perfectly ſecure from any combination that can be made againſt them. Their guttural pronunciation, high cheek-bones, thin viſages, and diſtinct manners, together with their own traditions, ſupported by the teſtimony of neighbouring nations, leave little room for doubt, that they have emigrated from the N.W. point of America, to which they had come from the narrow ſtrait which in that quarter divides the two continents, and that they are deſcendants of a Tartarian tribe. Pike's Account of Expeditions to the Sources of the Miſſiſippi, &c. Appendix to part 1.

SIPA, a town of Napaul; 98 miles N.E. of Catmandu.

SIPALAY, a town on the W. coaſt of the iſland of Negroes. N. lat. 9° 43′. E. long. 122° 28′.

SIPANEA, in *Botany*, Aubl. Guian. 147. t. 56, a name of Aublet's, whoſe origin or meaning does not appear. The plant is ſuppoſed by Juſſieu to be a congener of *Muſſænda*; but Schreber more juſtly refers it to Virecta, Linn. Suppl. 17. See that article hereafter.

SIPARUNA, Aubl. Guian. 864. t. 333. Juſſ. 443, an unexplained name for a ſhrub of Guiana, whoſe generic characters are not ſufficiently made out to allow of its being reduced by Juſſieu to any of his natural orders; nor has Schreber admitted it into his *Genera Plantarum*. Aublet refers it to the *Monoecia Decandria* of the Linnæan ſyſtem.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in four deep roundiſh ſegments. *Cor.* none. *Stam.* Filaments four, ſix, eight, or ten, inſerted into a hairy receptacle; anthers of two cells. *Piſt.* none.

Female, *Cal.* and *Cor.* as in the male. *Stam.* none. *Piſt.* Germen ſuperior, roundiſh; ſtyle oblong, ſtriated; ſtigmas five, capillary. *Fruit* unknown.

1. S. *guianenſis.*—Found on the borders of rivulets, in the quarter of Oyac, flowering in Auguſt. The *ſtem* is eight or ten feet high, ſlender, with long, ſlender, ſmooth, oppoſite branches; its wood white and brittle. *Leaves* elliptic-oblong, ſmooth, pointed, entire, about five inches in length, oppoſite, on ſhort ſtalks. The *flowers* are axillary, green, very ſmall, on ſhort, ſomewhat racemoſe, ſtalks.

SIPAVEND, in *Geography*, a town of Perſia, in the province of Mekran; 212 miles N.N.W. of Kidge.

SIPELER, a town of Hindooſtan, in the circar of Condapilly; 24 miles S. of Maſulipatam.

SIPGICON-COUTEN, a town of Chineſe Tartary, in the country of Hami. N. lat. 40° 10′. E. long. 95° 42′.

SIPHAC, a name uſed by ſome authors for the peritoneum.

SIPHANTO, in *Geography*, an iſland of the Archipelago, N. of Argentiera, and very cloſe to it. In former times this iſland was flouriſhing under the name of "Siphnos," and it was even reckoned the richeſt of the Archipelago, on account of the gold and ſilver-mines which had there been diſcovered, and of which the tenth alone furniſhed the temple of Apollo at Delphos with the richeſt treaſure that had been ſeen. Theſe mines reflect diſhonour on the memory of the Siphnians, whilſt they enriched them; for their opulence produced ſuch a corruption of morals and duplicity of character, which became ſo common and ſo characteriſtic of them, that they ſerved, throughout all Greece, as a term of compariſon, when it was required to paint diſcredited morals or perfidy of conduct. At this day, the treaſures concealed within the boſom of the earth are unknown; and the diſcovery of them remains to become a ſource of riches to an iſland, which, though leſs impoveriſhed than ſome others, exhibits in a degree the picture of miſery common to all theſe countries. Beſides the mines of gold and ſilver which Siphanto afforded, it has ſome that are very abundant in lead, iron, and load-ſtone. Its mountains alſo contain quarries of very beautiful marble, and the reſidents ſpeak of a ſpecies of very ſoft ſtone, with which they made vaſes that were conveyed throughout all Greece, but are not known in our days; ſo that the iſland of Siphanto would ſtill be the richeſt of the Archipelago, if it ceaſed to be ſubject to a government which cruſhes it with an iron hand. It is alſo one of the moſt agreeable and moſt chearful; the air is pure and wholeſome; the plains are adorned with a variety of dreſs, which it owes to eaſy labour; and the excellent quality of their productions is another precious favour of nature. Salt, cotton, figs, oil, wax, and a few other commodities of leſs importance, compoſe the crops and the trade of the iſland: but both might be much augmented by induſtry, if it were encouraged. Fine cotton-cloths, ſtraw-hats, &c. are manufactured here. The inhabitants are mild and hoſpitable; the women are beautiful; but their dreſs diſguiſes their charms. This iſland has no harbour, except for ſmall veſſels. The moſt conſiderable place, which is called Serai, is built on ſteep rocks, which leave below the town only a ſmall cave, where boats can anchor, becauſe if they were ſurpriſed here by a northerly wind, they would ſoon be daſhed to pieces on the coaſt; thoſe of the country are haſtily drawn on ſhore as ſoon as they are unloaded. Siphanto contains five villages, and about 5000 inhabitants. N. lat. 36° 59′. E. long. 24° 56′.

SIPHILIS, from σιφλος, *filthy*, in *Surgery*, the venereal diſeaſe. See Lues *Venerea*.

SIPHITA, a word uſed by Paracelſus, and his followers, with the addition of *parva* and *magna*, for two diſorders. The *ſiphita parva* ſignifies the *chorea ſancti Viti*, or *St. Vitus's dance*; and the *ſiphita magna*, walking in time of ſleep.

SIPHNIUS Lapis, in the *Natural Hiſtory* of the ancients, a ſubſtance found in great plenty in the iſland Siphnos, (*Siphanto*,) in the Ægean ſea. It was dug up in large maſſes in the neighbourhood of the ſea; and when freſh, might be cut or worked into any ſorts of veſſels, by reaſon of its ſoftneſs; but when afterwards burnt and oiled over, became black and ſolid, and fit for any ſervice: and the veſſels made of it bore the fire very well. The ſame ſubſtance is ſtill found in many parts of Europe, and called *lapis lebitum*, and applied to the ſame uſe. It is no other than the ſteatites, or our ſoap-rock.

SIPHON, or Syphon, in *Hydraulics*, a crooked tube, one leg or branch of which is longer than the other; uſed in the raiſing of fluids, emptying of veſſels, and in various hydroſtatical experiments.

The word in the original Greek, σιφων, ſignifies ſimply *tube*, whence ſome apply it to common tubes or pipes. Wolfius particularly deſcribes two veſſels under the name of ſiphons: the one cylindrical in the middle, and conical at the two extremes; the other globular in the middle, with two narrow tubes fitted to it axis-wiſe: both ſerving to take up a quantity of water, &c. and to retain it when up.

But the moſt uſeful and celebrated ſiphon is that which follows: a crooked tube A B C (*Plate* XV. *Hydraulics*, *fig.* 1.) is provided of ſuch a length, and with ſuch an angle, or ſo bent at the vertex, as that when the orifice A is placed on an horizontal plane, the height of A B may not exceed thirty-two or thirty-three feet. For common uſes, a foot or half a foot high ſuffices. If, now, the leſs arm, A B, be immerged in water, or any other liquid, and the air be ſucked out of it by the aperture C, till the liquor follow; the liquor will continue to flow out of the veſſel, through the tube B C, as long as the aperture A is under the ſurface of the liquor.

Note, inſtead of ſucking out the air, the event will be the ſame, if the ſiphon be at firſt filled with the fluid, and the aperture C ſtopped with the finger, till the aperture A be immerged.

The truth of the phenomenon is known by abundance of experiments; nor is the reaſon of part of it far to ſeek. In ſucking, the air in the tube is rarefied, and the equilibrium deſtroyed; conſequently the water muſt be raiſed into the leſſer leg A B, by the preponderating preſſure of the atmoſphere.

The ſiphon being thus filled, the atmoſphere preſſes equally on each extremity, ſo as to ſuſtain an equal quantity of water in each leg; but the air not being able to ſuſtain all the water in the longer leg, and being more than able to ſuſtain that in the ſhorter leg; with the exceſs of force, therefore, it will raiſe new water into the ſhorter leg; and this new water cannot make its way, but by protruding the firſt before it: by this means is the water continually driven out at the longer leg, as it is continually raiſed by the ſhorter.

The cauſe of the ſiphon's running may be otherwiſe explained in the following manner: the air which paſſes into the veſſel A B C D (*fig.* 2.), repreſented by the column K L, K L, ſuſtains the column of water, L D, in the ſhort leg of the ſiphon, preſſing againſt that air with its perpendicular height D F; whilſt the column of air M S, preſſing upwards againſt the whole of the long or iſſuing leg D S, which acts according to the height D C, muſt yield and ſuffer the water to run out, as long as the leg D S is longer, or rather perpendicularly higher, than D G. For ſince K and M are ſuppoſed to be at the top of the atmoſphere, the columns K L and M S are equal in height and preſſure, (for the height of L above S is of no account with reſpect to the whole height of the atmoſphere,) as long as M S is acted upon by the deſcending water D S, whoſe height is from D to S, (*e. g.* fifteen inches,) an height ſuperior to that of the column D G, (*e. g.* ſeven inches,) ſupported by the column of air K L, the column M S muſt yield to the water iſſuing out at S; and however the ſurface of the water, E F, deſcends, the column K L, by its preſſure, will always overcome the reſiſtance of the column M S, becauſe it has a leſs height of water to ſuſtain than M S has. If the mouth of the iſſuing leg had been at T, the water would hang *in equilibrio*, filling both legs of the ſiphon, when the water is come down in the upper veſſel to I H T; becauſe then the two columns of air, K L and M S, will be acted againſt by an equal height of water in the legs of the ſiphon; but if you raiſe the iſſuing end of the ſiphon (now ſuppoſed at T) up to the level of *u* V above I H, the water will run back up from V to D, and ſo out at H in the upper veſſel: becauſe then the column M S, having only the height V D to ſuſtain, will be acted againſt with leſs force than the column K L, which is preſſed againſt by the whole height, D H, ſuperior to V D. Since, therefore, the preſſure of the air is the cauſe of the water being puſhed up into the ſiphon, and the difference of its preſſure (as one column is acted againſt by the water in the ſhort leg more weakly than another column of air is acted upon by the water in the long leg) is the cauſe of its running continually from one veſſel into another, when once ſet a-going; it follows, that the bend, D, of the upper part of the ſiphon muſt not be above thirty-two feet higher than the water in the upper veſſel, becauſe the air cannot ſuſtain a column of water, whoſe height exceeds thirty-two feet.

Mercury will run in a ſiphon in the ſame manner as water; but in this caſe, the bend of the ſiphon muſt not be more than $30\frac{8}{10}$ inches above the ſtagnant mercury in the upper veſſel; becauſe, as it is about fourteen times ſpecifically heavier than water, it will be lifted up by the preſſure of air but the fourteenth part of the height to which the water is lifted. Deſag. Exp. Phil. vol. ii. ſect. 8.

But ſome authors aſſert, that the water continues to flow through the ſiphon, even when placed under a receiver, and the air exhauſted from it.

Some will have it, that there is ſtill air enough left in the evacuated receiver, to raiſe the water to an inch or two. But as both mercury and water are found to fall entirely out of the Toricellian tube, *in vacuo;* the preſſure of the thin remaining air there can never be the cauſe of the aſcent, both of mercury and water, in the ſhorter leg of the ſiphon. Hence, as the height of the ſiphon is limited to thirty-two feet; for this only reaſon, that air cannot raiſe water higher; ſome have queſtioned whether or not we are in the right in rejecting Hero's method of carrying water, by means of a ſiphon, over the tops of mountains, into an oppoſite valley. For Hero only orders the apertures of the ſiphon to be ſtopped, and water to be poured through a funnel into the angle or meeting of the legs, till the ſiphon be full; when, ſhutting the aperture in the angle, and opening the other two, the water, he ſays, will continue to flow. Now, if there only need air for the firſt riſe of the water into the leſs leg, not for the continuation of the motion, it were poſſible to raiſe the water much higher than the height of the atmoſphere would carry it.

Wolfius (Elem. Matheſ. tom. ii. p. 348. ed. 1733.) expreſsly ſays, that this propoſed artifice of Hero is very juſtly rejected; becauſe air is neceſſary not only for the elevation of the water in the ſhorter leg, but for the continuance of its motion; and he adds, that this method was unſucceſsfully tried, where the height was greater than thirty-two feet.

Deſaguliers alſo obſerves, that in a crane or ſiphon, ſuch as that propoſed by Hero, of about forty feet high, the water, inſtead of running from the upper veſſel into the lower, as it would do if the height of the ſhort leg were much under thirty-two feet, will in the two legs fall back to the height of thirty-two feet, above the reſpective veſſels, where it will hang; the air not being able to ſuſtain the water above theſe heights, and conſequently drive it up over the bend.

In an experiment of this kind, the water in the legs of the ſiphon, unleſs it be purged of its air, will not reſt at a height of quite thirty feet above the water in the veſſels, becauſe air will extricate itſelf out of the water, and getting above the water in the legs, preſs it downwards, ſo that its height will be leſs to balance the preſſure of the atmoſphere. However, this is certain, that a ſiphon of a particular kind, once ſet a running, will perſiſt in its motion, though removed into the moſt perfect vacuum our air-pumps will make: or, if the lower orifice of a full ſiphon be ſhut, and the whole be thus placed in a receiver, with a contrivance for opening the orifice when the air is exhauſted; the water will be all emptied out of the veſſel, as if it had been in the open air.

This fact has been ſufficiently aſcertained by many approved hydroſtatical writers.

Deſaguliers informs us, that he made the experiment, both with water and mercury; for having filled a ſiphon, recurved at the extremities of its legs, ſucceſſively with thoſe liquors, and ſuſpended it by a ſlip-wire in the receiver of an air-pump, over two ſmall jars containing mercury to unequal heights, (and water, when water was uſed in the ſiphon,) he exhauſted the air out of the receiver, and then letting down the ſiphon, ſo that its two ends went into the liquor in the jars, the liquor ran from the higher into the lower veſſel. He alſo made an experiment in the open air, where the mercury ran through a ſiphon, whoſe bend was more than thirty-one inches above the lower orifice of the ſhort leg of the ſiphon. But neither of theſe experiments affords a juſt objection againſt the doctrine advanced in the preceding part of this article, *viz.* that the air is the cauſe of the diſcharge of liquors from one veſſel into another by means of ſiphons; for its running *in vacuo* was only owing to the attraction of coheſion, which acts for a ſmall height; becauſe the experiment will not ſucceed *in vacuo*, if the ſiphon uſed for mercury has its bend ſix inches higher than the orifice of the ſhort leg, and if the bend of the ſiphon for water be two or three feet high; neither will the laſt-mentioned experiment with mercury in the open air anſwer, if the bend of the ſiphon be forty inches high: and in all the experiments, the bores of the ſiphons muſt be very ſmall. Exp. Phil. ubi ſupra, p. 168.

The figure of the ſiphon may be varied at pleaſure (ſee *figs.* 3, 4, 5.), provided only the orifice C be below the level of the ſurface of the water to be drawn up; but ſtill the farther it is diſtant from it, the faſter will the fluid be carried off. And if, in the courſe of the flux, the orifice A be drawn out of the fluid, all the liquor in the ſiphon will go out at the lower orifice C; that in the leg C B dragging, as it were, that in the ſhorter leg A B after it.

If a filled ſiphon be ſo diſpoſed, as that both orifices, A and C, be in the ſame horizontal line, the fluid will remain pendant in each leg, how unequal ſoever the length of the legs may be. Fluids, therefore, in ſiphons, ſeem, as it were, to form one continued body; ſo that the heavier part, deſcending like a chain, pulls the lighter after it.

Laſtly, it muſt be obſerved, that the water will flow out, even through a ſiphon that is interrupted, by having the legs A D and F C joined (*fig.* 5.) together, by a much bigger tube full of air.

The ſipho Wirtembergicus is a very extraordinary machine of this kind, performing divers things which the common ſiphon will not reach. *E. gr.* In this, though the legs be in the ſame level, yet the water riſes up the one, and deſcends through the other; the water riſes, even though the aperture of the leſs leg be only half immerged in water; the ſiphon has its effect after continuing dry a long time; either of the apertures being open, the other remaining ſhut for a whole day, and then opened, the waters flow out as uſual. Laſtly, the water riſes and falls indifferently through either leg.

Muſchenbroeck, in accounting for the operation of this ſiphon, obſerves, no diſcharge could be made by it, unleſs the water applied to either leg cauſe the one to be ſhorter, and the other longer by its own weight. Introd. ad Phil. Nat. tom. ii. p. 853. ed. 4to. 1762.

The project of this ſiphon was laid by Jordanus Pelletier, and executed at the expence of prince Frederic Charles, adminiſtrator of Wirtemberg, by his mathematician Shahackard, who made each branch twenty feet long, and ſet them eighteen feet apart; the deſcription of it was publiſhed by Reiſelius, the duke's phyſician.

This gave occaſion to M. Papin to invent another, that did the ſame things, deſcribed in the Philoſophical Tranſactions; and which Reiſelius, in another paper in the Tranſactions, ingenuouſly owns to be the very ſame with that of Wirtemberg. Its ſtructure will appear from its figure, which is repreſented *Plate* XV. *Hydraulics*, *fig.* 6.

SIPHONANTHUS, in *Botany*, from σιφων, *a tube*, and ανθος, *a flower*, becauſe of the long tube of the corolla. Ammann, the author of the genus, in the Peterſburgh Tranſactions, for 1736, called it *Siphonanthemum*.—Linn. Gen. 53. Schreb. 70. Willd. Sp. Pl. v. 1. 606. Mart. Mill. Dict. v. 4. Juſſ. 132. Lamarck Illuſtr. t. 79.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Borragineis affine*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, large, in five deep permanent ſegments. *Cor.* of one petal, funnel-ſhaped; tube thread-ſhaped, very ſlender, many times longer than the calyx; limb in four deep ſpreading ſegments, ſmaller than the calyx. *Stam.* Filaments four, longer than the limb of the corolla; anthers oblong, triangular. *Piſt.* Germen ſuperior, four-cleft, very ſhort; ſtyle thread-ſhaped, the length of the ſtamens, recurved at the extremity; ſtigma ſimple. *Peric.* Berries four, roundiſh, within the ſpreading calyx. *Seeds* ſolitary, roundiſh.

Eſſ. Ch. Corolla of one petal, funnel-ſhaped, very long, inferior. Berries four, with ſolitary ſeeds.

1. S. *indica*. Indian Pipe-flower. Linn. Sp. Pl. 159. Willd. n. 1. Poiret in Lam. Dict. v. 7. 200. ("Siphonanthemum ſalicis folio, flore flaveſcente; Amm. Act. Petrop. ann. 1736, 214. t. 15." Lyſimachii ſpecies; Piſ. et Bont. Ind. Or. 159?)—Native of the Eaſt Indies? We have ſeen no ſpecimen, but the figures and deſcriptions of this plant repreſent it as having an herbaceous, ſimple, leafy *ſtem*. *Leaves* alternate, or partly oppoſite; ſometimes three in a whorl, ſeſſile, lanceolate, acute, wavy, entire. *Flower-ſtalks* axillary and terminal, much ſhorter than the leaves, three-cleft. *Flowers* thrice as long as their ſtalks, yellowiſh.

Willdenow has ſeparated Lamarck's fig. 2. as a diſtinct ſpecies, by the name of *S. anguſtifolia*; but Lamarck himſelf in his Illuſtr. p. 318, gives that figure as perhaps only a better repreſentation of the original ſpecies. The difference indeed between the ſtigmas of the two figures is too great to be probable. We ſhould think, with this author, that the figure in Bontius might rather belong to ſome *Volkameria* or *Clerodendrum*, were it not ſpoken of as a pot-herb. After all, who can be certain, that the hiſtory of *Siphonanthus* is not altogether a blunder, and that the original plant itſelf is not a *Volkameria*, *Clerodendrum*, or *Ovieda*? *O. mitis*, a ſpecies very little known to botaniſts in general, bears a conſiderable reſemblance to it, though the infloreſcence differs materially from what is deſcribed in *Siphonanthus*.

SIPHONIA, from σιφων, *a pipe*, alluding to the uſes made of the reſinous exudation of this tree, ſo well known under the appellation of elaſtic gum, or *caoutchouc*.—Schreb. Gen. 656. Willd. Sp. Pl. v. 4. 567. Mart. Mill. Dict. v. 4. Lamarck Illuſtr. t. 790. (Hevea; Aubl. Guian. 871.)—Claſs and order, *Monoecia Monadelphia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, bell-ſhaped, rather globoſe, cut half way down into five erect, acute teeth, reflexed at the margins. *Cor.* none. *Stam.* Filaments united into a column, ſhorter than the calyx; anthers five, nearly ovate, attached to the column below its ſummit.

Female, *Cal.* Perianth inferior, of one leaf, bell-ſhaped, ſomewhat turbinate, with five acute, ſpreading, recurved deciduous teeth, the circular baſe only being permanent. *Cor.* none. *Piſt.* Germen ſuperior, globoſe, ſomewhat conical, ſhorter than the calyx; ſtyle none; ſtigmas three, thickiſh, depreſſed, two-lobed. *Peric.* Capſule large, three-lobed, depreſſed, hollowed out at the baſe, woody, very hard, of three cells, inveſted with a fibrous bark; each cell with two elaſtic valves. *Seeds* one, two, or three, nearly ovate, with a brittle ſpotted ſhell.

Eſſ. Ch. Male, Calyx bell-ſhaped, five-cleft. Corolla none. Filament columnar, with five anthers.

Female, Calyx bell-ſhaped, five-cleft. Corolla none. Stigmas three, ſeſſile. Capſule of three lobes, with elaſtic valves.

1. S. *elaſtica*. Elaſtic-gum Tree. Martin n. 1. (S. Cahuchu; Richard. Willd. n. 1. Jatropha? elaſtica; Linn. Suppl. 422. Hevea guianenſis; Aubl. Guian. 871. t. 335. "Pao ſeringa; Mem. de l'Acad. des Sc. for 1751. t. 20, bad.")—Native of Braſil, and the foreſts of Guiana, bearing fruit in April and May. A *tree*, whoſe trunk riſes to the height of 50 or 60 feet, with a thin grey bark, and a ſoft white wood; the *branches* ſpreading widely in every direction. *Leaves* towards the ends of the branches, alternate, but crowded, and ſpreading in a circular order round the branch, on long ſtalks, ternate; leaflets elliptical, obtuſe, entire, or minutely undulated, ſmooth, reticulated with veins; paler beneath; each about three inches long, and one wide, on a partial ſtalk about half an inch in length. *Common footſtalks* rather longer than the leaflets, round, finely downy. The *flowers* we have not ſeen, but they are ſaid to be ſmall, downy, as well as their ſtalks; the male ones numerous, racemoſe; the female ſolitary, at

the end of each cluſter. *Fruit* the ſize of a cheſnut in its ſhell, green, ſmooth, of three large ovate lobes, the valves burſting elaſtically, like thoſe of a *Jatropha*. Aublet ſays the *nuts* are very good and wholeſome. The trunk of the tree, when wounded, diſcharges a milky fluid, which being collected, either in a maſs, or by ſmearing it over lumps of clay, ſticks, &c. dries into any ſhape that is wanted, and becomes the elaſtic gum, or Indian rubber, ſo uſeful to artiſts for effacing at pleaſure the marks of a black-lead pencil. (See Caoutchouc.) We beg leave to correct a ſlight botanical inaccuracy in that article; for the *Hevea* and the *Jatropha elaſtica* are preciſely the ſame plants. There is indeed, in the Linnæan herbarium, beſides the original ſpecimen, marked with this laſt name, another from Mutis, which that learned botaniſt judged to be a diſtinct ſpecies, though affording, as ſome other trees do, a ſimilar gum. The *leaflets* in this ſpecimen are larger, more acute at each end, and deſtitute of partial ſtalks. The *calyx* is nearly half an inch long. The younger Linnæus, in his *Supplementum*, 422, promiſed to publiſh ſomething at a future time reſpecting the various trees that yield an elaſtic gum, of the ſame utility as the *Caoutchouc;* but he did not live to execute his deſign. His reference to the Mem. de l'Academie for 1751, with a cenſure of the figure, appears to be copied from Aublet.

SIPIAS, in *Geography*, a town of Mingrelia, ſituated on a river which runs into the Black ſea; 100 miles W.N.W. of Teflis.

SI-PING, a town of China, of the third rank, in the province of Ho-nan; 30 miles N.N.W. of Yun-hing.

SIPONIMA, in *Botany*. See Ciponima, and Symplocos.

SIPSEY, in *Geography*, a river of the ſtate of Georgia, which runs into the Tombigh, N. lat. 32° 22′. W. long. 87° 51′.

SIPTACE, in *Natural Hiſtory*, the name given by the ancients to a beautiful bird, of which they were very fond, and which was often kept in their houſes. Some have conjectured this to be the goldfinch, from the fine yellow they deſcribe about it; but Pliny plainly makes it the parrot: he tells us, among other things, that it imitated the human voice the beſt of all birds.

SIPUCA, in *Geography*, a town of Peru, in the dioceſe of La Plata; 60 miles E. of Plata.

SIPUNCULUS, or Tube-worm, in *Vermiology*, a genus of the Vermes Inteſtina claſs and order, of which the generic character is as follows: Body round, elongated; mouth cylindrical at the end, and narrower than the body; the aperture at the ſide of the body, and veruciform. There are only two

Species.

* Nidus. The body of this ſpecies is covered with a cloſe ſkin, and globular at the lower end. It is deſcribed and figured by Pennant, Barbut, and Martin. It inhabits European ſeas, under ſtones; and is about eight inches long. The body is conic, and broader on the fore-part; the mouth is much ſlenderer than the body, and armed with fleſhy, three-pointed papillæ; the aperture is near the upper extremity.

Saccatus. Body covered with a looſe ſkin, and rounded at the lower end. It inhabits the American and Indian ſeas. It is ſhaped like the nidus, except in being encloſed as it were in a looſe bag, and in not having the lower end globular.

SIR, or Sirr, in *Geography*, a river which riſes in the mountains of Tartary, about 160 miles W. of Caſhgar, and runs into the lake of Aral, in N. lat. 45° 10′.

Sir *Biby's Iſland*, a ſmall iſland in Hudſon's bay. N. lat. 61° 55′. W. long. 93° 40′.

Sir *Charles Hardy's Iſland*, an iſland in the Southern Pacific ocean, diſcovered by captain Carteret in 1767. Its extent is conſiderable, and it appears to be flat, green, and pleaſant. S. lat. 4° 38′. E. long. 134° 6′.

Sir *Charles Hardy's Iſlands*, a cluſter of ſmall iſlands in the South Pacific ocean, diſcovered by captain Cook in 1770. S. lat. 11° 55′. W. long. 217°.

Sir *Thomas Hay's Point*, a cape on the N.W. coaſt of Portland, one of Queen Charlotte's iſlands, in the South Pacific ocean. S. lat. 10° 42′. E. long. 165° 14′.

Sir *William James's Iſland*. See St. *Suſanna*.

Sir *Henry Martin's Iſland*, an iſland in the Pacific ocean, about 16 leagues in circumference; diſcovered by lieutenant Hergeſt, commander of the Dædalus ſtore-ſhip, in the year 1792. The country ſeemed to be highly cultivated, and was fully inhabited by a civil and friendly race of people, readily inclined to ſupply whatever refreſhments their country afforded. Mr. Hergeſt's company were induced to entertain this opinion from the hoſpitable reception they experienced, on landing, from the chiefs, and upwards of 1500 of the natives, who were aſſembled on the ſhores of the harbour. On their return to the ſhip, they found the ſame harmony ſubſiſting there with the Indians, who had carried off and ſold a ſupply of vegetables and ſome figs. It is called by the natives Nooahēva. S. lat. 8° 51′. E. long. 220°.

Sir *Charles Saunders's Iſland*, or *Tapooamānoo*, an iſland in the Southern Pacific ocean, diſcovered by captain Wallis in the year 1767. The iſland is about ſix miles in length, and has a mountain of conſiderable height in the centre, which appeared to be fertile. The inhabitants did not appear to be numerous. S. lat. 17° 28′. W. long. 150° 40′.

Sir *Thomas Roe's Welcome*, a large bay in the north part of Hudſon's bay.

SIRA, a name by which ſome of the chemical writers have called orpiment.

SIRACAUSTUM, a name given by Meſue to a medicine he recommends in acute diſeaſes.

SIRACUSA, in *Geography*. See Syracusa.

SIRADIA, a town of the duchy of Warſaw, late capital of a palatinate of Poland, of the ſame name, ſituated on the Warta; 100 miles N.N.W. of Cracow. N. lat. 51° 31′. E. long. 18° 45′.

SIRÆUM, a word uſed by ſome to expreſs a ſweet decoction, whether given in that form, or firſt inſpiſſated into a ſort of rob by evaporation.

SIRAF, in *Geography*, a town of Perſia, in the province of Lariſtan, on the N. coaſt of the Perſian gulf, inhabited by Arabians from the oppoſite ſhores; 30 miles S.W. of Lar. N. lat. 26° 44′. E. long. 53° 50′.

SIRAGUAY, a town on the W. coaſt of the iſland of Mindanao. N. lat. 7° 15′. E. long. 112° 9′.

SIRAJEPOUR, a town of Hindooſtan, in Allahabad; 10 miles E. of Corah. N. lat. 26° 9′. E. long. 80° 58′.

SIRAITINA, a town of Ruſſia, in the country of the Coſſacks; 56 miles S. of Arkadinſkaia.

SIRAN, a town of France, in the department of the Herault; 15 miles S.W. of St. Pons.

SIRANCAPE, a river of Africa, which runs into the Indian ſea, S. lat. 13° 4′.—Alſo, a town of Africa, in the country of Mozambique, at the mouth of the river of the ſame name. S. lat. 13° 4′.

SIRANI, Giovanni Andrea, in *Biography*, a painter of the ſchool of Guido Rheni. He was born at Bologna in 1610, and was a favourite diſciple of his maſter, whoſe ſtyle he imitated with great ſucceſs. After the death of Guido, he was employed to finiſh many of his works, left incomplete in different churches, at Bologna; particularly the large picture of St. Brunone, in the Certoſini. He uſually painted upon a large ſcale, and with a free pencil, but in general his manner is too ſtrong and dark, like that of Caravaggio. He died in 1670, at the age of 60.

Sirani, Elizabetta, was the daughter of Giovanni Andrea Siraní, and born at Bologna in 1638. She learned the rudiments of the art from her father, but endeavoured to imitate the beſt ſtyle of Guido. At ſo early a period as her fifteenth year, ſhe had acquired conſiderable renown for her performances. Her firſt public work was painted when ſhe was only ſeventeen. In general ſhe wrought upon a large ſcale, and in a moſt finiſhed manner; with a rich and natural tone of colour. Her compoſitions are taſteful, and the airs of her heads graceful, and noble in character. Her portraits have greatly the air of nature, with an unaffected character of expreſſion and action.

Unhappily, whilſt in the enjoyment of the renown juſtly due to her ineſtimable talents and amiable qualities, and which had been acquired by unceaſing aſſiduity, her brilliant career was interrupted by poiſon; by whom adminiſtered is not exactly known, though it is ſuppoſed by her ſervant. This melancholy event happened in 1664, when ſhe had only attained her twenty-ſixth year; yet ſuch had been her induſtry, that ſhe had produced, according to Malvaſia, from a regiſter of her own keeping, 150 works: the moſt admired of which were painted for the churches and palaces at Bologna. They are elſewhere ſcarce.

SIRAN-LOSA, in *Geography*, a lake of Thibet, about 18 miles in circumference, which communicates with lake Tenckiri by means of a river called alſo "Siran-loſa;" 18 miles W. of lake Tenckiri.

SIRA-OULOSO, a town of Thibet; 15 miles E. of Hami.

SIRAT, Al, in the *Mahometan Theology*, the name of a bridge, which is ſituated in the midſt of hell, finer than a hair and ſharper than the edge of a ſword; over which thoſe who are admitted into paradiſe, and who take the right-hand way, and thoſe who are deſtined to hell-fire, and take the left, are ſuppoſed to paſs. On account of its form, it is conceived to be very difficult for any one to ſtand upon it; and therefore moſt of the Motazalites reject it as a fable, though the orthodox believe it on the authority of their prophet, by whom it is affirmed; and who has likewiſe declared, that in order to add to the difficulty of this paſſage, the bridge is beſet on each ſide with briars and hooked thorns, which will, however, be no impediment to the good, for they ſhall paſs with wonderful eaſe and ſwiftneſs, like lightning or the wind, Mohammed and his Moſlems leading the way; whereas the wicked, obſtructed by the ſlipppérineſs and extreme narrowneſs of the path, the entangling of the thorns, and the extinction of the light, which directed the former to paradiſe, will ſoon miſs their footing, and fall down headlong into hell, which is gaping beneath them. Koran, c. 18.

SIRATIK, in *Geography*, one of the Foulah ſtates in Africa, next in order to the principal, which lies within Sierra Leona, and of which Teambo is the capital. It borders on the ſouth of the Senegal river, and on the Jaloffs.

SIRAVAN, a town of Perſia, in the province of Chuſiſtan; 48 miles N.N.E. of Suſter.

SIRE, a title of honour in France, now given to the king only, as a mark of ſovereignty. In all placets and petitions, epiſtles, diſcourſes, &c. to the king, he is addreſſed under the title of *ſire*.

Some derive the word from the Latin *herus*, *maſter*: of which opinion ſeems Budæus, who, in ſpeaking to king Francis I., always called him *here*, q. d. *maſter*, or *ſire*; others derive it from the Greek κυριος, *lord*; of which opinion is Paſquier, who adds, that the ancient Franks gave the ſame title to God, calling him *beau ſire Dieu*: others fetch the word from the Syriac, and maintain it was firſt given to the merchants who traded in Syria: Menage will have it come from *ſenior*, *elder*; whence *ſeigneur*, then *ſeignor*, and *ſire*.

Sire was likewiſe anciently uſed in the ſame ſenſe with *ſieur* and *ſeigneur*, and applied to barons, gentlemen, and citizens.

Siré, in *Geography*, a province of Abyſſinia, about 25 miles broad, and not much more in length, reckoned as part of Tigré. It loſt the rank of a province, and was united to Tigré, on account of the miſbehaviour of its governor Kaſmeti Claudius, in an expedition againſt the Shangalla, in the reign of Yaſous the Great. It is ſeparated from Samen by the river Tacazzé, and reaches from Axum to this river.—Alſo, a town ſituated on the brink of a very ſteep, narrow valley, through which a road lies that is almoſt impaſſable. In the midſt of the valley runs a brook, bordered with palm-trees. The town of Siré is larger than that of Axum; it is in form of a half-crown fronting the plain, but its greateſt breadth is at the weſt end. All the houſes are of clay, and thatched; the roofs are in form of cones, as indeed are all in Abyſſinia. Siré is famous for a manufacture of coarſe cotton cloths, which paſs for current money through all the province of Tigré, and are valued at a drachm, the tenth part of a wakea of gold, or near the value of an imperial dollar each; their breadth is 1¼ yard. Beſides theſe, beads, needles, cohol, and incenſe, at times only, are conſidered as money. Although Siré is ſituated in one of the fineſt countries in the world, it is very ſubject to putrid fevers of the worſt kind, which ſweep away a number of people daily. N. lat. 14° 4′ 35″. E. long. 38° 0′ 15″. Bruce's Travels, vol. iii.

SIREN, σειρην, in *Antiquity*, *Mermaid*, a name given to a kind of fabulous beings, repreſented by the moderns as ſea-monſters, with women's faces and fiſhes' tails; but by the ancient poets, &c. as having the upper part human, and the lower like birds; and decked with a plumage of various colours. There are antique repreſentations of them ſtill ſubſiſting, under both theſe forms. They are ſaid to have been the daughters of Ocean and Amphitrite, and to form a beautiful part of Homer's machinery in the Odyſſey. Hyginus places their birth among the conſequences of the rape of Proſerpine. And Ovid makes them daughters of the river Achelous, and one of the Muſes.

The three ſirens are called *Parthenope*, *Lygea*, and *Leucoſia*. Homer only makes mention of two ſirens, and ſome others reckon five. Virgil places them on rocks, where veſſels are in danger of ſplitting. Pliny makes them inhabit the promontory of Minerva, near the iſland Capreæ. Others fix them in Sicily, near Cape Pelorus.

Claudian ſays, they inhabited harmonious rocks; that they were charming monſters; and that ſailors were wrecked on their rocks without regret, and even expired in raptures: *Dulce malum in pelago ſiren.*

Pauſanias tells us, that the ſirens, by the perſuaſion of Juno, challenged the Muſes to a trial of ſkill in ſinging; and theſe, having vanquiſhed them, plucked the golden feathers from the wings of the ſirens, and formed them into crowns, with which they adorned their own heads. This deſcription is, doubtleſs, founded on a literal explication of the fable, that the ſirens were women who inhabited the ſhores of Sicily; and who, by all the allurements of pleaſure, ſtopped paſſengers, and made them forget their courſe.

The name, according to Bochart, who derives it from the Phœnician language, implies a *ſongſtreſs:* and hence, it is probable, that in ancient times there might have been excellent ſingers, but of corrupt morals, on the coaſt of Sicily, who, by ſeducing voyagers, gave riſe to this fable. The Argonauts are ſaid to have been diverted from the inchantment of their ſongs, by the ſuperior ſtrains of Orpheus: Ulyſſes, however, had great difficulty in ſecuring himſelf from ſeduction. Circe prepares him for the conflict, by the picture and precepts deſcribed in the Odyſſ. lib. xii. ver. 51.

Some interpreters of the ancient fables will have the number and names of the three ſirens to have been taken from the triple pleaſure of the ſenſes, wine, love, and muſic, which are the three moſt powerful means of ſeducing men; and hence, ſo many exhortations to avoid the ſiren's fatal ſong.

Probably it was hence that the Greeks fetched their etymology of ſiren, *viz.* from σειρα, *a chain;* as if there was no getting free of their enticement.

Others, who do not look for ſo much myſtery in the fable, maintain that the ſirens were nothing but certain ſtraits in the ſea, where the waves whirling furiouſly around, ſeized and ſwallowed up veſſels that approached them too near.

Laſtly, others hold the ſirens to have been certain ſhores and promontories, where the winds, by the various reverberations and echoes, cauſe a kind of harmony that ſurpriſes and ſtops paſſengers. This, probably, might be the origin of the ſirens' ſong, and the occaſion of giving the name of ſirens to theſe rocks.

The learned Mr. Bryant ſays, that the ſirens were Cuthite and Canaanitiſh prieſts, who had founded temples in Sicily, which were rendered infamous on account of the women who officiated. They were much addicted to cruel rites, ſo that the ſhores upon which they reſided are deſcribed as covered with the bones of men, deſtroyed by their artifice. Virgil, Æneid, lib. i. v. 864.

The ancients repreſent their ſongs as ſo fatally winning, that nobody could withſtand their ſweetneſs: all were ſoothed with it; though their life was the purchaſe of the gratification. See Homer's Odyſſ. M. v. 39.

Mr. Bryant obſerves, that the ſtory of the ſirens relates to thoſe people, who with their muſic uſed to entice ſtrangers into the purlieus of their temples, and then put them to death. Nor was it muſic only with which perſons were ſeduced to follow them; the female part of their choirs were maintained for a twofold purpoſe, both on account of their voices and their beauty. They were accordingly very liberal of their favours, and by theſe means enticed ſea-faring perſons, who paid dear for their entertainment. Analyſis of Ancient Mythol. vol. ii. p. 17, &c.

SIREN, in *Ichthyology*, a name given by Artedi to the ſea-monſter often deſcribed by authors, but either not exiſting at all, or not ſo like man as their deſcription makes it. Artedi ſuppoſes it to conſtitute a peculiar genus of the plagiuri or cetaceous fiſhes. The characters he gives of it are theſe: it has no pinnated tail; the head, neck, and breaſt, down to the navel, repreſent thoſe of the human ſpecies; there are only two fins on the whole body, and thoſe ſtand on the breaſt.

Bartholine, in his Hiſtory of Curioſities, deſcribes ſuch a fiſh as this under the name of *ſyrene*, and Barchewitz under the name of *homo marinus*. See MERMAID, SEA-*Calf*, SEA-*Cow*, and SEA-*Man*.

SIREN, in *Natural Hiſtory*, a genus of the claſs and order Amphibia Reptilia, of which the generic character is, Body two-footed, tailed, naked; the feet are placed in the manner of arms, and furniſhed with claws. There is only a ſingle ſpecies mentioned by Gmelin, but Dr. Shaw notices three

Species.

LACERTINA. Body eel-ſhaped; branchiæ ramified. This ſpecies ſtands eminently diſtinguiſhed in the liſt of animals, by the ambiguity of its characters, which are ſuch as to have induced the great Linnæus to inſtitute it for a new order of Amphibia, under the title of MEANTES. The genus with which the ſiren has the neareſt affinity is the *lacerta*, or *lizard;* which ſee. It reſembles the larva, or firſt ſtate of a lacerta; and it is even ſtill doubtful whether it may not really be ſuch: yet it has never been obſerved in any other ſtate, having two feet only, without any appearance of a hind pair. The feet are alſo furniſhed with claws, whereas the larvæ of the lacertæ are obſerved to be without claws; the mouth has ſeveral rows of ſmall teeth; the body is eel-ſhaped, but ſlightly flattened beneath, marked on the ſides by ſeveral wrinkles, and ſlightly compreſſed towards the extremity of the tail, which is edged with a kind of ſoft ſkin, or adipoſe fin; on each ſide the neck are three ramified branchial proceſſes, reſembling, but on a larger ſcale, thoſe belonging to the larvæ of water-newts, and at the baſe are the openings into the gills; the eyes are very ſmall, and blue. The general colour of the animal is a deep or blackiſh-brown, ſcattered over, eſpecially on the ſides, with numerous minute whitiſh ſpecks. It is frequently found of the length of two feet, or even more. It is a native of North America, and more particularly of South Carolina, where it is not uncommon in muddy and ſwampy places, living generally under water, but ſometimes appearing on dry land. It has a kind of ſqueaking or ſinging voice; hence it was diſtinguiſhed by the name of ſiren. This curious animal was firſt diſcovered and deſcribed by Dr. Garden, who reſided many years in Carolina, and who gave the utmoſt attention to the ſcience of natural hiſtory, which he enriched by many highly intereſting obſervations, and by the diſcovery of many new facts. The doctor communicated ſpecimens of the ſiren to Linnæus, with particulars relative to its hiſtory and manners. The great Swediſh naturaliſt, in his letter to Dr. Garden on this ſubject, declares that nothing had ever exerciſed his thoughts ſo much, nor was there any thing he ſo much deſired to know, as the real nature of ſo extraordinary an animal. Mr. Hunter has given an anatomical deſcription of the ſiren in the 56th vol. of the Philoſophical Tranſactions, to which the reader is referred.

The ſiren, if thrown on the ground with any degree of violence, will ſometimes break in two or three pieces; and in this particular it reſembles the Anguis fragilis, or ſlow-worm. It may alſo be obſerved, that though in ſome reſpects it reſembles the larva of the lizard, yet no lizard, of which it may be ſuppoſed the larva, has ever yet been diſcovered in thoſe parts of Carolina where it is moſt frequent. The ſpecies to which it ſeems moſt allied is the Lacerta *teguixin* of Linnæus, which is a native of South America.

ANGUINE; Four-footed ſiren, with eel-ſhaped body, and ramified branchiæ. This has been denominated the Proteus anguinus by ſome naturaliſts, and by others the Auſtrian ſiren. This animal is found in a very ſingular ſituation, being an inhabitant of the celebrated romantic lake Zirknitz, in the duchy of Carniola, in Auſtria. From this lake the water regularly retires during the ſummer, by numerous ſubterraneous outlets at the bottom; leaving the ground dry, and fit for paſture, as well as for various kinds of hunting, and other amuſements: but in the month of October it again returns with great force, ſpringing out of the paſſages before mentioned, from a vaſt depth, till the lake is completely filled. It is ſituated in a valley, ſurrounded by rocky and woody mountains, in which are vaſt caverns, and it is principally ſupplied by eight rivulets running into it from the adjoining mountainous region. See Phil. Tranſ. vol. xvi.

This ſpecies of ſiren is extremely rare, and is found in the ſpring, and towards the decline of ſummer, in ſome particular parts of the above-mentioned lake, and meaſures from ten to twelve or thirteen inches in length, and about three quarters of an inch in diameter. It is entirely of a pale roſe-colour, or even nearly white, except the three pair of ramified branchial fins on each ſide the neck, which are of a bright red or carmine-colour. Its general ſhape is that of an eel; the body being cylindrical till towards the end of the tail, where it becomes flat, and is attenuated, both above and below, into a kind of fatty fin, ſcarcely diſtinguiſhable from the reſt of the tail; the ſkin is very ſmooth and even; the head is of a ſomewhat depreſſed form, with a lengthened, obtuſe, and widiſh ſnout, and it has no external eyes; the mouth is moderately wide, and furniſhed with a row of very minute teeth; the legs are three quarters of an inch long, and the feet of the fore-legs are furniſhed with three toes, without claws; the feet of the hind-legs have only two toes. The motions of this animal, when taken out of the water, are, in general, extremely ſlow and languid; as is alſo the caſe, when kept in a veſſel of water; but in its native lake, it is ſometimes obſerved to ſwim briſkly, waving its body in a ſerpentine direction, not unlike that of a leech. The Anguine ſiren is figured and very accurately deſcribed by Laurenti, in his work entitled "Specimen Medicum, exhibens Synopſin Reptilium." The real nature of the animal is not completely aſcertained; ſome imagining it to be the larva of ſome ſpecies of lizard, while others contend that it is a perfect animal *ſui generis.* It is evidently of a predacious nature, feeding on the ſmaller kind of aquatic animals; ſince one of them, which was kept alive in a veſſel of water, was obſerved to diſcharge from its ſtomach ſeveral ſmall ſhells of the genus Helix; and in the ſtomach of one, which was diſſected, were found the head and bones of a ſmall fiſh. Its voice is a ſtrong hiſs, much louder than might be expected from the ſize of the animal.

Dr. Schreibers, who has moſt diligently inveſtigated the nature and anatomy of this animal, ſays, "there can be no doubt that it bears a great affinity to the S. lacertina, having both gills and lungs; and therefore it leaves us in equal uncertainty as to its being a perfect animal in itſelf, or the larva of another animal. It is, however, remarkable, that notwithſtanding the moſt careful reſearches during many years, and the frequent fiſhing which takes place in the lakes and caverns of the neighbouring country, at all ſeaſons of the year, no animal has hitherto been found of which it can poſſibly be ſuppoſed the larva."

Pisciformis; Ferruginous-brown ſiren, ſpotted with black, with finely ramified branchiæ, tetradactylous fore and pentadactylous hind-feet. This animal, in the Naturaliſt's Miſcellany, is denominated Gyrinus Mexicanus, or Mexican tadpole. According to the deſcription given in that work, it is a native of Mexico, and, if only the larva of ſome large American lizard, is ſcarcely a leſs ſingular and curious animal than the ſiren. In its general appearance it bears ſome reſemblance to the larva of the Rana paradoxa, but is furniſhed with gills, opening externally in the manner of a fiſh; the openings are very large, and the external flap is continued from the ſides of the head acroſs the throat beneath, ſo as completely to inſulate the head from the breaſt; the gills themſelves conſiſt of four ſemicircular bony or cartilaginous arches, which are denticulated or ſerrated on their internal or concave part, like thoſe of fiſhes; on the opercula, or external flaps, are ſituated three very large and elegant branchial fins, or ramified parts, divided and ſubdivided into a vaſt number of ſlender or capillary proceſſes. In theſe particulars it reſembles the S. lacertina, except that in the latter animal the external opening to the gills is very ſmall; the mouth is furniſhed in front with a row of extremely minute teeth; the tongue is large, ſmooth, and rounded at the tip; the rictus, or gape, when the mouth is cloſed, appears conſiderably wider than it really is, owing to a lateral ſulcus proceeding from each corner to ſome diſtance; the feet are entirely deſtitute of webs, and they are furniſhed with rather weak claws; the front feet have four toes, and thoſe behind five. Independently of the general colour of the animal, the whole ſkin, when minutely examined, appears to be ſcattered over with very minute white ſpecks, reſembling thoſe on the ſurface of the S. lacertina. The ſides of the body are marked by ſeveral ſtrong rugæ or furrows, and an impreſſed lateral line or ſulcus is continued from the gills to the tail.

Siren is alſo a name given by Mouffet, and other authors, to a ſpecies of bee; of which they diſtinguiſh two kinds, a larger and a ſmaller. Theſe differ greatly from the common bee, in that they live ſolitary, and never unite into ſwarms, or build neſts, or make combs.

SIRET, in *Geography*, a town of the province of Bukovina; 85 miles N.W. of Jaſſi.—Alſo, a river of Moldavia, which runs into the Danube; 4 miles S. of Galacz.

SIREX, or *Tailed Waſp*, in *Entomology*, a genus of inſects of the order Hymenoptera, of which the generic character is, Mouth with a thick, horny, truncate, ſhort, denticulate mandible; four feelers, the hind ones longer, and thicker upwards; antennæ filiform, of more than twenty equal articulations; the ſting is exſerted, ſerrate and ſtiff; the abdomen is ſeſſile, terminating in a point; wings lanceolate, incumbent, the lower ones ſhorter.

The larvæ of this genus are ſix-footed, ſoft, cylindrical; the head rounded; they perforate wood, and frequently eat their way into the bowels of other inſects, and their larvæ, living upon them till they have utterly conſumed their entrails; the pupa is folliculate: the perfect inſect lives on the nectar of flowers. There are about twenty-ſix

Species.

* Gigas. The abdomen of this ſpecies is yellow at the baſe and tip; the body is black-blue. This is the largeſt ſpecies in the whole genus: it ſurpaſſes a hornet in ſize, and is principally obſerved in the neighbourhood of pines and other cone-bearing trees: it is of a black colour, with the eyes, the baſe, and lower half of the abdomen, of a bright orange-yellow; the thorax is villoſe, and the wings of a tranſparent yellowiſh-brown; the ſting, or terminal tube, is very conſpicuous. The larva, which meaſures about an inch and a quarter in length, is of a yellowiſh-white colour, and inhabits decayed firs and pines; at firſt view it bears ſome reſemblance to the larvæ of the beetle tribe, but is thinner in proportion, and furniſhed, at the tip of the abdomen, with a ſhort black ſpine or proceſs. It changes to a chryſalis in the month of July; firſt enveloping itſelf in a ſlight ſilken

web of a whitiſh colour. The chryſalis is of a lengthened ſhape, with the antennæ, legs, and terminal tube or proceſs, very diſtinctly characterized. If the change to chryſalis takes place, as it ſometimes does, in ſummer, the fly proceeds from it in the ſpace of about three weeks; but if at the cloſe of autumn, the animal continues a chryſalis the whole winter, emerging in the following ſpring. The male inſect is conſiderably ſmaller than the female, and may be farther diſtinguiſhed by the want of the caudal tube or proceſs, ſo conſpicuous in the female inſect: the tip of the abdomen is alſo of a black colour. The eggs, which are depoſited by the female in the decayed parts of the trees already mentioned, are very ſmall, and of a lengthened oval ſhape, with pointed extremities.

Psyllius. Abdomen yellow at the baſe and before the tip; the body is black. It inhabits different European countries, and is half the ſize of the laſt. The antennæ and legs are yellow, and the thighs black; the head is black, with a yellow ſpot on each ſide, behind the eyes; certain ſegments of the abdomen yellow.

Columba. This is an American ſpecies, and is diſtinguiſhed by its black body, marked by teſtaceous bands. The ſpecific character is as follows: thorax villous, ferruginous; abdomen black, the ſides are ſpotted with yellow; the antennæ are ſhort and black, ferruginous at the baſe; the abdomen beneath is black, with a yellow ſtreak; the projection is ſhort, acute, ſerrate, yellow tipped with black; the legs are yellow; hind-thighs black.

Magus. Black, thorax villous; tip of the antennæ, lateral ſpots on the abdomen, ſhanks, and baſe of the tarſi, are white. It is of the ſize of the S. gigas, and is found in many parts of Saxony. The abdomen beneath is white in the middle; the wings are duſky.

Nigricornis. Thorax villous, blueiſh-black; abdomen ferruginous, blue at the baſe. It is found in North America. The head is ſhining blue-black; the antennæ are black; the legs are piceous; thighs yellow; ſting pitchy.

Flavicornis. Thorax villous, black, immaculate; four bands on the abdomen, antennæ, and legs, yellow. It is found at Labrador, in America. The head is black; the upper part of ſome of the ſegments is yellow; the appendage ſerrate, yellow; the ſting is black.

Fuscicornis. Thorax villous, black; abdomen with eight yellow bands; the antennæ are black; the legs are yellow. This, which is of the ſize of the gigas, inhabits Saxony. The wings are ſubteſtaceous; the ſting is black, with a yellow ſheath; the horn of the abdomen is ſubulate, yellow tipt with black; the thighs are black.

* Spectrum. The abdomen of this ſpecies is black; the thorax is villous, with a yellow ſtripe before the wings. It is found in this country, and in many other parts of Europe. The antennæ are black or yellow, and the legs are yellow.

* Juvencus. The abdomen is blueiſh-black; the thorax villous, immaculate. This alſo is a native of England and other European countries. The antennæ are black or yellow; the legs are yellow.

Phantoma. Abdomen above yellow, with black belts; the head and legs are yellow. It inhabits Germany. The mouth is black; the thorax yellowiſh before, beneath black; the abdomen beneath is black.

Cyanus. This is of a ſhining blue colour; the legs are yellow. It inhabits North America. The antennæ are black; the thorax ſubvillous; the wings are hyaline.

Albicornis. Black; head with a white ſpot on each ſide; the antennæ are white in the middle. It is a native of North America. The antennæ are black at the tip; the abdomen with a white dot on each ſide on the laſt ſegment but one; the legs are black; the ſhanks and ends of the tarſi are white.

Nigrita. This is of a black-blue, immaculate; the hind-legs are compreſſed. It is a native of Saxony, and is of the ſame ſize as the S. mariſcus, hereafter to be noticed.

* Camelus. The abdomen is black, the ſides ſpotted with white; the thorax ſmooth. This is found in England and other European countries.

Emarginatus. Black; thorax emarginate before, and pale at the ſides; the fore-legs are rufous. It inhabits Germany. The antennæ are black; the head is black, with a pale ſpot on each ſide: the ſides of the thorax are ſlightly ſerrate. The four front legs are rufous; the ſhanks are tipt with black; the hind ones are black; the thighs rufous.

Dromedarius. Abdomen black, rufous in the middle, with a white dot on each ſide. The ſhanks are pale at the baſe. It is chiefly found at Kiel, and reſembles the S. camelus. The head is black, with two white lines; the thorax is black, with a white dot before the wings; ſome of the ſegments of the abdomen are black, ſome rufous, one black, with a white ſpot on each ſide, and one is altogether black.

Pacca. Abdomen black, two of the ſegments are rufous, the reſt dotted with white. This alſo is found at Kiel, and is the ſize of the S. camelus. The antennæ are black, a little thicker towards the tip; the thorax is villous and black, with two minute white ſpots on the fore margin; the horn of the abdomen yellowiſh, ſting rufous; legs compreſſed, black.

Similis. Black; firſt ſegment of the abdomen at the baſe and ſecond rufous, the reſt with five yellow ſpots. It inhabits the Cape of Good Hope. The head is black; the orbits yellow; antennæ ferruginous; the baſe and tip black; the thorax black, with a yellow dot on each ſide; the legs are rufous, the thighs black; the tail is pointed, without any projection.

Vespertilio. Black; abdomen ferruginous, the baſe is black. This is a ſmall inſect, and is found in divers parts of Germany. The antennæ are black, with a whitiſh ring; the tail is black beneath, without the appendage; the upper wings are white, with a broad brown patch before the tip, and white marginal dots; the legs are black, tip of the thighs and baſe of the ſhanks white.

Mariscus. Of this ſpecies the abdomen is teſtaceous, the two laſt ſegments are black; the thorax villous. This is found in divers parts of Europe. Antennæ yellow; head with a yellow callous dot behind the eyes; the abdomen beneath is black, ſpotted with yellow: it has no ſting.

Troglodyta. Smooth, black; abdomen with ſeven yellow dots, and two bands. It inhabits Saxony. The legs are yellow; the thighs black.

Noctilia. This is of a black-blue colour; the antennæ are black; the thorax is villous; the abdomen teſtaceous in the middle. It inhabits ſeveral parts of Germany, and is about the ſize of the S. mariſcus. Thorax blue; abdomen blue at the baſe and tip; wings yellowiſh; legs yellow; hind ones compreſſed, black, the thighs yellow.

Compressa. Black; abdomen compreſſed, ferruginous; the firſt and laſt ſegments are black. It inhabits Barbary, and is very ſmall. Legs white; thighs black; hind ones black; the ſhanks are compreſſed, black, with two yellow dots, and three bands.

* Pygmæus. Abdomen compreſſed, black, with two yellow dots and three bands. It is a native of this country, and of other parts of Europe. This is one of the ſmalleſt of the European ſpecies, being, according to Linnæus, about

the ſize of a gnat, with a black abdomen, marked by three yellow bands, the middle of which is interrupted. It is found in Sweden.

Macilentus. Black; abdomen compreſſed, yellow at the ſides. It inhabits Barbary, and reſembles the next. The head is black, with two yellow dots between the eyes; the thorax black, with a yellow dot, and a larger one beneath; the abdomen is yellow at the ſides, and projecting into two bands on the back; the wings are hyaline; the rib black beyond the middle; the legs are black; the fore-thighs are yellowiſh.

* Tabidus. Black; ſides of the abdomen dotted with yellow; fore-ſhanks teſtaceous. It inhabits England, and a ſpecimen is in ſir Joſeph Banks's muſeum.

SIRGAI-SOUSAI-PO, in *Geography*, a town of Chineſe Tartary. N. lat. 42° 15′. E. long. 117° 50′.

SIRGIAN, Serjan, or *Kerman*, the ancient *Carmana*, a city of Perſia, which at a former period rivalled the proudeſt cities of the empire; and its ſituation, in the direct road from the northern provinces of Perſia and Bucharia to Gombroon, then the great emporium of the India trade, contributed to the increaſe of its opulence and proſperity. It has, however, ſuffered much from deſtructive wars, domeſtic and foreign, and from the plunder of an exaſperated and licentious army. After having been courageouſly defended, in 1794, by Lutf Ali Khan, it was betrayed into the hands of his rival Aga Mohamed Khan, by Nujuf Kooly Khan, one of his treacherous adherents. The city was abandoned for nearly three months to the rapacity of the ſoldiers, the walls and public buildings were levelled with the ground, great numbers of the inhabitants were put to death, and 30,000 of them were exiled into the diſtant provinces of the empire: nor will it probably ever recover from the effects of this dreadful calamity. The preſent fortifications incloſe but a ſmall portion of the ancient city, which is quite deſerted, and in a moſt ruinous condition. It is ſituated on the weſtern ſide of an extenſive plain, ſo cloſe to the mountains as to be completely commanded by two of them. The walls are high, and built of mud, with 19 or 20 poſitions in each face, and a dry ditch, 20 yards wide and 10 deep. It has four gates, and the ark or citadel, where the governor reſides, is on the S. ſide of the fort. Its preſent population is not more than 20,000 ſouls, of which ſome few are Guebres; there are alſo Armenians, Jews, and Hindoos in the place. Its trade is ſtill very conſiderable; and it is celebrated for its manufacture of ſhawls, match-locks, and carpets, which are chiefly exported to Khoraſſan and the northern provinces, and returned in drugs, ſkins from Bockhares, furs, ſilk, ſteel, and copper. Theſe articles, as well as piſtachio nuts, carpets, roſe-buds for preſerves, and bullion, are ſent to India, whence are imported, tin, lead, iron, chintz, wrought ſilk, ſpices, indigo, maſtic, gold brocade, china and glaſs-ware, broad-cloth, hard-ware, &c. The bazar is well ſupplied with articles of every deſcription, and in one part neatly arched with a fine blue ſtone, procured in the adjoining mountains. There are nine caravanſeras within the walls, and many inferior ones both within and without. N. lat. 29° 30′. E. long. 56° 50′.

SIRGOULIN, a town of Chineſe Tartary. N. lat. 41° 53′. E. long. 119° 14′.

SIRGUNE, a river of Pruſſia, which runs into the Friſch Haff, below Elbing.

SIRHIND, a circar of Hindooſtan, between the ſoubah of Delhi and Lahore, bounded on the N. by Thibet, on the E. by the Jumnah, which ſeparates it from Schaurunpour, on the S. by the circar of Nardeck, and on the W. by Moultan and the province of Jallindar.—Alſo, a town of Hindooſtan, and capital of the above-mentioned circar, N. of Delhi, ſuppoſed by ſome to be built on the ſpot where the battle was fought between Alexander and Porus. Juſtinian is ſaid to have had ſilk from hence: it is an ancient city, but, like moſt of the Indian cities, has greatly declined: between it and Delhi are extenſive plains, within which are ſituated the towns of Panniput and Carnawl, famous for great battles, both in ancient and modern times; 140 miles S.E. of Lahore. N. lat. 30° 41′ 30″. E. long. 76° 6′.

SIRHUD, literally meaning a boundary, and metaphorically applied to a cold region, a diſtrict of Perſia, comprehending moſt of the mountainous part of the province of Fars, extending from the latitude of Kazaroon to that of the town of Yezdekhaſt, ſituated on the bed of what appears to have been formerly a river, which ſeparates this province from Irak. The plains which here interſect the mountains ſeldom exceed eight or ten miles in breadth, but vary in length from 15 to 100. They are in general fertile, and afford abundance of paſturage; neither are they ſo deficient in water as ſome have ſuppoſed. It is the want of population and of encouragement to induſtry that retards their improvement.

SIRI, among the Romans, were ſubterranean caves or vaults, in which wheat could be kept ſound and freſh for fifty years.

Siri, Vittorio, in *Biography*, a writer in politics and hiſtory, was born at Parma about the year 1607: he was educated for the ſtudy of theology, and took the habit of the Benedictine order, in the monaſtery of St. John, and there began to publiſh a work entitled "Mercurio Politico," by which he acquired ſome temporary celebrity. Fifteen volumes of this work appeared ſucceſſively, containing an account of the public events from 1635 to 1655. After this he added to it "Memoriæ Reconditæ," in eight vols. which going back to 1601 come to 1640. The author not only records facts, but endeavours to inveſtigate cauſes in the ſecret negociations of cabinets, and to give the documents confirming his narrative. Of theſe pieces, a great number is to be found in his publications, communicated by popes' nuncios and the ambaſſadors of different crowned heads, and eſpecially by the miniſters of Louis XIV. Through the influence of cardinal Mazarin, he was invited by that monarch to Paris, and preſented to a ſecular abbey, on which occaſion he quitted his religious habit for that of an eccleſiaſtic. He aſſumed to himſelf the title of counſellor, almoner, and hiſtoriographer to his moſt Chriſtian majeſty, and he ſpent all the latter years of his life at Paris, where he died in the year 1685, at the age of 78. He is characterized by biographers as a man without any fixed principles, who had a venal pen, which was always ready to juſtify and defend any cauſe, provided he was liberally paid for his ſervices; yet the opportunities he poſſeſſed of gaining information from authentic ſources, and the number of original documents publiſhed by him, have given a marked value to his works as materials for the hiſtory of his time. The circumſtances of his being a foreigner, and writing in Italian voluminous publications little read in France, are ſaid by Le Clerc to have induced him to ſpeak more freely of Louis XIII., his brother and miniſters, than the French writers have done. The firſt four volumes of his "Memoriæ Reconditæ" are extremely rare. A tranſlation into the French language, of the moſt important parts of all his works, has been publiſhed in ſeveral volumes by M. Requier. Siri is ſaid alſo to have written under a feigned name ſome pieces reſpecting the war of Montſerrat.

Siri, in *Geography*, a mountain of Thibet; 36 miles N.E. of Taringaſong.

Siri, or *Dſiri*, a town of Thibet; 45 miles E. of Taringaſong.

SIRIA, or Sirja, a town of Syria, in the pachalic of Aleppo; 70 miles S.E. of Aleppo.

SIRIAGULLY, a town of Mocaumpour; 20 miles S.S.W. of Mocaumpour.

SIRIAN, a ſea-port town of Pegu, on the river Appoo, and whilſt it remained in poſſeſſion of the Portugueſe, a place of great trade. Before their time it had a king of its own: it is now frequented by French, Engliſh, and Dutch; 72 miles S. of Pegu. N. lat. 16° 54′. E. long. 96° 50′.

SIRIASIS, in *Medicine*, from σιϱος, *a cavity*, a diſeaſe of children, ſo named by the older writers, in conſequence of an accompanying depreſſion of the fontanelle, but which in fact appears to have been an inflammation of the brain and its membranes; and accordingly Dr. Cullen ranks it as ſynonimous with *phrenitis*. It is very indiſtinctly deſcribed, and in ſome reſpects reſembles hydrocephalus. Aëtius, indeed, expreſsly aſſerts that it is an inflammation of the brain and its membranes; but the only ſymptoms which he enumerates, are hollowneſs of the ſinciput and of the eyes, ardent fever, paleneſs, dry ſkin, and total loſs of appetite. See Aëtius, Tetrab. i. Serm. iv. cap. 13. Foreſt. Obſ. Med. lib. xxviii. cap. 82. Sennert. Pract. lib. i. part i. cap. 20.

SIRIBOA, in *Botany*, Rumph. Amboin. v. 5. 340. t. 117. *Piper Siriboa*, Linn. Sp. Pl. 51, is a kind of long pepper, reckoned one of the kinds of Betle, and uſed for chewing with the *Areca*, or Betle nut, on account of its gratefully aromatic, and not too pungent, flavour. See Piper.

SIRICA, in *Geography*, a town of Tripoli; 120 miles S. of Meſurada.

SIRICIUS, *Pope*, in *Biography*, was a native of Rome, and ſucceeded to the pontifical throne in 384. There are extant ſeveral letters of this pope, which are accounted his firſt decretals. In his firſt epiſtle, in anſwer to ſome queſtions propoſed by Himerius, biſhop of Tarragona, are many curious particulars of the eccleſiaſtical diſcipline obſerved at that period. He was a warm oppoſer of the Priſcillianiſts and Jovinians, and in one of his letters relative to the latter, an example appears of the ancient manner in which the apoſtolic ſee paſſed its judgments: Siricius acquainted the church of Milan that he had condemned Jovinian and his followers, with the conſent and advice of the prieſts, deacons, and all the clergy. In another of his letters, a cogent teſtimony is given of the reverence paid by the ancient popes to the deciſion of councils: it is addreſſed to ſome biſhops reſpecting the hereſy of one Bonoſus, who was accuſed of aſſerting that the Virgin Mary had children after the birth of Chriſt. The pontiff replies, that the ſynod of Capua having ordained that the prelates in the vicinity of Bonoſus ſhould take cognizance of his cauſe, it did not belong to him to enter into the diſpute. Siricius had the ſatisfaction of ſeeing ended the long continued ſchiſm of Antioch, the biſhop of which, Flavianus, had occupied the ſee for a number of years, without being acknowledged by the Egyptian biſhops. Through the mediation of John Chryſoſtom, a reconciliation was effected, and Flavianus was acknowledged by the pope, who died ſoon after in 398, leaving behind him a very reſpectable character.

SIRICON Plumbi, a name given by ſome chemical writers to calcined lead, or the grey powder made of lead by a ſlight calcination in an open fire.

SIRINAGUR, Srinagor, or *Caſhmere*, in *Geography*. See Cashmere.

Sirinagur, or *Srinagur*, a town of Thibet, capital of a diſtrict in Alucknundra, or Alacananda, a branch of the Ganges, which has its ſource in the ſnowy mountains of Thibet, the poſition of which, according to Capt. John Guthrie, who viſited it in 1789, is 85 miles from Coadwar Gaut, through the hills, and 60 coſſes from Hurdwar, up the Ganges to the E.N.E., aſcertained by a compaſs and perambulator. Mr. Daniel, who viſited it in the ſame year, gives the ſame idea of its geographical poſition. It is ſituated in an exceeding deep and very narrow valley, formed by mount Sewalick, the northern boundary of Hindooſtan on one ſide, and the vaſt ridge of ſnowy mountains of Himmaleh, or Imaus, on the other. Mr. Daniel was much ſtruck with the magnificence of the ſcenery of this valley, in which the thermometer roſe, in the ſhade, to 100°, though in croſſing the mountain of Sewalick, it ſtood at 58½°. We ſhall here ſubjoin ſome further particulars on this ſubject, with which we are furniſhed by a narrative of a ſurvey for the purpoſe of diſcovering the ſources of the Ganges, by Capt. Raper, communicated to the ſociety at Calcutta. This ſurvey was ordered by the ſupreme government of Bengal in 1807, and at the recommendation of Lieut. Col. Colebrooke, executed by Lieut. Webb, accompanied by Capt. Raper and Capt. Hearſay. The party commenced their tour at Hurdwar, an inconſiderable town of one ſtreet, in N. lat. 29° 57′ 9″. E. long. 78° 8′ 30″, April 1ſt, 1808. On the 13th of May they arrived at Srinagur, in N. lat. 30° 10′ 52″. E. long. 78° 43′. The town is ſituated on the S. bank of the Alacananda, in the centre of a valley, which is about four miles in length, running nearly in the direction of E.N.E. to W.S.W., and about two miles in its greateſt breadth. It extends along the banks of the river, and forms, in ſhape, a ſmall ſegment of a circle, of which the ſtream conſtitutes the chord. The principal ſtreet runs through the city, about four furlongs in length, and contains the grand bazar. The houſes are in general two ſtories high, conſtructed of large ſtones, with a ſhelving ſlated roof of ſhingles. The lower apartments are allotted for ſhops and merchandize, the upper for the accommodation of the families. The rigid uniformity of the buildings, both in ſtructure and materials, ſhews what little advancement has been made in architecture, at the ſame time that it detracts from the beauty of the place. A narrow projecting verandah, or balcony, forms the only apparent difference in the houſes of the higher claſs of inhabitants; and ſuch a ſyſtem of equality prevails, that one might ſuppoſe it the effect of deſign, or of a cautious fear to manifeſt an increaſe of wealth, by an oſtentatious diſplay in their outward appearance. Even thoſe of the two chiefs by no means convey the idea of manſions appropriated to the reſidence of men to whom was committed the government of a province. When this capital was viſited by Col. Hardwicke, in the year 1796, it was under the government of a raja, to whom it had hereditarily deſcended through many generations, and might then be ſuppoſed to be in its moſt flouriſhing ſtate; yet its appearance did not indicate opulence or ſplendour; but ſince that period, many natural and fortuitous cauſes have combined to reduce it to a lower ſtate of poverty and inſignificance. The encroachments annually made by the Alacananda, on the houſes contiguous to the river, the earthquake of 1803, which ſhook every building from its foundation, and the Gurc'hali invaſion at the cloſe of the ſame year, devolved ſuch an accumulation of evils on this devoted capital, that one might have inclined to conclude that it would not ſurvive its native princes,

princes. Every houſe and every ſtreet, not excepting the palace of the raja, exhibited marks of dilapidation. Many of the inhabitants expreſſed their ſorrow and regret on account of the events that had occurred, and ſpoke of their former ſovereign with great tokens of feeling. Under its Gurc'hali rulers the city is not likely to recover from this forlorn condition; for all claſſes of people complain much of the peculation of the chiefs, and of the injuſtice, with the want of method, that attends all their proceedings. The inhabitants are compoſed chiefly of the deſcendants of emigrants from the Dooab, Rohilcund, and Audh. The Hindoos form the greateſt proportion: the number of Muſſulman families not exceeding ſixty or ſeventy. Moſt of theſe are petty ſhopkeepers, who, to gain a ſcanty ſubſiſtence, are forced to enter into various ſpeculations; and a piece of ſilk or a ſer of onions may be procured at the ſame ſhop. The principal perſons are the agents of great banking houſes at Najibabad and in the Dooab, who are employed in the ſale and exchange of merchandize and coins. They reſide here only eight months in the year; quitting the hills, and returning to their houſes, at the commencement of the rainy ſeaſon. The traffic in ſilver and ſpecie forms one of the moſt profitable branches of commerce, and is carried on to a conſiderable amount. Bullion and coins are imported, for the purpoſe of being converted into temaſhas, the currency of the hills; and as a conſtant coinage of them is kept up at the mint, the ſupplies are furniſhed by the Serrafs, who receive a premium, agreeable to the quality of the ſilver, amounting to one and a half, or two *per cent.* on the Farrakabad or Bareli rupee. The temaſha is a ſmall uneven ſilver coin, four of which paſs for the nominal rupee of the hills; and five for the Farrakabad or Bareli. Spaniſh dollars alſo find their way hither, and are converted into the ſame currency. The inferior coin is a ſmall piece, ten tacas of which are equal to one temaſha.

The other articles of ſpeculation conſiſt in the produce of the hills, and imports from Bootan. The former are *bhang* (hemp); a coarſe cloth, or ſort of canvas, manufactured from it, called *bhangela;* lead, copper, drugs, gums, wool, and a ſpecies of flannel made from it called *panc'hi;* from Bootan are received chaurs or cow-tails, muſk in pods, ſaffron, borax, ſalt, drugs of different kinds, and a few ſhawls, which come by that route from Caſhmere. Among the drugs is one called nirbiſi, or zedoary. Hawks are alſo brought down from the hills. In exchange for the above, the following articles are ſupplied from the low countries. Coarſe cotton and woollen cloths, ſilk, ſpices, Lahore ſalt, ſugar and tobacco. On all theſe goods a greater or leſs duty is levied at Sirinagur, amounting, on an average, to one ana in the rupee, or about eight and a third *per cent.*; and additional duties are collected at different poſts, in their tranſit through the country.

The territories which formerly belonged to the raja of Sirinagur, are now divided into 84 perganahs, included in three pat'his, or diviſions, over each of which is appointed a military governor, who has the ſame juriſdiction in his own diſtrict.

In the year 1803 an army of 8000 or 10,000 men was ſent from Napal, to execute a project which had been long formed at the court of Napal, *viz.* that of invading the territories of the raja of Sirinagur, and extending their poſſeſſions to Caſhmere. The troops of the raja amounted to 15,000 or 20,000 men, principally mercenaries, who endeavoured to ſhun an engagement: the death of their chief ſecured the conqueſt of the whole country to the Gurc'halis.

On taking a view of Sirinagur from a height, it has the appearance of a double valley; one ſituated on a level with the river, the other on its banks, elevated about forty or fifty feet, and extending along the baſe of the mountain. The lower one, in which the city ſtands, has apparently been formed by the receding of the Alacananda from the ſouth ſhore; and although the period be too remote to aſcertain the fact, the appearance of the ridge or bank, marking the concavity, would incline one to ſuppoſe that ſuch has been the caſe; and that, in its preſent progreſſive inclination, it is gradually returning to its former channel. From the bottom of the upper valley, to the city, is a ſpace of three or four furlongs, laid out in ſmall fields and incloſures, with a few mango trees, thinly ſcattered among them. Oppoſite to the city, the Alacananda divides into two or three ſtreams, which reunite about one mile below. On one of the ſmall iſlands are the ruins of buildings, which were formerly connected with the city. The aſpect of the ſurrounding mountains is very barren; here and there a ſolitary tree may be ſeen; but the general features betray a rocky and unfriendly ſoil, and the little vegetation that is produced on them is ſoon parched up and dried. On the oppoſite ſide of the river, ſeveral hamlets are ſeen, ſituated along the foot of the hills, with which a communication is open, by a jhula to the W. and a ferry boat to the E. of the city. One of the largeſt of theſe villages is called Rani Hat't, containing a temple ſacred to raja Iſwara, at whoſe ſhrine ſome rites are performed, in imitation of the myſteries obſerved in the temple of the Cyprian goddeſs. It is inhabited chiefly by dancing women; and the ceremony of initiation to this ſociety conſiſts in anointing the head with oil, taken from the lamp placed before the altar; by which act they make a formal abjuration of their parents and kindred, devoting their future lives to proſtitution. A ſhort diſtance beyond it is a Mat'h or fane of Raſſea Devi, the god of love; whoſe ſhafts, if we may believe the reports and complaints of his numerous votaries, are tainted with a fatal and pernicious poiſon: indeed, his wounds appear to be ſo generally diffuſed, that four-fifths of the inhabitants are ſuppoſed to labour under the effects of them, and the calamity is heightened by their ignorance of proper remedies to check their progreſs. Aſiatic Reſearches, vol. xi.

Sirinagur, a town of Bengal; 20 miles N.N.E. of Calcutta. N. lat. 23° 7′. E. long. 88° 48′.

SIRIS, Siro, or *Sinno*, in *Ancient Geography*, a river of Italy, near the Acinis, in Lucania. See Sinno.

Siris, a very ancient town of Italy, in Lucania, ſaid by Strabo to have been founded by Trojans, and eminent for its college of prieſts ſkilled in cabaliſtic lore. It was ſituated at the mouth of a river of the ſame name, now called *Sinno* (which ſee), and became a dependance of Heraclea, to which the principal inhabitants of Siris were obliged to remove. When the Ionians took poſſeſſion of this city, they changed its name into that of Policram. In proceſs of time, the Tarentines drove the inhabitants from Siris, and having ſent a colony into this country, they built Heraclea at a ſmall diſtance from Siris. Strabo diſtinguiſhes theſe two towns; but Pliny (l. iii. c. 10.) ſays that they were the ſame under different names. The adjacent country was called Siritis, or Sirentis.—Alſo, a town of Pæonia, in Thrace.

SIRISHEK, in *Geography*, a town of Perſia, in Khoraſſan; 30 miles S.S.W. of Herat.

SIRIUM, in *Botany*. See Santalum.

SIRIUS, σειριος, in *Aſtronomy*, the *Dog-ſtar*, a very bright ſtar of the firſt magnitude, in the mouth of the conſtellation Canis Major, or the Great Dog.

This, indeed, is the brighteſt of all the ſtars in our firmament, and, therefore, probably, ſays Dr. Maſkelyne, the late aſtronomer royal, in a paper recommending the diſcovery of its parallax, Phil. Tranſ. vol. li. p. 889, the neareſt to us of them all. Some, however, ſuppoſe Arcturus to be the neareſt.

The Arabs call it *Aſchere, Elſchecre, Scera;* the Greeks, *Sirius;* and the Latins, *Canicula,* or *Canis candens.* See Canicula.

Sirius, in *Geography*, an iſland in the South Pacific ocean, diſcovered and ſo called by lieutenant Ball, in 1790; it is about 18 miles in circumference. S. lat. 10° 52′. E. long. 162° 30′.

SIRMAN, Mad., in *Biography*, a celebrated performer on the violin, who had her muſical education in a conſervatorio at Venice. Her maiden name was Maddalena Lombardini. She was a favourite élève of Tartini, and it was for her that he drew up his little tract on the uſe of the bow on the violin, in the form of a letter, "Arte dell' Arco."

After quitting the conſervatorio, ſhe married a German of the name of Sirman, and came to England in 1773; when her performance of Tartini's compoſitions on the violin was juſtly and univerſally admired. But in the operas of "Sofoniſba" by Vento, and the "Cid" by Sacchini, ſhe unadviſedly undertook the ſecond woman's part on the ſtage, as a ſinger; but having been firſt woman ſo long upon the violin, ſhe degraded herſelf by aſſuming a character, in which, though not deficient in voice or taſte, ſhe had no claim to ſuperiority.

SIRMARKS, in *Ship-Building*, the different ſtations marked on the moulds where the reſpective bevellings are to be applied, as the lower ſirmark, floor-ſirmark, &c.

SIRMIONE, in *Geography*, a peninſula of Italy, about ſeven miles from the Lago di Garda, anciently celebrated under the name of Benanus, and always eſteemed one of the grand ornaments of Italy. From *Peſchiera* (which ſee), Sirmione appears as an iſland; ſo low and ſo narrow is the bank that unites it to the main land. Its entrance is defended, and indeed totally covered, by an old caſtle, with its battlements and high antique tower in the centre, in the form of a Gothic fortification. The promontory ſpreads behind the town, and riſes into a hill, entirely covered with olives; which hill may be ſaid to have two ſummits, as there is a gentle deſcent between them. On the neareſt is a church and hermitage, now uninhabited and neglected. On the fartheſt, in the midſt of an olive grove, ſtand the walls of an old building, ſaid to be a Roman bath; and near it is a vault, called the grotto of Catullus. The extremity of this promontory is covered with arched ways, towers, and ſubterranean paſſages, ſuppoſed by the inhabitants to be Roman, but bearing, in fact, a ſtrong reſemblance to Gothic ruins. At all events, Catullus undoubtedly inhabited this ſpot, and preferred it, at a certain period, to every other region. He has expreſſed his attachment to it in ſome beautiful lines.

> "Peninſularum Sirmio, inſularumque
> Ocelle, quaſcunque in liquentibus ſtagnis
> Marique vaſto fert uterque Neptunus:
> Quam te libenter, quamque lætus inviſo."
>
> Catull. 32.

He could not, in fact, have choſen a more delightful retreat. In the centre of a magnificent lake, ſurrounded with ſcenery of the greateſt variety and majeſty, apparently ſecluded from the world, yet beholding from his garden the villas of his Veroneſe friends, he might have enjoyed alternately the pleaſures of retirement and ſociety; and daily, without the ſacrifice of all his connexions, which Horace ſeemed inclined to make, in a moment of deſpondency, beheld the grandeur and agitation of the ocean, without its terrors and immenſity. Beſides, the ſoil is fertile, and its ſurface varied; ſometimes ſhelving in a gentle declivity, at other times breaking in craggy magnificence, and thus furniſhing every requiſite for delightful walks and luxurious baths; while the views vary at every ſtep, preſenting rich coaſts or barren mountains, ſometimes confined to the cultivated ſcenes of the neighbouring ſhore, and at other times bewildered and loſt in the windings of the lake, and the receſſes of the Alps. In ſhort, more convenience and more beauty are ſeldom united; and ſuch a peninſula is, as Catullus enthuſiaſtically obſerves, ſcarcely to be matched in all the wide range of the world of waters.

SIRMIUM, or Sirmich, a town of Sclavonia, where the emperor Probus was born and killed. It is now in ruins, though the ſee of a biſhop, founded, it is ſaid, in the reign of Trajan. In the year 270, the emperor Claudius died here of the plague; 40 miles N.W. of Belgrade.

SIRMOND, James, in *Biography*, a theologian of conſiderable note, born at Riom in 1559, was the ſon of a magiſtrate in that city. He was educated at a college of the Jeſuits, which ſociety he entered in 1576. Being ſent to Paris, he taught in a college there, and at the ſame time purſued his ſtudies with ſo much ſucceſs, that he acquired a perfect knowledge of the learned languages, and formed a ſtyle in the latter, which, it is ſaid, has rarely been excelled, either with reſpect to its ſtrength or purity. He obtained ſo high a character for erudition, that he was ſummoned to Rome, in 1590, by Aquaviva, general of the order, to take upon him the office of his ſecretary. This office he held 16 years with high honour, and, in the mean time, he made uſe of all the advantages of the ſituation for the ſtudy of antiquities. He cultivated the acquaintance of all the great men of that period, among whom were Bellarmine, Barberini, and Baronio. To the latter he rendered important ſervices in the compoſition of his Annals, eſpecially by furniſhing him with memorials relating to the Grecian hiſtory, tranſlated into the Latin language. He returned to Paris in 1608, and reſided four years in the houſe of the Jeſuits, during which he edited ſeveral works of antiquity. He alſo entered into the controverſy occaſioned by Richer's famous treatiſe concerning the eccleſiaſtical and civil powers, in which he appeared as a partizan of the court of Rome. In 1612 he was employed in the labour of making a collection of the French councils; but this work did not cauſe him to intermit his publication of ancient writings; and a year ſeldom paſſed without ſending one of them to the preſs, with learned commentaries. He was choſen rector of the Jeſuits' college in Paris, in the year 1617, continuing to occupy himſelf as an editor and writer of original works. Pope Urban VIII. invited Sirmond to Rome, but Lewis XIII. would not conſent to loſe ſo eminent a ſcholar from his capital; and in 1637 he choſe father Sirmond as his confeſſor. In this ſituation he conducted himſelf ſo as to merit the eſteem of the king and his court. He rarely aſked any favours for his relations; but he conferred an important benefit on his native place, by obtaining the revocation of an edict, which had tranſferred the board of finances of Auvergne from Riom to Clermont. When he quitted the court, he continued his literary occupations, which he purſued to a very advanced age. Huet, who, when a very young man, was introduced to Sirmond, then 90 years of age, found him inactive in body, but alert and vigorous with regard to his underſtanding and mental powers. He has deſcribed him as poſſeſſed of uncommon courteſy and elegance of manners, like one who had been long converſant with important public buſineſs.

neſs. He died in 1651, at the age of 92. He was editor chiefly of the authors of the middle ages, the MSS. of which he diſcovered among the libraries at Rome, and other places. Thoſe of his own compoſition were, in a great part, controverſial. One, entitled "Cenſura de ſuburbicariis Regionibus," which related to the ſuburbicarian churches under the juriſdiction of the Roman pontiff, impugned the opinions of Godefroy and Saumaiſe. He had a diſpute with Peter Aurelius reſpecting the ſecond canon of the council of Orange, which was conducted on both ſides with much acrimony. He was attacked with great bitterneſs, on account of a diſſertation which he wrote, to prove that St. Denis the Areopagite was a different perſon from St. Denis of France; but all fair judges of the ſubject admitted the validity of his arguments. He was leſs ſucceſsful in a controverſy reſpecting predeſtination, by which he became involved in hoſtility with the Janſeniſts. He never brought out, at firſt, all he knew on the ſubject, but made a reſerve of ſome arguments for replication. His works were publiſhed collectively at Paris, in five volumes folio, 1696.

SIRNAME. See Surname.

SIROCC, or Sirocco, a ſouth-eaſt wind of Sicily, particularly at Palermo, attended with an uncommon degree of heat, and ſingularly relaxing and oppreſſive in its effects. The blaſt of it is repreſented as reſembling burning ſteam from the mouth of an oven: the whole atmoſphere, during its continuance, ſeems to be in a flame. Its effect is deſcribed by Brydone like that of one of the ſubterranean ſweating ſtoves at Naples; but it was much hotter. In a few minutes, thoſe who are expoſed to it find every fibre relaxed in a moſt inconceivable manner, and the pores opened to ſuch a degree, that they expect immediately to be thrown into a moſt profuſe ſweat. At this time the thermometer, which ſtood in a room only at 73, roſe immediately in the open air to 110, and ſoon after to 112. The air was thick and heavy, but the barometer was little affected, having fallen only about a line. The ſun did not appear during the whole day; otherwiſe the heat, ſays Mr. Brydone, muſt have been inſupportable; and on that ſide that was expoſed to the wind, it could not be borne without difficulty for a few minutes. Upon expoſing pomatum to it, the heat of the wind melted it as if it had been laid before the fire. This wind is more or leſs violent, and of longer or ſhorter duration at different times: however, it ſeldom laſts more than 36 or 40 hours, ſo that the walls of the houſes are not warmed throughout, or elſe it is apprehended that it would be inſupportable. Whilſt it laſts, the people of the country confine themſelves within; their windows and doors are ſhut cloſe, to prevent the external air from entering; and where window-ſhutters are wanting, they hang up wet blankets on the inſide of the window. The ſervants are conſtantly employed in ſprinkling water through all the apartments, in order to preſerve the air in as temperate a ſtate as poſſible; and for this purpoſe, each houſe in the city of Palermo is provided with a fountain. By theſe means the people of faſhion ſuffer very little from this wind, except the ſtrict confinement to which it obliges them. Notwithſtanding the ſcorching heat of the ſirocc, it has never been known to produce any epidemical diſorders, or to do any injury to the health of the people. They feel, indeed, very weak and relaxed after it; but a few hours of the Tramontane, or north wind, which generally ſucceeds it, ſoon braces them up again, and reſtores them to their former ſtate. However, in Naples, and ſome other parts of Italy, where its violence is not to be compared with that of Palermo, it is often attended with putrid diſorders, and ſeldom fails to produce almoſt a general dejection of ſpirits. But there the ſirocc laſts for many days, and even for weeks; ſo that, as its effects are different, it probably proceeds from a different cauſe. Some have ſuppoſed that this is the ſame wind with that which is ſo dreadful in the ſandy deſarts of Africa, where it ſometimes proves mortal in the ſpace of half an hour; but that in its paſſage over the ſea, it is cooled and deprived of its tremendous influence, before it reaches Sicily. If this were true, we might expect to find it moſt violent on that ſide of the iſland that lies neareſt to Africa, which is not the caſe; though it is poſſible, that its heat may be again increaſed by its paſſage acroſs the iſland to Palermo, near the moſt northern part: and beſides, this city is almoſt ſurrounded by very high mountains, the ravines and vallies betwixt which are entirely parched up and burning hot at this ſummer ſeaſon of the year. Theſe likewiſe contain ſprings of warm water, the ſteams of which may increaſe the heat, and at the ſame time ſoften the air, ſo as to diſarm it of its noxious qualities. It is a practice too, at this ſeaſon, to burn heath and bruſh-wood on the mountains, which muſt ſtill add to the heat of the air.

SIROD, in *Geography*, a town of France, in the department of the Jura; 3 miles S.S.W. of Nozeroy.

SIRO-DEVA, a name of the Hindoo deity *Siva*; which ſee.

SIRONG, in *Geography*. See Seronge.

SIROTE, a town of Bootan; 60 miles S.E. of Taſſaſudon. N. lat. 27° 18′. E. long. 90° 25′.

SIROWY, a circar of Hindooſtan, in Agimere, lying on each ſide of the river Puddar, bounded N. by Joodpour, E. by Mewat, S. by Oudipour, and W. by ſandy deſerts. The chief towns are Sirowy and Jalour.

SIRPY, a town of Hindooſtan, in the Myſore; 30 miles S.E. of Chittledroog.

SIRR. See Sir.

SIRSA, a town of Bengal; 30 miles S.E. of Ghidore.

SIRVENT, or Vasir, a town of Charaſm; 60 miles S.E. of Urghenz.

SIRUN, a town of Perſia, in the province of Segeſtan, or Seiſtan; 40 miles E. of Zareng.

SIRUPA, a town of New Mexico, in the province of Hiaqui; 80 miles N.E. of Riochico.

SIRZESZYN, a town of Lithuania, on the Dnieper; 50 miles N.E. of Mozyr.

SIS, a town of Aſiatic Turkey, in the government of Sivas; 24 miles S. of Tocat.—Alſo, a town of Aſiatic Turkey, in Caramania; 150 miles E.S.E. of Cogni.

SISAL. See Sical.

SISALO, in *Ancient Geography*, a town of Spain, upon the route from Emerita to Saragoſſa, in paſſing by Luſitania, between Mirobriga and Corcuvium, according to the Itinerary of Antonine.

SISAN, a town of Aſia, in the confines of Cilicia.

SISAPO, *Almaden*, a town of Spain, in Bœtica, towards the eaſt. Suppoſing it to be the ſame with Almaden, it yielded, in the time of the Romans, a mine of quickſilver, in high eſtimation, the produce and revenues of which were of great importance to the republic.

SISAPONE, the ſame with the former, a town of Spain, in the Tarragonenſis, towards the confines of Bœtica, which belonged to the Oreſoni, according to Ptolemy.

SISAR, a river of Africa, in Mauritania Tingitana, between the towns of Chobar and that of Jerſeth, according to Ptolemy.

SISARA Palus, the lake of Siſara, a lake of Africa, being the ſouthern part of the lake Hipponibis, mentioned by Ptolemy.

SISARACA, a town of Spain, in the Tarragonenſis, belonging to the Murbogi. Ptolemy.

SISARIS, *Manſourah*, a river in the eaſtern part of Mauritania Cæſarienſis. Its mouth was five leagues N.E. of that of the river Naſava.

SISARMES, in *Ancient Armour*. See GISARMES.

SISARUM, in *Botany*, the Skirret, an eatable root, now out of uſe with us, though cultivated in the days of Gerarde and Parkinſon. Its flavour is ſaid to be aromatic, with a ſweetneſs not acceptable to every body, and of a flatulent, or indigeſtible, quality. See SIUM.

SISAURANUM, in *Ancient Geography*, a famous town of Perſia, at the diſtance of two journies from Dara and three miles from Rabdian, according to Procopius. This town was taken and razed by the emperor Juſtinian.

SISCAR, in *Geography*, a town of Spain, in Arragon; 19 miles E.N.E. of Balbaſtro.

SISCO, a town of the iſland of Corſica; 6 miles N. of Baſtia.

SISECKE, a river of Germany, in the county of Mark, which runs into the Lippe, a little below Lunen.

SISIBOU, or SISSIBOU, a town of Nova Scotia, on the W. coaſt; 25 miles S.S.E. of Annapolis.

SISINILLA, a town of the iſland of Cuba; 12 miles E.N.E. of Trinidad.

SISKIN, in *Ornithology*. See SPINUS.

SISNOVIA, in *Geography*, a town of Iſtria; 3 miles S.E. of Pedena.

SISOGUICHI, a town of Mexico, in the province of Biſcay; 140 miles W. of Parral.

SISOLSK, UST, a town of Ruſſia, at the confluence of the rivers Vim and Vitchegda, in the province of Uſtiug; 120 miles N.E. of Uſtiug. N. lat. 61° 55′. E. long. 49° 40′.

SISON, in *Botany*, a name adopted from Dioſcorides, whoſe σισων, as he tells us, "is a little ſeed, produced in Syria, reſembling parſley, oblong, black, and of a hot taſte. Many of theſe ſeeds grow together at the tops of the ſtalks." There can be little doubt that this deſcription applies to one of the umbelliferous order, but to what preciſe ſpecies or genus, can ſcarcely be gueſſed; nor did Dr. Sibthorp, when he examined the famous manuſcript of Dioſcorides at Vienna, find any thing to guide him reſpecting this point.—Linn. Gen. 139. Schreb. 188. Willd. Sp. Pl. v. 1. 1436. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 315. Prodr. Fl. Græc. Sibth. v. 1. 195. Ait. Hort. Kew. v. 2. 145. Purſh 194. Juſſ. 221.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juſſ.

Gen. Ch. *General Umbel* of fewer than ſix unequal rays; *partial* of fewer than ten unequal rays. *General Involucrum* of about four unequal leaves; *partial* ſimilar to it. *Perianth* ſcarcely diſcernible. *Cor. Univerſal* uniform; all the flowers fertile; *partial* equal, of five lanceolate, inflexed, flattiſh petals. *Stam.* Filaments five, capillary, the length of the corolla; anthers ſimple. *Piſt.* Germen inferior, nearly ovate; ſtyles two, reflexed; ſtigmas obtuſe. *Peric.* Fruit ovate, ſtriated, ſeparating into two parts. *Seeds* two, ovate, convex and ſtriated on one ſide, flat on the other.

Eſſ. Ch. Flowers uniform, all fertile. General and partial involucrum each of few leaves. Fruit ovate, ſtriated. Petals lanceolate, inflexed.

1. S. *Amomum*. Hedge Honewort, or Baſtard Stone-parſley. Linn. Sp. Pl. 362. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 954. Jacq. Hort. Vind. v. 3. 13. t. 17. (Petroſelinum macedonicum Fuchſii; Ger. Em. 1016.)—Leaves pinnate. Umbels erect, of about four rays.—Native of England, Germany, the ſouth of France, and the neighbourhood of the Bithynian Olympus. With us it chiefly occurs in moiſt ſhady places, where the ſoil is marly or chalky, flowering in Auguſt. The *root* is ſpindle-ſhaped, annual or biennial. *Stem* two or three feet high, branched, widely ſpreading, leafy, ſtriated, ſmooth. *Leaves* dark green, ſmooth, ſimply pinnate, with a terminal lobed leaflet; the upper ones more compound or divided; all ſharply ſerrated and cut. *Umbels* numerous, terminal, ſolitary, erect when in flower, white, but ſmall and inconſpicuous. *Fruit* roundiſh-ovate. *Seeds* aromatic and pungent when ripe. In a green ſtate, their ſcent, like that of the whole herb, when bruiſed, is peculiarly nauſeous, ſomewhat like *Coriander*, but even worſe. Theſe ſeeds have been known in the European Pharmacopæas by the name of *Amomum*, no one knowing what was the true *Amomum*; and have been celebrated as diuretic, uſeful in the ſtone and gravel, &c.; but they are now out of uſe, probably with no loſs to the patient.

2. S. *ſegetum*. Corn Honewort. Linn. Sp. Pl. 362. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 228. Jacq. Hort. Vind. v. 2. 63. t. 134. (Selinum ſii foliis; Ger. Em. 1018. Sium terreſtre, ſeu ſegetale; Moriſ. ſect. 9. t. 5. f. 6.)—Leaves pinnate; leaflets roundiſh, numerous. Umbels drooping, ſhapeleſs.—Native of England and Switzerland, but rare, chiefly in moiſt low fields, on a calcareous ſoil, flowering in Auguſt. Scarcely any body but a curious botaniſt would obſerve this little plant, which appears like a ſtarved ſpecimen of many a more common kind. The numerous crowded *leaflets*, imbricated, in a manner, before they expand, and the ſtraggling, drooping, little *umbels*, are peculiar. The *flowers*, and their *anthers*, are tinged with purple.

3. S. *canadenſe*. Three-leaved Canadian Honewort. Linn. Sp. Pl. 363. Willd. n. 3. Ait. n. 3. (Chærophyllum canadenſe; Purſh 195. Myrrhis canadenſis; Riv. Pentap. Irr. t. 54. M. canadenſis trilobata; Moriſ. ſect. 9. t. 11. f. 4.)—Leaves ternate. General involucrum wanting. Seeds elliptic-oblong.—Common in the woods of North America, from Canada to Virginia, flowering in July. *Purſh*. *Root* perennial, of many tapering fibres. *Stem* two feet high, branched, round, ſmooth, leafy. *Leaflets* ſmooth, broad, acute, doubly and ſharply ſerrated; the lateral ones, of the lower leaves, often deeply divided, and their intermediate one ſometimes three-lobed. *Umbels* ſlender, unequal, deſtitute of a general involucrum, and with very ſmall partial ones, but otherwiſe having the genuine habit of this genus, and no character of *Chærophyllum*. *Fruit* elliptic-oblong, ſtrongly ribbed, ſmooth, crowned with the ſmall, conical, converging ſtyles.

4. S. *Ammi*. Fennel-leaved Honewort. Linn. Sp. Pl. 363. Willd. n. 4. Jacq. Hort. Vind. v. 2. 95. t. 200. (Ammi; Camer. Epit. 522. Matth. Valgr. v. 2. 120. Riv. Pentap. Irr. 91. A. perpuſillum; Lob. Ic. 725. Ger. Em. 1037.)—Leaves triply pinnate; the radical ones with linear ſegments; the upper ſetaceous.—Native of Portugal, Italy, and Egypt. A ſlender, annual, ſmooth *plant*, about a foot high, with an aromatic parſley-like ſmell. Segments of the *leaves* alternate, or ternate, acute. *General umbels* of five or more rays, with an unequal, ſomewhat leafy, *involucrum*; *partial* of numerous ſhort rays; their *involucral leaves* linear, minutely fringed. Jacquin ſays his plant had neither general nor partial *involucrum*. *Flowers* white. *Germen* in the original Linnæan ſpecimen, from Clifford's garden, ovate, minutely granulated, of which mark we find no account. The ripe *ſeeds* are deſcribed by Jacquin and Rivinus as ovate.

5. S. *puſillum*. Dwarf Honewort. Michaux Boreal-Amer. v. 1. 168. Purſh n. 1. (Daucus divaricatus;

Walt. Carol. 114, according to Purſh.)—"Leaves twice-ternate, many-cleft. Partial umbels of three to five flowers. Seeds roughiſh." In dry ſandy fields in Carolina, flowering in April and May. *Root* annual. *Purſh.*

6. S. *trifoliatum.* Three-leaved Carolina Honewort. Michaux, ibid. Purſh n. 2.—"Leaves all ternate; leaflets toothed; the lower ones oval, with two or three lobes; upper oval-lanceolate. Umbel terminal, ſtalked, ſolitary. Seeds roundiſh."—Found by Michaux in North Carolina.

7. S. *marginatum.* White-edged Honewort. Michaux, ibid. Purſh n. 3.—"Leaves pinnate; the upper ones quinate; leaflets all ſeſſile, lanceolate, entire, bordered with white. General and partial involucrum wanting."—In wet meadows, from Virginia to Carolina, flowering in July and Auguſt. Perennial. *Purſh.*

8. S. *ſalſum.* Salt Honewort. Linn. Sp. 181. Willd. n. 7. ("Peucedanum redivivum; Pallas Act. Petrop. 1779. v. 2. 252. t. 8. f. 1—3.")—Leaves radical, doubly pinnate; leaflets digitate, ſomewhat whorled. Stem leafleſs, panicled, with numerous umbels.—In dry, muddy, ſalt plains about the Wolga; gathered by Pallas, whoſe ſpecimen is before us. The *root* is perennial. *Leaves* all radical, appearing in the ſpring, ſtalked, ſpreading, three inches long, doubly compound, the *leaflets* crowded as if whorled, in many ſmooth, oblong, briſtle-pointed ſegments, all together reſembling ſome feathery ſort of *Conferva.* *Stem* appearing after the leaves are gone, twelve or eighteen inches high, ſlender, round, ſmooth, bearing in Auguſt a panicle, alternately compounded, of ſlender ſpreading *umbels*, each of from three to five rays. At the baſe of each branch is a ſharp membranous-bordered leaf, or *bractea.* *Partial umbels* of five or ſix capillary rays. *General involucrum* of two or three ſmall membranous leaves; *partial* like it, but ſmaller. *Flowers* white. *Germen* ovate. *Fruit* more oblong, ſmooth, obſcurely ribbed. Some of the *flowers* in each partial umbel do indeed appear to be abortive, whence perhaps Pallas referred this curious ſpecies to *Peucedanum;* but we find no traces of a wing to the ſeeds, to confirm that meaſure.

9. S. *crinitum.* Capillary-leaved Honewort. Willd. n. 8. "Pallas Act. Petrop. 1779. v. 2. 250. t. 7."—"Radical leaves triply pinnate: thoſe of the ſtem bipinnate; leafleſs briſtle-ſhaped. General involucrum of many doubly pinnate leaves."—Native of Siberia. *Pallas.* We have not ſeen the plate cited, but the *involucrum* is deſcribed as doubly compound and ſetaceous.

Two Britiſh Linnæan ſpecies, the *inundatum* and *verticillatum,* are removed, in the Flora Britannica, from the preſent genus; the former to Hydrocotyle, and the latter to Sium; ſee thoſe articles. We are as confident of the propriety of this alteration, as it is poſſible to be on any queſtion regarding the genera of umbelliferous plants. *Siſon* itſelf is conſidered, by ſome botaniſts, as a doubtful genus, and is reduced to *Sium* by Lamarck in his Dictionary, v. 1. 404.

Sison *Syriacum,* a name given by ſome authors to the ammi, or biſhop's weed, a plant whoſe ſeeds were once much uſed in medicine.

SISSA, in *Geography,* a town of the duchy of Parma; 11 miles N.N.W. of Parma.

SISSACH, a town of Switzerland, in the canton of Bâle; 13 miles S.E. of Bâle.

SISSAN, a town of Iſtria; 3 miles E.N.E. of Pola.

SISSITIEPTERIS, in *Botany,* a name uſed by Pliny, and ſome others of the old authors, for the pimpinella, or burnet.

SISSONNE, in *Geography,* a town of France, in the department of the Aiſne, and chief place of a canton, in the diſtrict of Laon; 10 miles E. of Laon. The place contains 1105, and the canton 10,327 inhabitants, on a territory of 337½ kilometres, in 20 communes.

SISSOPOLI. See Sizeboli.

SISSUER, a town of Hindooſtan, in Oude; 24 miles E.S.E. of Manickpour.

SISTAN, or Segestan. See Seistan.

SISTER, a female born of the ſame parents.

Sister-*Blocks,* in *Block-Making,* are blocks made of aſh, ſimilar to two ſingle blocks, and turned out of a ſolid piece, about two inches long, one above the other: between the blocks is a ſcore for a middle-ſeizing; a round head is turned at each end, and hollowed underneath, to contain the end-ſeizings: along the ſides, through which the pins are driven, is a groove, large enough to receive part of the top-maſt ſhroud, in which it is ſeized. In theſe blocks reeve the lifts, and reef-tackle pendants of the topſail-yards.

SISTERON, in *Geography,* a town of France, and principal place of a diſtrict, in the department of the Lower Alps, ſituated on the Durance, with a ſmall caſtle on a rock; and before the revolution the ſee of a biſhop, ſuffragan of Aix; 15 miles N.W. of Digne. The place contains 3891, and the canton 7070 inhabitants, on a territory of 230 kilometres, in 9 communes. N. lat. 44° 11′. E. long. 6° 1′.

SISTERS, two ſmall iſlands in the Red ſea. N. lat. 19° 30′. E. long. 39° 15′.—Alſo, two very ſmall iſlands near the coaſt of Sumatra, covered with wood, lying in S. lat. 5° 0½′. E. long. 106° 12′; nearly N. and S. from each other, and ſurrounded by a reef of coral rocks; the whole circumference of which is about four or five miles.

SISTERSDORF. See Zistersdorf.

SISTOTREMA, in *Botany,* a genus of *Fungi,* of which ſeveral ſpecies are deſcribed, and ſome figured, in Albertini and Schweiniz's very learned work, entitled *Conſpectus Fungorum in Luſatiæ ſuperioris agro Niſkienſi creſcentium,* p. 260—264. We, however, find there no generic character. The plants ſeem moſt akin to Hydnum; ſee that article. The name appears to be compounded of συςω and τρημα, alluding to the regular rows of pores; but if ſo, it ought to be *Syſtotrema.*

SISTOVA, or Szisto, in *Geography,* a town of European Turkey, in Bulgaria, on the right bank of the Danube; 25 miles E. of Nicopoli. N. lat. 43° 45′. E. long. 24° 44′.

SISTROID *Angle.* See Angle.

SISTRUM, a ſacred muſical inſtrument with the ancient Egyptians; and one that is ſtill uſed by the Abyſſinians in religious ceremonies.

Spon deſcribes it of an oval form, made in manner of a racket, with three ſticks traverſing it breadthwiſe, which, playing freely by the agitation or beating of the inſtrument, yielded a kind of ſound, which, to the ancients, ſeemed melodious. The upper part was adorned with three figures; that of a cat with a human face in the middle, the head of Iſis on the right ſide, and the head of Nephthys on the left. The repreſentation which we have given in the *Plate of Muſic* was drawn from an ancient ſiſtrum preſerved in the library of St. Genevieve at Paris. It has been diſputed by the abbé Winckelman, whether the ſiſtrum was of very high antiquity in Egypt, becauſe it did not appear in the hands of ſuch Egyptian ſtatues as he had ſeen at Rome; but as there is one in the hand of a very ancient ſtatue of Iſis, which doctor Pococke brought into England from Egypt, it puts that point of muſical hiſtory out of all diſpute. The ſiſtrum appears in the Iſiac Table; and Apuleius makes an old Greek invoke an Egyptian prieſt "by the ſtars in the firmament; by the infernal divinities; by the elements which compoſe the univerſe; by the ſilence of the night; by the ſanctuary in the temple of Coptos; by the increaſe of the Nile; by the myſteries of Memphis; and by the ſiſtrum of Pharos." By Pharos, an Egyptian iſland, was here figuratively meant, all Egypt.

Mr. Malcolm takes the ſiſtrum to have been no better than a kind of rattle. Jer. Boſius has an expreſs treatiſe on the ſiſtrum, intitled, " Iſiacus de Siſtro."

Oiſelius obſerves, that the ſiſtrum is found repreſented on ſeveral medals; and alſo on taliſmans. Oſiris, on ſome medals, is painted with the head of a dog, and with a ſiſtrum in his hand.

SISUPALA, in *Hindoo Mythology*, is the name of a malignant perſonage, into whoſe body an inſolent celeſtial was doomed to be re-born on earth, as an expiation of his offence. He was ſlain by Kriſhna.

SISY-*ſur-Ourcq*, in *Geography*. See LIZY-*ſur-Ourcq*.

SISYMBRIUM, in *Botany*, Σισυμβριον of the Greeks, at leaſt the Σ. ἥμερον of Dioſcorides is probably included under our preſent genus. His firſt ſpecies, celebrated for its fragrance, has been ſuppoſed Wild Thyme, and by ſome our *Mentha hirſuta*, which laſt has alſo occaſionally a very ſweet ſmell. De Theis ſeems not to have been aware of this; nor might the plant in queſtion find a place in garlands dedicated to Venus, ſo much on account of its odour, as of its warm and cordial properties.—Linn. Gen. 338. Schreb. 441. Willd. Sp. Pl. v. 3. 489. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 700. Prodr. Fl. Græc. Sibth. v. 2. 18. Ait. Hort. Kew. v. 4. 111. Purſh 440. Juſſ. 239. Lamarck Dict. v. 7. 201. Illuſtr. t. 565.—Claſs and order, *Tetradynamia Siliquoſa*. Nat. Ord. *Siliquoſæ*, Linn. *Cruciferæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of four lanceolate-linear, ſpreading, coloured, deciduous leaves. *Cor.* cruciform, of four oblong ſpreading petals, often leſs than the calyx with very ſmall claws. *Stam.* Filaments ſix, longer than the calyx, of which the two oppoſite ones are rather the ſhorteſt; anthers ſimple. *Piſt.* Germen oblong-thread-ſhaped; ſtyle ſcarcely any; ſtigma obtuſe. *Peric.* Pod long, incurved, gibbous, round, with two cells and two ſtraight valves, which are rather ſhorter than the partition. *Seeds* numerous, ſmall.

Eſſ. Ch. Pod burſting, with nearly ſtraight valves. Calyx and corolla ſpreading.

A copious genus, tolerably natural as to habit, but not very diſtinctly defined; of which the 14th edition of Linn. Syſt. Veg. contains twenty-nine ſpecies, and Willdenow's Sp. Pl. fifty-three. Nine of them are found wild in Britain. We ſhall deſcribe all the latter, and give a general view of the five ſections, into which the whole genus is divided by Linnæus. Mr. Brown, in his very ingenious attempt at reforming the genera of the claſs *Tetradynamia*, in Ait. Hort. Kew. has ſeparated ſome ſpecies, principally of the firſt ſection, into a genus called *Naſturtium*, and he has referred two of the Britiſh ones to SINAPIS, (ſee that article,) and one to BRASSICA. Reſpecting theſe very ſpecies, there has heretofore been a difference of opinion among botaniſts, as will appear when we come to ſpeak of them in order. The whole genus is herbaceous, either annual or perennial, with alternate *leaves*, various, and ſometimes inconſtant, in ſhape and diviſion moſtly ſmooth. The *flowers* are almoſt invariably yellow; though always white in the firſt ſpecies.

Sect. 1. *Pods declining, ſhort.* Eleven ſpecies in Willdenow.

S. *Naſturtium.* Common Water-creſs. Linn. Sp. Pl. 916. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 855. Curt. Lond. faſc. 6. t. 44. Woodv. Med. Bot. t. 48. Fl. Dan. t. 690. (Naſturtium officinale; Br. in Ait. Hort. Kew. v. 4. 110. N. aquaticum, ſive Cratevæ Sium; Ger. Em. 257.)—Pods declining. Leaves pinnate; leaflets roundiſh-heart-ſhaped.—In clear rivulets and ſprings throughout Europe, from Sweden to Greece, as well as in North America; and, according to Mr. Purſh, on the high mountains of the iſland of Dominica. It is perennial, flowering in June and July. No Britiſh plant is in ſuch popular requeſt as a ſalad; the young leaves having a pleaſantly warm pungent flavour, and being ſuppoſed, like ſcurvy-graſs, to purify the blood. The *ſtems* are branched, angular and leafy, floating by the help of their foliage, ſending down long, white, fibrous *roots*, and terminating in aſcending corymboſe tufts, of numerous, white, purpliſh-tinted *flowers*, ſucceeded by long cluſters of ſhort, gibbous, recurved, ſtalked *pods*. The *leaves* are ſmooth, of a dark ſhining green, conſiſting of five or ſeven leaflets, the terminal one largeſt. There can be little doubt of this being σισύμβριον ἥμερον of Dioſcorides. The modern Greeks call it νεροκάρδαμον; a word ſynonimous with Water-creſs.

S. *ſylveſtre.* Creeping Water Rocket. Linn. Sp. Pl. 916. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 2324. Curt. Lond. faſc. 3. t. 41. (Naſturtium ſylveſtre; Br. in Ait. Hort. Kew. v. 4. 110. Eruca aquatica; Ger. Em. 248. Brachiolobos ſylveſtris; Allion. Pedem. v. 1. 278. t. 56. f. 2.)—Pods declining. Leaves pinnate; leaflets lanceolate, deeply ſerrated or cut.—Native of gravelly waſte ground, in marſhy places, or near rivers, flowering from June to September, in ſeveral parts of England, as well as in Germany, Switzerland, and France. Dr. Sibthorp obſerved it on mount Hæmus. The *root* creeps ſo extenſively, that the *pods* are moſtly abortive. *Stems* erect, leafy, angular, zig-zag, roughiſh, ſomewhat panicled. *Leaves* ſmooth; the leaflets of the lower ones decurrent, variouſly toothed; of the upper narrower, more ſlightly cut or ſerrated. *Flowers* of a golden yellow; their cluſters after flowering elongated and zig-zag.

Willdenow ſuppoſes *S. lippizenſe*, Jacq. Ic. Rar. t. 505, to be a variety of this, with more entire leaflets; but it is drawn with a fibrous, not creeping, root.

S. *terreſtre.* Annual Water Rocket. Curt. Lond. faſc. 5. t. 49. Fl. Brit. n. 3. Engl. Bot. t. 1747. (S. paluſtre; Willd. n. 3. Pollich v. 2. 230. Purſh n. 2. S. amphibium α; Hudſ. 296. Naſturtium terreſtre; Br. in Ait. Hort. Kew. v. 4. 110. Raphanus aquaticus, foliis in profundas lacinias diviſis; Bauh. Prodr. 38.)—Pods declining, turgid. Leaves pinnatifid, unequally toothed. Root ſimply fibrous. Petals ſcarcely ſo long as the calyx.—Found in watery places, about the ſides of ditches, in the north of Europe, as well as America. Very plentiful about London, flowering from June to September.—The *root* is annual, ſometimes branching at the top, but not creeping. *Stem* a foot high, nearly upright, branched, leafy, furrowed, ſmooth. *Leaves* lyrate, unequally toothed. *Flowers* numerous, yellow, ſmall and inconſpicuous, ſucceeded by ſhort, turgid, erect *pods*, whoſe partial ſtalks are widely extended.

S. *amphibium.* Great Water Rocket, or Radiſh. Linn. Sp. Pl. 917. Willd. n. 4. Fl. Brit. n. 4. Engl. Bot. t. 1840. Purſh n. 3. Fl. Dan. t. 984. (S. amphibium β; Hudſ. 296, and γ, 297. Naſturtium amphibium; Br. in Ait. Hort. Kew. v. 4. 110. Raphanus aquaticus alter; Bauh. Prodr. 38. R. aquaticus; Ger. Em. 240.)—Pods declining, on longiſh partial ſtalks. Leaves oblong, pinnatifid or ſerrated. Petals longer than the calyx.—Not rare in the rivers and ditches of America, and the north of

Europe; frequent in England, flowering copiouſly in July and Auguſt. In running ſtreams it grows to a great ſize, with long floating *ſtems,* throwing out abundance of white fibrous radicles, and bearing, under water, deeply pectinated *leaves.* On the neighbouring banks it is found ſmaller, with broader, and merely ſerrated, foliage. The primary *roots* are perennial, long, perpendicular, not creeping. The *leaves* which grow out of the water are more or leſs oblong, jagged, claſping the ſtem with their dilated baſe; the radical ones ſtalked. *Flowers* yellow, not very bright. *Pods* ſhort and ſmall, often abortive. This ſeems to be the plant which Chateaubriand obſerved in Suffolk, and of which he has given ſo extravagant an account in his travels; as if the works of the Creator were not, of themſelves, ſufficiently admirable, without bombaſt or exaggeration.

S. *tanacetifolium.* Tanſy-leaved Wild-rocket. Linn. Sp. Pl. 916. Willd. n. 6. Ait. n. 12. (Eruca, n. 460; Hall. Hiſt. v. 1. 200. E. tanaceti folio; Moriſ. ſect. 3. t. 6. f. 19. E. fruticoſo, con foglie di tanaceto, indiana; Zanon. Iſt. 86. t. 33.)—Leaves pinnate; leaflets lanceolate, cut or deeply ſerrated; hoary beneath; the ultimate ones confluent. Pods erect, ſomewhat club-ſhaped.—Native of thickets and groves, on the loftieſt alps of Savoy and Switzerland, but eſteemed one of the rareſt plants of thoſe countries. We gathered it in ſeed on mount Cenis, Auguſt 13, 1787. Miller is ſaid to have cultivated this *Siſymbrium* in 1731, and we believe it is ſtill to be met with in curious collections. The *root* is perennial. *Stem* two or three feet high, clothed with very handſome ſpreading *leaves,* finely downy and hoary beneath, and often beſprinkled with minute ſtarry hairs on their upper ſurface. *Flowers* of a golden yellow, numerous, in terminal corymbs, growing out into long, lax cluſters of ſmooth, erect, obtuſe *pods,* half an inch or more in length, tapering at their baſe; their partial *ſtalks* about the ſame length, aſcending obliquely.

S. *tenuifolium.* Wall Wild-rocket. Linn. Sp. Pl. 917. Willd. n. 9. Fl. Brit. n. 5. Engl. Bot. t. 525. (Braſſica muralis; Hudſ. 290. Curt. Lond. faſc. 3. t. 38. Sinapis tenuifolia; Br. in Ait. H. Kew. v. 4. 128. Sinapi erucæ folio; Bauh. Pin. 99. Tourn. Inſt. 227. S. tertium; Matth. Valgr. v. 1. 516. Eruca ſylveſtris; Ger. Em. 246.)—Pods erect, ſomewhat beaked. Leaves ſmooth, pinnatifid or bipinnatifid, nearly entire; the uppermoſt undivided.—Native of old walls and rubbiſh, in England, Germany, Switzerland, and France, as well as about Conſtantinople, flowering from July to October. The *root* is perennial. *Plant* buſhy, ſmooth, ſomewhat glaucous. *Leaves* acute, variouſly ſinuated and pinnatifid; their ſegments lanceolate. *Flowers* large, lemon-coloured, ſtrongly ſcented. *Pods* diſtant, tipped with the ſlightly elongated *ſtyle.*

S. *ſagittatum.* Arrow-leaved Wild-rocket. Willd. n. 10. (S. molle; Jacq. Coll. v. 1. 68. Ic. Rar. t. 122. Naſturtium ſagittatum; Br. in Ait. H. Kew. v. 4. 111.)—Downy. Leaves oblong, with ſhallow teeth; the radical ones haſtate; the reſt claſping the ſtem with their arrow-ſhaped baſe.—Native of Siberia. Sent to Kew, by Pallas, in 1780. The *root* is ſpindle-ſhaped, perennial. Whole *plant* clothed with ſoft, depreſſed, ſomewhat ſtellated down. *Leaves* bluntiſh, bearing ſome reſemblance to thoſe of Shepherd's Purſe. *Flowers* yellow, ſucceeded by long cluſters of drooping downy *pods.*

Sect. 2. *Pods often axillary, nearly ſeſſile.* Five ſpecies.

S. *polyceratium.* Dandelion-leaved Wild-rocket. Linn. Sp. Pl. 918. Willd. n. 13. Ait. n. 11. Prodr. Fl. Græc. n. 1535. Jacq. Hort. Vind. v. 1. 34. t. 79. (Irio alter; Matth. Valgr. v. 1. 524. Eryſimum alterum italicum; Ger. Emac. 254.)—Pods axillary, aggregate, awl-ſhaped, nearly ſeſſile. Leaves wavy or toothed.—Native of Switzerland, France, Italy, and Greece. Dr. Sibthorp found it, very common, throughout the laſt-mentioned country and the iſlands of the Archipelago, in waſte ground, court-yards, and about villages, as Dioſcorides reports of his ερυσιμον, which therefore the Oxford profeſſor judged this plant to be; perhaps rightly; but the deſcription of the Greek author, particularly the yellow flowers, and the terminal pods, anſwer better to our *Eryſimum officinale* (*Siſymbrium officinale,* Br. in Ait. H. Kew. n. 1.), which is alſo a Greek plant. The preſent *Siſymbrium,* a mean and ill-looking weed, is perfectly naturalized about Bury, in Suffolk, and might be taken for a native Britiſh plant, had we not the authority of ſir T. G. Cullum, for its having eſcaped, many years ſince, from the botanic garden of the Rev. Mr. Laurence of that town. The *root* is annual. *Stems* branched, decumbent, leafy, ſmooth, gradually elongated after flowering. *Leaves* about an inch long, on ſhort ſtalks, ſimple, ſomewhat haſtate, ſlightly toothed or wavy, ſmooth. *Flowers* ſmall, white, axillary, on ſhort ſtalks, two or three together. *Pods* rather curved, an inch long, uneven, ſmooth, with a zig-zag furrow along each ſide.

S. *toruloſum.* Rough-podded Wild-rocket. Desfont. Atlant. v. 2. 84. t. 159. Willd. n. 16. Sm. Fl. Græc. Sibth. t. 632, unpubliſhed.—Pods racemoſe, ſeſſile, awl-ſhaped, hairy. Stem diffuſe. Leaves lanceolate, toothed.—Native of uncultivated fields, in Tunis, and the iſle of Cyprus. An annual, branched, nearly proſtrate *herb,* very like the laſt in general appearance, but the *leaves* are longer, truly lanceolate, and regularly toothed. *Flowers* terminal, denſely corymboſe, white, their ſtalk lengthening out into a long *cluſter,* or rather *ſpike,* of crowded, ſeſſile, ſpreading, rugged, hairy *pods,* each about an inch in length.

Sect. 3. *Stem for the moſt part naked.* Eight ſpecies.

S. *murale.* Sand Wild-rocket. Linn. Sp. Pl. 918. Willd. n. 17. Dickſ. Dr. Pl. 12. Engl. Bot. t. 1090. Fl. Brit. 1401. (Eruca viminea, iberidis folio, luteo flore; Barrel. Ic. t. 131. Sinapis muralis; Br. in Ait. H. Kew. v. 4. 128.)—Pods erect. Stem ſpreading, ſhort, roughiſh. Leaves lanceolate, deeply ſerrated.—Native of France, Italy, and the iſle of Thanet, in waſte ſandy ground, flowering in autumn. *Root* truly annual. *Stems* branching, diffuſe, often very ſhort, leafy, round, more or leſs rough with deflexed hairs. *Leaves* of a graſs green, tapering at the baſe into long footſtalks; their margin deeply and irregularly ſerrated. *Flowers* ſmaller than thoſe of *S. tenuifolium,* their *corymbs* becoming long looſe *cluſters* of erect, cylindrical, ſmooth *pods,* on ſpreading, hairy ſtalks. *S. Erucaſtrum,* Gouan Illuſtr. t. 20, is preciſely this plant, not a variety.

S. *monenſe.* Dwarf Sea Wild-rocket. Linn. Sp. Pl. ed. 1. 658. Fl. Brit. n. 6. Engl. Bot. t. 962. Willd. n. 18. Lightf. Scot. 353. t. 15. f. 1. (Braſſica monenſis; Hudſ. 291. Br. in Ait. H. Kew. v. 4. 124. Eruca monenſis laciniata, flore luteo majore; Dill. Elth. 135. t. 111. f. 135.)—Pods nearly erect, quadrangular, with a long beak. Leaves pinnatifid, ſlightly hairy. Stems ſimple, almoſt naked, ſmooth.—Native of the ſandy ſhores of Bute, Arran, and the weſt of Scotland, as well as of Cumberland, and the iſles of Walney, Angleſea, and Man. *Root* thick, woody, and perennial. *Stems* ſeveral, a ſpan high, leafy at the bottom only. *Leaves* almoſt all radical, numerous, ſtalked, rather fleſhy and glaucous; their ſegments deep, tolerably uniform, either entire, or with broad inciſions. *Flowers* large, numerous, lemon-coloured, corymboſe, succeeded by a long cluſter of ſmooth, obſcurely quadrangular, upright, ſtalked, long-beaked *pods.* *Calyx* leſs ſpreading than in moſt of the ſpecies, its leaves hairy at the tips. *Petals* veined.—We have been led to doubt whether Gerard's plant from Provence, deſcribed in the ſecond edition of Sp. Pl. and preſerved in the Linnæan herbarium, be the ſame with our's; becauſe its *flowers* are ſmaller, and the veins of their *petals* ſcarcely diſcernible, though in our's very ſtrong. It may nevertheleſs be a mere variety. We find in its young *pods* plain indications of the remarkable lanceolate beak, half the length of the *pod* itſelf, ſo ſtriking in our *S. monenſe*, and figured, as well as deſcribed, in Engliſh Botany. Willdenow was miſled by Villars to conſider Gerard's as the ſame with the following.

S. *repandum*. Wavy-leaved Wild-rocket. Willd. n. 19. (S. monenſe; Villars Dauph. v. 3. 350. t. 39, the ſynonyms moſtly, if not entirely, wrong.)—Pods nearly erect, compreſſed, uneven, with a ſhort quadrangular beak. Leaves with wavy teeth, ſmooth. Stems ſimple, ſmooth, quite naked.—Native of the mountains of Dauphiny; our ſpecimen is from Villars himſelf, and proves, notwithſtanding his aſſertion, very diſtinct from the plant of Gerard, mentioned under our preceding ſpecies, as well as from Britiſh ſpecimens of that ſpecies. We have no means of knowing exactly how far the author is correct in Tournefort's ſynonym; but the phraſe *radice craſſâ* anſwers admirably to Gerard's ſpecimen, and not to that of Villars. The *root* of the latter is long and tapering, divided, but not very thick, at the crown, where it bears ſeveral ſimple tufts of ſtalked, oblong, or obovate, bluntiſh *leaves*, about an inch only in length, always quite ſmooth; their margins either wavy, or more or leſs deeply toothed. *Stems* ſolitary, four or five inches high, quite leafleſs, ſimple, round and ſmooth, each bearing from four to nine large corymboſe *flowers*, of a fine yellow. *Calyx* ſmooth, ſlightly ſpreading, a little coloured. *Pods* ſlightly ſpreading, rather longer than the laſt as to their valvular part, meaſuring from one and a half to two inches; but the beak is hardly two lines, inſtead of three-quarters of an inch, long, by which the plants are clearly diſtinguiſhed. Willdenow rightly deſcribes the *valves* of the preſent, which are unequally bunched out by the *ſeeds*, as marked with an elevated line, that makes them ſeem quadrangular; but they are much leſs really ſo than in *S. monenſe*, whoſe *pods* few botaniſts appear to have ſeen.

S. *vimineum*. Ruſhy-ſtalked Wild-rocket. Linn. Sp. Pl. 919. Willd. n. 21. (Eruca pumila, burſæ paſtoris folio; Bocc. Sic. 19. t. 10. f. 2. E. minimo flore, monſpelienſis; Bauh. Hiſt. v. 2. 862; the leaves, as the author obſerves, too ſharp.)—Pods erect, compreſſed, with a ſhort quadrangular beak. Stems widely ſpreading, leafy at the baſe. Leaves ſmooth, obovate; toothed or pinnatifid. Petals erect, ſcarcely exceeding the calyx.—Native of Sicily and the ſouth of France. A hardy annual, which we have had for near twenty years, ſpringing up ſpontaneouſly, in a garden, ſo that it merits a place in Mr. Aiton's work, though of no attractive aſpect, to procure it general notice. The *root* is ſmall and fibrous. *Stems* ſeveral, branching at the very baſe only, from three to eight inches long, widely ſpreading or decumbent, ſimply racemoſe, round, ſlender, ſmooth. *Leaves* numerous, about the bottom of each ſtem, ſtalked, from one to two or three inches long, very obtuſe; either ſimply obovate, entire, and partly wavy, or pinnatifid in a lyrate manner, ſometimes rather deeply. *Flowers* extremely ſmall, with a tawny and purpliſh tinge, ſucceeded by a long cluſter of diſtant *pods*, hardly an inch long, ſmooth, ſlightly unequal in their ſurface, each valve marked with a ſlender elevated line. This ſpecies, though very diſtinct, is ſo much akin to the laſt, that their characters are difficult to define. The *calyx* and *corolla* of the preſent hardly anſwer indeed to the idea of a *Siſymbrium*, but rather to that of *Arabis*.

Sect. 4. *Leaves pinnate, or deeply pinnatifid.* Twenty ſpecies.

S. *Sophia*. Flix-weed. Linn. Sp. Pl. 920. Willd. n. 29. Fl. Brit. n. 7. Engl. Bot. t. 963. Mart. Ruſt. t. 57. Fl. Dan. t. 528. Purſh n. 4. (Sophia chirurgorum; Ger. Em. 1068. Lob. Ic. 738.)—Leaves doubly pinnate, with decurrent ſegments, a little hairy. Petals ſmaller than the calyx.—Native of waſte ground, rubbiſh, and banks throughout Europe, from Sweden to Greece, flowering in ſummer. Mr. Purſh ſpeaks of it as occurring by road-ſides in Virginia, but rarely. We preſume the ſeeds may have been imported from England. The *root* is annual. *Stem* about two feet high, erect, copiouſly clothed with finely divided ſpreading *leaves*, whoſe ultimate diviſions are rather pinnatifid than pinnate. *Flowers* pale yellow, very ſmall and inconſpicuous, denſely corymboſe, ſucceeded by long *cluſters* of ſlender, upright, toruloſe *pods*, on ſlender, ſpreading, partial ſtalks, their valves ſeparating and ſpreading from the baſe, ſomewhat like a *Cardamine*. The herb has been thought uſeful in fluxes.

S. *millefolium*. Mill-foil-leaved Wild-rocket. Willd. n. 28. Ait. n. 14. (Sinapis millefolia; Jacq. Coll. v. 1. 41. Ic. Rar. t. 127.)—Leaves triply pinnate, downy and hoary. Petals larger than the calyx.—Native of the Canary iſlands, from whence Mr. Maſſon brought it in 1779. This is a perennial, ſhrubby, greenhouſe plant, flowering from May to September. Though like the laſt in general aſpect, the *leaves* are more compound and hoary, with uſually more rounded ſegments or leaflets; and the *flowers* are much more conſpicuous, on account of their ſpreading yellow *petals*, double the length of the *calyx*.

S. *Irio*. London Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 36. Fl. Brit. n. 8. Engl. Bot. t. 1631. Curt. Lond. faſc. 5. t. 48. Jacq. Auſtr. t. 322. (Eryſimum latifolium majus glabrum; Bauh. Pin. 101. Moriſ. ſect. 3. t. 3. f. 3, at the bottom. Irio lævis apulus, erucæ folio; Column. Ecphr. 264. t. 265.)—Leaves runcinate, toothed, naked. Stem ſmooth. Pods erect, very long, thread-ſhaped.—Native of cultivated ground throughout Europe. Very common about London, where it was ſuppoſed by the ſapient advocates of ſpontaneous generation, to have been generated in conſequence of the great fire, in 1666. If, therefore, we confide in the bold aſſertion on the Monument, or the inſcription on the fat boy at Pye-corner, this plant ought to be a cure for popery, or "the ſin of gluttony," or for both. However this may be, the *root* is annual, the whole *herb*, except the upper *flower-ſtalks* and *calyx* occaſionally, is invariably ſmooth, with an acrid flavour, like muſtard. *Stem* erect, about two feet high, round, leafy, ſlightly zigzag, moſtly branched. *Leaves* none of them truly pinnate, but deeply pinnatifid, with ſpreading or reflexed oblong lobes, moſt toothed at their upper or fore edge. *Flowers* corymboſe, numerous, ſmall, yellow; their *petals* ſpreading, longer than the *calyx*. *Pods* an inch and a half long, very ſlender, on partial ſtalks, about a quarter of an inch in length, all together compoſing a long lax *cluſter*. *Stigma* ſeſſile.

S. *Loeſelii*. Loeſel's Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 38. Jacq. Auſtr. t. 324. (Turritis Loeſelii; Br. in Ait. Hort. Kew. v. 4. 109. Eryſimum hirſutum, ſiliquis erucæ; Loeſ. Pruſſ. 69. t. 14. Rapiſtrum montanum, irionis folio, macroleptoceraton; Column. Ecphr. 266. t. 268.)—Leaves runcinate, toothed, hairy. Stem rough with deflexed briſtles. Pods erect, thread-ſhaped, on long ſpreading ſtalks.—Native of Pruſſia, Auſtria, France, Italy, and Greece. More branched than the laſt, from which it differs in having the *ſtem* clothed with deflexed hairs, found more ſparingly on the *flower-ſtalks*, which latter agree in length and ſlenderneſs with thoſe of *S. Irio*. Nor do the *leaves* differ much in ſhape from that plant, though diſtinguiſhed by their hairineſs. The length and ſlenderneſs of the *pods*, in the Linnæan ſpecimen, likewiſe accord with *Irio;* but in one from Jacquin they are ſhorter, as expreſſed in his plate. The *ſtigma* is ſeſſile. There are, in the Linnæan and Bankſian collections, ſpecimens from Jacquin, of what he, at one time, ſeems to have confounded with his *S. Columnæ*, Fl. Auſtr. t. 323, as mentioned in Prodr. Fl. Græc. v. 2. 21. Theſe ſpecimens appear a ſmoothiſh variety of *S. Loeſelii*, and bring this ſpecies very near to *Irio*. We now no longer feel any ſcruple reſpecting Columna's t. 268, cited indeed by Linnæus and Willdenow for *S. Loeſelii*, though heedleſsly by the latter for *S. Columnæ* alſo, after Jacquin, and though the hairs on the ſame do not point downward.

S. *orientale*. Oriental Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 40. Ait. n. 40. Prodr. Fl. Græc. n. 1540. (S. Columnæ; Jacq. Auſtr. t. 323. Ait. n. 3.)—Leaves runcinate, downy. Stem without briſtles. Pods erect, thread-ſhaped, on ſhort, thick, ſpreading ſtalks.—Native of the Levant. Dr. Sibthorp had a wild ſpecimen from Zante. According to Jacquin, this ſpecies alſo grows in Auſtria. The *root* is annual. Habit of the *plant* not unlike the two laſt, but the whole herbage is more or leſs denſely clothed with fine cloſe pubeſcence, and the *partial ſtalks*, ſupporting the *pods*, are much ſhorter and thicker than in either. The *leaves* of all three are pinnatifid, not pinnate: the upper ones are more lanceolate and entire in *S. orientale*, than in the others.

S. *obtuſangulum*. Blunt-lobed Wild-rocket. Willd. n. 39. Schleich. Cat. 48. (Eruca, n. 459; Hall. Hiſt. v. 1. 199, excluding all the ſynonyms, except the following. E. inodora; Bauh. Hiſt. v. 2. 862.)—Leaves pinnate or pinnatifid, lyrate, with obtuſe, deeply-toothed lobes. Stem rough with deflexed hairs. Pods erect, on long ſpreading ſtalks.—Native of various parts of Switzerland. We have ſpecimens gathered by the late Mr. Davall near Aigle; where Haller indicates his variety γ, having larger and yellow flowers. We dare not anſwer for all his varieties, any more than for his very incorrect maſs of ſynonyms, but our's is ſurely the plant of Schleicher and Willdenow. The *root* is annual. *Stem* two feet high, leafy, ſomewhat angular, clothed with more minute deflexed hairs than *S. Loeſelii*. *Leaves* well compared by Haller to thoſe of Common Ragwort, *Senecio Jacobæa*, as to their general aſpect. They are often pinnate, not merely pinnatifid; their leaflets, or lobes, nearly uniform, remarkably blunt, moſt toothed backward. *Flowers* numerous, large, denſely corymboſe, on long ſtalks. *Calyx* hairy, ſpreading, as well as the *petals*.

S. *catholicum*. Notch-leaved Wild-rocket. Linn. Mant. 93. Willd. n. 43.—Leaves pinnate; leaflets elliptic-oblong, cut or ſerrated, ſmooth. Stem branched, ſpreading. Pods erect, on long ſpreading ſtalks.—Native of Spain and Portugal, to which the ſpecific name alludes; but this is particularly unfortunate, for we have the ſame plant from Barbary. The *root* is woody, and apparently perennial. *Stem* buſhy, not a foot high, leafy. *Leaves* ſtalked, ſmooth, fleſhy, of about ſix or ſeven, oppoſite or alternate, leaflets, ſharply ſerrated, and ſometimes elegantly cut or pinnatifid, tapering at their baſe, each an inch long, more or leſs. *Flowers* yellow, half the ſize of *S. tenuifolium*, and ſituated like them on corymboſe, finally racemoſe, long, terminal ſtalks. Linnæus, in his herbarium, has confounded a Stockholm ſpecimen of this laſt-mentioned, in which the ſegments of the leaves happen to be jagged, with his real *catholicum*.

Sect. 5. *Leaves oblong, ſcarcely divided.* Nine ſpecies.

S. *barbareæ*. Plantain-leaved Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 41. (S. orientale, barbareæ facie, plantaginis folio; Tourn. Cor. 16.)—Leaves ſimple; the upper ones ovate, toothed, elongated and claſping the ſtem at their baſe; radical ones ſomewhat heart-ſhaped, entire.—Native of the Levant. Linnæus had an incomplete ſpecimen of this very rare plant from profeſſor Burmann. Its general appearance is very like *Eryſimum Barbarea*. The whole herb is ſmooth, and ſaid to be inſipid. *Stem* ſtout, branched, angular and furrowed, leafy. Upper *leaves* gradually ſmaller, and more toothed. *Flowers* ſmall, yellow, terminal, corymboſe, rather numerous. We have ventured to remove this ſpecies from the laſt ſection, as the leaves cannot even be termed pinnatifid.

S. *ſtrictiſſimum*. Spear-leaved Wild-rocket. Linn. Sp. Pl. 922. Willd. n. 46. Ait. n. 15. Prodr. Fl. Græc. n. 1542. Jacq. Auſtr. t. 194. (Arabis a quibuſdam dicta planta; Camer. Epit. 342.)—Leaves ovato-lanceolate, toothed, downy, ſtalked. Corymbs panicled. Pods aſcending.—Native of open, dry, mountainous ſituations, in Germany, Switzerland, and Italy. A hardy perennial, long known in our botanic gardens, flowering from June to Auguſt. The *ſtems* are a yard high, erect, round, or ſlightly angular, wand-like, clothed copiouſly with taper-pointed *leaves*, two or three inches long, dark-green, chiefly downy beneath, occaſionally entire. *Flowers* very abundant and ſhowy, of a golden yellow, in roundiſh, ſimple or compound, corymboſe heads, on long ſtalks, collected at the upper part of the ſtem, into a denſe oblong panicle. *Pods* racemoſe, two inches or more in length, ſlender, ſmooth, thread-ſhaped, two-edged, with a thick, nearly ſeſſile, *ſtigma*.

S. *hiſpanicum*. Spaniſh Wild-rocket. Jacq. Coll. v. 1. 69. Ic. Rar. t. 124. Willd. n. 48.—Leaves lanceolate, ſeſſile, ſmooth, with tooth-like ſerratures. Stem branched, ſpreading. Corymbs racemoſe. Pods cloſe-preſſed.—Native of Spain. Biennial; flowering in May and June, after being protected in the ſtove at Vienna through the winter. The whole *herb* is perfectly ſmooth, a foot and a half high. *Leaves* one or two inches long, bright green, rarely quite entire. *Flowers* deep yellow, ſmaller than the laſt, ſucceeded by long cloſe *cluſters* of crowded or imbricated *pods*, an inch in length.

S. *integrifolium*. Linear Siberian Wild-rocket. Linn. Sp. Pl. 922. Willd. n. 51. (S. n. 38; Gmel. Sib. v. 3. 270. t. 63.)—Leaves linear, entire. Flower-ſtalks hairy, glandular, and viſcid. Pods ſpreading.—In mountainous ſandy parts of Siberia. *Gmelin*. The *root* is ſlender, woody, ſuppoſed by Willdenow to be annual; but of this there is no certain account. *Stem* ſometimes erect, ſometimes procumbent, always hairy and glutinous, round, leafy, more or leſs branched. *Leaves* an inch and a half long, narrow, fleſhy, obtuſe, channelled, ſtalked, deſcribed by Gmelin as ſmooth, which they may perhaps uſually be, but in his ſpecimens before us they are clothed with longiſh ſcattered hairs. *Flowers* much larger than he delineates them, corymboſe, purple or yellow. *Calyx* hairy. *Pods* an inch long, linear, rather aſcending, beſprinkled, like their ſtalks, with prominent glands. *Stigma* very nearly ſeſſile.

S. *indicum*. Indian Wild-rocket. Linn. Sp. Pl. 917. Mant. 93. Willd. n. 52. Burm. Ind. 140.—Leaves ovato-lanceolate, ſtalked, ſerrated, ſmooth; the lower ones ſomewhat lyrate. Stem zigzag, branched, ſpreading. Pods ſpreading, curved upwards.—Native of the Eaſt Indies.

The Malay name on the Linnæan ſpecimen is *Saſavi Sihina*, given by Burmann *Seſuri-china*. He deſcribes the *leaves* as lyrate, of which we trace ſome indications on the ſpecimen, and doubt not the lower ones are ſo. Linnæus has deſcribed this ſame ſpecimen twice, not adverting to his *Sp. Pl.*, when he wrote the *Mantiſſa;* but both are ſufficiently correct. The plant is annual, unknown in our gardens. Its affinity to *S. hiſpanicum*, induces us, with Willdenow, to place it in this ſection, rather than in the firſt, to which Linnæus firſt referred it; but not having ſeen the lower *leaves*, we cannot be poſitive. The *ſtem* is ſlender, ſmooth, and leafy. *Flowers* ſmall, white, ſucceeded by long cluſters of *pods*, each pod hardly an inch in length, nearly cylindrical, obſcurely quadrangular, curved upwards, ſupported by a horizontal ſtalk, a quarter of an inch long. *Stigma* elevated on a ſhort ſtyle. The *pods* have not the ſhort turgid aſpect proper to the firſt ſection of the genus, but accord preciſely with the plants ranged in ſeveral of the latter ſections, whoſe *pods* have more or leſs of a quadrangular ſhape, though two of the angles are often merely indicated by an elevated line along each valve.

Whoever ſhall take the trouble of tracing our remarks through this genus, and examining the other ſpecies, which, for brevity's ſake, we have paſſed over, will ſee how much is ſtill wanting towards a correct generic diſtribution of the whole order. Mr. Brown's, in *Hort. Kew.*, is, notwithſtanding, an able and uſeful attempt at a reform, of which we may ſay more hereafter under the article TETRADYNAMIA. See alſo SILIQUOSÆ and SILICULOSÆ.

Siſymbrium, among the Romans, was one of the ingredients, of which the nuptial garlands were compoſed.

SISYMBRIUM, in *Gardening*, contains a plant of the hardy herbaceous kind, of which the ſpecies cultivated is the common water-creſs (S. naſturtium).

Method of Culture.—This may be effected by parting the roots, or by ſeed. In the firſt method, while the plants are young, a quantity of ſlips ſhould be made with root-fibres to them, and be planted out immediately in a ſhallow, trickling, watery ſituation, when they will readily ſtrike roots, ſeed, and increaſe themſelves.

The ſeed ſhould be collected during the ſummer ſeaſon, and ſown in the ſame places; or, which is better, the plants, with the ripened ſeeds upon them, be thrown into them, where they will ſtrike root, and ſhed their ſeeds for future increaſe.

Theſe plants are in much eſteem as winter and ſpring ſallad herbs.

SISYMBRIUM *Naſturtium*, *Water-Creſſes*, in the *Materia Medica*. The leaves of the water-creſſes have a moderately pungent taſte, and emit a quick penetrating ſmell, like that of muſtard-ſeed, but much weaker. Their pungent matter is taken up both by watery and ſpirituous menſtrua, and accompanies the aqueous juice, which iſſues copiouſly upon expreſſion: it is very volatile, ſo as to ariſe, in great part, in diſtillation, with rectified ſpirit, as well as with water, and almoſt totally to exhale in drying the leaves, or inſpiſſating by the gentleſt heat to the conſiſtence of an extract, either the expreſſed juice, or the watery or ſpirituous tinctures. Both the inſpiſſated juice, and the watery extract, diſcover to the taſte a ſaline impregnation, and in keeping throw up cryſtalline efflorescences to the ſurface. On diſtilling conſiderable quantities of the herb with water, a ſmall proportion of a ſubtile, volatile, very pungent oil is obtained.

Water-creſſes obtain a place in the materia medica for their antiſcorbutic qualities, which have been long very generally acknowledged by phyſicians. They are alſo ſuppoſed to purify the blood and humours, and to open viſceral obſtructions; they are nearly allied to ſcurvy-graſs, but are more mild and pleaſant, and for this reaſon are frequently eaten as ſallad. In the pharmacopeias the juice of this plant is directed with that of ſcurvy-graſs and Seville oranges; and Dr. Cullen has remarked, that the addition of acids renders the juices of the plantæ ſiliquoſæ moſt certainly effectual, by determining them more powerfully to an aceſcent fermentation. Lewis Mat. Med. Woodville Med. Bot.

SISYMBRIUM is alſo a name uſed to expreſs the wild water-mint. See MINT.

SISYRA, among the *Ancients*, a woolly ſkin uſed for a covering to beds.

SISYRINCHIUM, in *Botany*, from συς, *a hog*, and ῥυγχος, *a ſnout*, the name of a bulb, mentioned by Pliny amongſt other bulbs, under various Greek denominations. He relates, after Theophraſtus, book vii. chap. 13. that it is remarkable for increaſing, during winter, in the lower part, which in ſpring becomes contracted, and the upper part is then eatable. Nobody has aſcertained the real σισυῤῥιγχιον of Theophraſtus or Pliny. Botaniſts have applied this appellation according to their fancy, without even pretending to aſcertain whether it alludes to the fondneſs of ſwine for the root, or to any reſemblance in its figure to their ſnout. The *Siſyrinchium* of Columna, *Ecphr.* 328. *t.* 327, is *Ixia Bulbocodium*, in whoſe minute bulb that fanciful author traces ſuch a reſemblance. That of Bauhin and Tournefort is *Iris Siſyrinchium* of Linnæus, a common Greek plant, whoſe bulb increaſes at its ſummit, and is eatable. The name is now retained for a modern genus, of the ſame natural order indeed, but otherwiſe having nothing in common with the plant of the ancients.—Linn. Gen. 465. Schreb. 450. Willd. Sp. Pl. v. 3. 577. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 135. Gawler (Ker) in Sims and Kon. Ann. of Bot. v. 1. 246. Purſh 31. Cavan. Diſſ. 344. Juſſ. 57. Lamarck Illuſtr. t. 569. (Bermudiana; Tourn. t. 208. Gærtn. t. 11.)—Claſs and order, *Monadelphia Triandria.* (*Gynandria Triandria*, Linn.) Nat. Ord. *Enſatæ*, Linn. *Irides*, Juſſ.

Gen. Ch. *Common Sheath* two-edged, of two compreſſed, pointed valves; *partial* ones ſeveral, lanceolate, concave, obtuſe, inferior, ſingle-flowered. Perianth none. *Cor.* ſuperior, of ſix nearly equal, flattiſh, obovate, minutely pointed petals, ſpreading in their upper half; the three alternate exterior ones a little the broadeſt. *Stam.* Filaments three, united half way up, or more, into an obſcurely triangular tube, ſhorter than the corolla, their extremities ſpreading; anthers incumbent, roundiſh. *Piſt.* Germen inferior to the corolla, obovate; ſtyle triangular, the length of the tube; ſtigmas three, erect, ſcarcely tumid, undivided, notched. *Peric.* Capſule obovate, rounded, with three ſlight angles, of three cells, and three valves; the partitions from the centre of each valve. *Seeds* numerous, roundiſh, inſerted in two rows, into each of the partitions.

Eſſ. Ch. Common ſheath of two or more leaves. Calyx none. Petals ſix, nearly equal, flat. Style one. Capſule of three cells, inferior.

1. S. *latifolium*. Broad-leaved Siſyrinchium. Swartz Prodr. 17. Ait. n. 1. (S. palmifolium; Cavan. Diſſ. 348. t. 191. f. 1. Moræa plicata; Willd. Sp. Pl. v. 1. 243. M. palmifolia; Jacq. Ic. Rar. t. 227. Coll. v. 3. 192. Marica plicata; Curt. Mag. t. 655. Bermudiana palmæ folio, radice bulboſâ; Plum. Ic. 35. t. 46. f. 2.)—Stalk round. Sheath many-flowered. Leaves lanceolate, plaited. Native of the Weſt Indies. Cultivated by Miller in 1737. It requires the heat of a ſtove, flowering from

June to Auguſt. The *root* is an ovate bulb, with numerous, very thick and fleſhy, fibres. *Leaves* radical, ſtalked, erect, from one to two feet long, taper-pointed, ſmooth, dark-green, with many longitudinal parallel ribs and plaits. *Stalk* ſolitary, taller than the leaves, very ſmooth and round, bent obliquely, and horizontally at the top, where it bears ſeveral white, inodorous, ſhort-lived *flowers*, hardly an inch broad, accompanied by one ſmall erect leaf. *Anthers* yellow. Linnæus unaccountably confounded this with his true *S. palmifolium*, hereafter deſcribed.

2. S. *elegans*. Yellow Green-ſpotted Siſyrinchium. Willd. n. 1. (Moræa elegans; Jacq. Hort. Schoenbr. v. 1. 6. t. 12.)—Stalk round, ſimple, ſheathed, ſingle-flowered, ſhorter than the ſolitary, linear, decumbent, radical leaf. Petals oblong, acute.—Native of the Cape of Good Hope; flowering in a greenhouſe in May. *Bulbs* the ſize of hazel-nuts, each bearing a long, narrow, decumbent, ribbed, green *leaf*, and an erect *ſtalk*, about a ſpan high, clothed with many large, alternate, ſheathing, rather tumid, *bracteas*. The ſolitary terminal *flower* is full two inches broad, of a bright yellow; the diſk of each of the three outer *petals* marked with a broad green ſpot, highly ornamental. This and the following have not the true compreſſed bivalve *ſheath* of the genus.

3. S. *collinum*. Tawny Siſyrinchium. Cavan. Diſſ. 346. Willd. n. 2. Redout. Liliac. t. 250. (Moræa collina; Thunb. Moræa n. 13. Prodr. 11. Jacq. Ic. Rar. t. 226.)—Stalk round, ſheathed, ſomewhat branched, ſhorter than its linear, pointed, aſcending leaf. Petals oblong, acute. Plentiful on hills at the Cape of Good Hope. Taller than the laſt, with a branched *ſtalk*, bearing about three *flowers*, either of a tawny bluſh-colour, or pale buff, unſpotted. The *leaf*, which grows from the lower part of the ſtalk, ſtands erect, its point drooping over the uppermoſt flower.

4. S. *grandiflorum*. Large-flowered Siſyrinchium. Cavan. Diſſ. 346. t. 192. f. 2. Willd. n. 3.—Stalk round, ſimple, leafy. Sheath with about three flowers. Petals obtuſe, pointleſs. Leaves lanceolate, plaited. Native of Peru. *Bulb* ovate, an inch long, with capillary fibres. *Stem* a foot high, jointed, bearing three or four ſtalked *leaves*, from three to ten inches in length. *Flowers* an inch and a half broad, with obovate *petals*, yellow in the dried ſpecimen. Column of the *ſtamens* meaſuring near an inch. *Cavanilles*.

5. S. *Bermudiana*. Iris-leaved Siſyrinchium. Linn. Sp. Pl. 1353, β. Willd. n. 4. Ait. n. 2. Cavan. Diſſ. 346. t. 192. f. 1. Mill. Illuſtr. t. 73. Redout. Liliac. t. 149. (S. iridioides; Curt. Mag. t. 94. Bermudiana iridis folio, radice fibroſa; Dill. Elth. 48. t. 41. f. 48.)—Stalk two-edged, branched, leafy. Sheath ſhorter than its four flowers. Petals pointed. Leaves ſword-ſhaped.—Native of the Bermuda iſlands. Common in our ſtoves or greenhouſes ſince the time of Dillenius, flowering in ſummer. The *root* is fibrous, perennial. *Plant* erect, about a foot high, ſmooth, with a narrow compreſſed *ſtem* and *leaves*. *Flowers* numerous, an inch wide, dark blue, pale green in the centre, on ſlender partial ſtalks.

6. S. *anceps*. Narrow-leaved Siſyrinchium. Cavan. Diſſ. 345. t. 190. f. 2. Willd. n. 5. Ait. n. 3. Purſh n. 2. (S. Bermudiana; Linn. Sp. Pl. 1353, α. S. gramineum; Curt. Mag. t. 464. Redout. Liliac. t. 282. Bermudiana graminea, flore minore cæruleo; Dill. Elth. 49. t. 41. f. 49.)—Stalk two-edged, winged, unbranched, nearly leafleſs. Sheath unequal, longer than its four flowers. Petals pointed. Leaves ſword-ſhaped.—Native of North America. On dry hills and graſs-plats, from Canada to Carolina, flowering in July and Auguſt. *Purſh*. Hardy in our gardens, but ſeldom preſerved, the *flowers* being ſo much ſmaller and leſs conſpicuous than the former. The whole *plant* is about half the ſize of that ſpecies, of a graſſy aſpect; the *root* crowned with numerous fibres, from the decayed foliage of former ſeaſons.

7. S. *mucronatum*. Pointed-ſheathed Siſyrinchium. Michaux Boreal-Amer. v. 2. 33. Purſh n. 1.—Stalk unbranched, ſomewhat ſetaceous as well as the leaves. Sheath coloured; one valve ending in a long point. In wet meadows of ſhort graſs, in Pennſylvania and Virginia, flowering in June and July. Perennial. *Flowers* of a beautiful blue, ſmaller than the laſt. *Purſh*. The lower part of the *leaves* and the *ſheaths* are purple. *Michaux*.

8. S. *micranthum*. Small-flowered Siſyrinchium. Cavan. Diſſ. 345. t. 191. f. 2. Willd. n. 6.—Stalk two-edged, branched, leafy. Sheath about equal to its two or three flowers. Petals linear, pointed. Leaves channelled.—Gathered by Joſeph de Juſſieu in Peru.—*Root* fibrous. Whole *plant* but three inches high. *Leaves* ſeveral, linear, pointed, concave or channelled, ſheathing, ſhorter than the ſtem. *Sheath* ſomewhat unequal. *Flowers* very ſmall, on capillary ſtalks.

9. S. *californicum*. Yellow Unbranched Siſyrinchium. Ait. n. 4. (Marica californica; Ker in Curt. Mag. t. 983.)—Stalk two-edged, winged, unbranched. Petals obovate, pointleſs. Leaves linear-ſword-ſhaped.—Diſcovered on the coaſt of California, by Mr. Archibald Menzies, who brought ſeeds to England, in 1796. It proves a hardy greenhouſe perennial plant, flowering in ſummer and autumn, and readily propagated, either by ſeed or parting the roots, which, like thoſe of perhaps all the indubitable ſpecies of this genus, unfortunately for the origin of its name, are fibrous. The *ſtalk* is about two feet high, being taller than the *leaves*, though nearly the ſame breadth, and bears but one tuft of numerous *flowers*, from a cloſe *ſheath*, one of whoſe valves riſes ſomewhat above them. The *corolla*, *ſtamens*, and *ſtyle*, are of an uniform bright yellow. Mr. Ker remarks, that the *filaments* are combined in their lower part only.

10. S. *convolutum*. Yellow Branched Siſyrinchium. Redout. Liliac. t. 47.—Stalk two-edged, branched, leafy. Petals ovate, ſcarcely pointed. Leaves linear-ſword-ſhaped.—Said to be a native of the Cape of Good Hope, but for this M. Redouté had no certain authority. It was ſent from Italy to the Paris gardens, and we ſhould not be greatly ſurpriſed, if future enquiries ſhould prove it of American origin. There ſeems very little difference between this ſpecies and the laſt, except its more humble growth, and the *ſtem* being divided or branched, and leafy. Redouté has erroneouſly defined the latter as round, which is corrected in his fifth volume, at *t.* 275. The name alludes to the rolling in of the *petals* as they fade, which is alſo the caſe in *californicum*, and many, if not all, of the other ſpecies.

11. S. *tenuifolium*. Yellow Slender-leaved Siſyrinchium. Redout. Liliac. t. 275.—Stalk compreſſed, branched, ſpreading. Petals ovate, acute. Leaves linear-awlſhaped. Germen hiſpid.—Communicated to the Paris garden by M. Zea, a celebrated Spaniſh botaniſt; ſo that we preſume the plant to be a native of Mexico or Peru, though nothing has been made known as to its origin. This ſpecies agrees with the laſt in its yellow *flowers*, which however appear to be rather more numerous, ſometimes ſix, in each *ſheath*. The *ſtem* and *leaves* are much more ſlender, and hardly ſo tall; the former twice-branched, in a ſpreading manner, the *branches* curved upwards, with an erect leaf or two at each ſubdiviſion. The *germen* is remarkable

for being rough with little glandular hairs, which fall off as the *capſule* ripens. Theſe have not been noticed in any other ſpecies.

12. S. *ixioides*. White New Zealand Siſyrinchium. Forſt. Prodr. 61. (Ferraria ixioides; Willd. Sp. Pl. v. 3. 582. Morea ixioides; Thunb. Moræa n. 7.)—Stalk triangular, branched. Leaves linear, with cartilaginous edges. Outer petals half the ſize of the inner.—Gathered in New Zealand, by Forſter, whoſe ſpecimens are before us. The *root* is woody, furniſhed with very long, tough, zigzag fibres. *Stalks* a ſpan high, nearly leafleſs, branched in the upper part. *Leaves* ſhorter than the ſtalks, erect, flat, linear, a quarter of an inch wide, ſtrongly ſtriated, with a pale cartilaginous edge, but not ſword-ſhaped, as they have no prominence or rib in the middle; their baſes are ſheathing, or equitant. *Partial flower-ſtalks* rigid, widely ſpreading, two, three, or four together, with very ſmall lanceolate *ſheaths* at their origin. *Flowers* about half an inch broad, white, their three outer *petals* ſomewhat coloured, if we may judge from the dried ſpecimen. *Germen* ſmooth. The ſpecimens Thunberg ſaw were taller than our's. The inequality of the *petals* probably led Willdenow to make this plant a *Ferraria*; but it wants the genuine character of that genus, the jagged and curled *corolla*, and has altogether the habit of a true *Siſyrinchium*.

13. S. *palmifolium*. Palm-leaved Siſyrinchium. Linn. Mant. 122, excluding the ſynonym. Willd. n. 7. Ait. n. 5? (Moræa palmifolia; Thunb. Moræa n. 6.)—Stalk two-edged, winged, denſely corymboſe at the ſummit. Leaves ſword-ſhaped, ſtrongly ribbed.—Gathered in Braſil, by father Panegai, who ſent it, with many other new plants, to profeſſor Arduino of Padua, by whom they were tranſmitted to Linnæus. The preſent has all the appearance of a true *Siſyrinchium*, with a fibrous perennial *root*. The *ſtem* is two feet high, erect, unbranched, naked, with two oppoſite leafy wings. *Leaves* equitant, erect, ſhorter than the ſtem, three-quarters of an inch wide, having about five principal ribs in the middle part, and a few finer ones towards the edges. *Flowers* very numerous, in a denſe, corymboſe, compound, terminal *panicle*, two or three inches high, accompanied by one erect ribbed leaf, about the ſame height. *Bracteas* and *ſheaths* near an inch long, ovate, pointed, ſtriated, concave, membranous at the edges. *Flowers* apparently pale, with numerous dark or purpliſh veins; their partial *ſtalks* longer than the ſheaths. *Germen* roundiſh, ſmooth. We are unable to account for the *flowers* having been termed *ſpiked*, unleſs Thunberg has confounded any thing elſe with this rare ſpecies. Linnæus ſays the *ſtyle* is three-cleft more than half way down.

14. S. *ſtriatum*. Yellow Striated Siſyrinchium. Sm. Ic. Pict. t. 9. Willd. n. 8. Ait. n. 6. Redout. Liliac. t. 66. (S. ſpicatum; Cavan. Ic. v. 2. 2. t. 104. Moræa ſertata; Jacq. Hort. Schoenbr. v. 1. 6. t. 11. Marica ſtriata; Ker in Curt. Mag. t. 701.)—Stem much branched, leafy, compreſſed, winged, many-flowered. Flowers faſciculated, with a ſimple ſheath to each.—Native of Mexico; a hardy perennial in our gardens, propagating itſelf ſpontaneouſly by ſeed. The *root* is fibrous, tufted. *Stems* ſeveral, two or three feet high, accompanied by copious, equitant, ſword-ſhaped, ſtriated, glaucous *leaves*, edged with purple, and tinged with ſaffron-colour at their baſe. *Flowers* very numerous, inodorous, forming tufts along the branches, as if whorled, each tuft accompanied by a large concave ſimple *bractea*, and each of the numerous partial ſtalks attended by a ſimple membranous *ſheath*. *Corolla* above an inch wide, expanding in ſunſhine only, when the flowers make a handſome appearance, laſting in ſucceſſion through moſt part of the ſummer. *Petals* obtuſe with a point, ſlightly cohering at the baſe, into the form of a bell, yellow and more or leſs ſpotted within; their upper part widely ſpreading, pale yellow above, ſtriated with purple veins beneath. *Germen* roundiſh, ſmooth. *Capſule* the ſize of a black currant, gibbous. It will be perceived that the ſheaths of this ſpecies do not exactly anſwer to the generic character, yet nothing can be a more genuine *Siſyrinchium*. Much has been done to diſcriminate the genera of this order, and great improvements have been made, but much is ſtill wanting.

SISYRINCHIUM, in *Gardening*, contains plants of the flowery perennial kind, of which the ſpecies cultivated are, the Iris-leaved ſiſyrinchium (S. bermudiana); and the narrow-leaved ſiſyrinchium (S. anceps).

It is obſerved, that the leaves, ſtalks, and flowers of the firſt ſort are three times as large as in the ſecond, and the ſheath incloſes ſix or ſeven flowers; whereas the ſecond has rarely more than two, and theſe expand only for a ſhort time in the morning, while, in the former, they continue open the whole day.

Method of Culture.—Theſe plants may be increaſed by ſeeds and parting the roots: in the former method, the ſeeds of the firſt ſort ſhould be ſown in the autumn, as ſoon as they become ripe, on a border which has an eaſtern aſpect, in drills at three or four inches diſtance, covering them about half an inch with fine mould; they ſhould afterwards be kept clean from weeds with care. They ſucceed beſt in a loamy ſoil in a ſhady ſituation, and where the ground has not been manured. But in the latter ſort the ſeeds ſhould be ſown in pots, in order that they be protected in the green-houſe, or by ſome other means.

The firſt kind affords ornament in the large open borders and clumps of pleaſure-grounds, and the latter among other green-houſe plants of the ſame growth.

SISZEK, in *Geography*, a town of Croatia, at the conflux of the rivers Save and Kulpa, fortified with a wall and moat; captured by the Turks in 1593, and burned by them in 1594, but rebuilt by the Hungarians; 48 miles S. of Varaſdin. N. lat. 45° 38′. E. long. 16° 44′.

SIT, an iſland in the Adriatic. N. lat. 4° 14′. E. long. 15° 24′.

SITA, in *Hindoo Mythology*, is a celebrated incarnation of the goddeſs Lakſhmi, celeſtial conſort of Viſhnu, in his avatara, or deſcent in the form of Rama. In the language of Hindoo fable, ſhe was his ſakti, or energy; and numberleſs poems have been written in honour of her beauty, merits, and deeds. She is one of the moſt popular goddeſſes of the Hindoo Pantheon, and is indeed one of the moſt virtuous and intereſting characters in their puranic or heroic legends. Her hiſtory and that of her lord forms the ſubject of the Ramayana, which epic poem, like the Iliad, is grounded on a rape. (See RAMAYANA.) As noticed in that article, and RAVENA, the carrying off, by the treachery of the tyrant of that name, the virtuous ſpouſe of Rama, rouſed that hero to the mighty deeds neceſſary for her reſcue from the hands of her powerful perſecutor, and celebrated in the fine poem of Valmiki; and, as noticed above, in numberleſs others of ſecondary and minor fame.

The outline of Sita's hiſtory is this. The childleſs raja Janaka, (ſee JANAKA,) having duly propitiated the gods, was led to the benevolent adoption of a female child about five years old, found incloſed in a box by a Brahman in a field. She was called Sita, from *ſit* or *ſet*, meaning a furrow or field; and Janeki, after her adoptive father. Sita, however, means alſo *fair*, and may be thence derived, and is in this ſenſe, of denoting beauty, given alſo to Parvati and Saraſwati, conſorts of the other two divine perſons of the Hindoo triad. She proved to be an incarnation of Lakſhmi, as before noticed; and on attaining maturity was won by Rama, in a conteſt of archery with many ſovereigns, ambitious of obtaining a prize of ſuch incomparable beauty. This ſtory, as it is related in the Ramayana, reminds us of the unyielding bow of Ulyſſes; as none but Rama had power to accompliſh the required and ordained feat; which was piercing the eye of a fiſh whirling on a pin fixed on a high pole; and not looking at the mark, but at its reflection in a veſſel of oil placed on the ground. The ten-headed-twenty-handed tyrant Ravena had previouſly failed. See RAVENA.

Burning with the rage of diſappointed deſire, the tyrant carried her off; and having been in his power, her purity might be poſſibly ſuſpected; ſhe therefore plunged into the flames, where, defended by Pavaka, the regent of fire, her incombuſtibility atteſted her innocency. She was of courſe triumphantly reſtored to her overjoyed huſband. In the Ramayana ſhe is deſcribed as "endued with youth, beauty, goodneſs, ſweetneſs, and prudence; an inſeparable attendant on her lord, as the light on the moon; the beloved ſpouſe of Rama, dear as his own ſoul; formed by divine illuſion, amiable, and adorned with every charm;" and always held forth as an example of conjugal faith and affection.

While confined on the iſland of Lanka, or Ceylon, (ſee thoſe articles,) and perſecuted by the addreſſes of its tyrannical ſovereign, the anguiſh and lamentation of Sita are copious ſubjects of hyperbole for Hindoo poets. Travellers are ſtill ſhewn a lake or pool, called Sita-koonda, ſaid to have originated in the floods of tears ſhed by the captive beauty. This extravaganza was not loſt on our early miſſionaries and travellers. Ceylon being with them the garden of Eden, they find Adam's peak, Adam's bridge, &c. called Rama's by the natives. Eve perſonates Sita, in reſpect to this pool. Sir John Mandeville notices it in his quaint way. Deſcribing Ceylon, he has fair ſcope for his poetical exuberance. "In that iſle is a gret mountayne, and in mydd place of the mount is a gret lake in a full fayre pleyne, and there is gret plentie of watre. And thei of the contrie ſeyn that Adam and Eve wepten upon that mount 100 zeer, when thei weren dryven out of Paradys. And that watre thei ſeyn is of here teres; for ſoe much watre they wepten that made the foreſede lake." Sir John died in 1372. See MANDEVILLE.

A beautiful tree, called Aſoka by Sanſcrit botaniſts, bears a mythological reference to the above fable of Sita. She was confined in a grove of thoſe trees, whoſe name is derived from grief, or lamentation. It is hence, perhaps, alſo ſacred to the god of tears, or the avenging Siva. (See SIVA.) Aſoka, indeed, rather from its privative initial, denotes the abſence of grief, equivalent to grief-diſpeller; thus named poſſibly from its beauty, ſo greatly admired by a poetical and taſteful people.

A numerous ſect of Hindoos adore Sita as Lakſhmi herſelf. It is a branch of the ſect of Ramanuj. (See that article, and SECTS *of Hindoos*, for an account of their peculiarities.) Under the article SAKTI will be found farther thereon. She is ſaid to have borne Rama two ſons, Kuſhi and Lava, who were great orators and minſtrels; but they are ſeldom heard of, except in legends immediately relating to their family.

In our article RAMA we have noticed a Peruvian feſtival, called Ramaſitoa, which, as well as in name (Rama-Sita), remind us of uſages ſtill common among Hindoos. Thoſe diſpoſed to lay ſtreſs on etymological coincidences, may, perhaps, here alſo find the ſource of the much diſputed ſenſe of the word *Paraſiti*. (See Potter's Archæol. Græc. b. ii. c. iii.) This was the name of an order of men among the Greeks, whoſe office ſeems originally to have been the gathering from the huſbandmen the corn allotted for public ſacrifices. Para and Sita are names, in fact, of all the three principal Hindoo goddeſſes, Lakſhmi, Parvati, and Saraſwati (ſee thoſe articles, and PARA,) and may be ſaid to mean *firſt* and *faireſt*, as well as firſt field or fruits. To all theſe, corn and other firſt-fruits of the field are appropriate offerings; the gathering and care of which might give the prieſts the name of Paraſiti. The common appropriation of theſe tithes to their own uſes would naturally in time degrade them and their name in the eſtimation of their flock, who, detecting the impoſtures of prieſtcraft, brought them to their proper level in the ſenſe of the thence derived word Paraſite. See that article.

SITACA, or SITACE, in *Ancient Geography*, a large and well-peopled town of Aſia, in the Perſide, near Babylon, and 15 ſtadia from the Tigris, according to Xenophon. This town was ſituated nearly at an equal diſtance from the Tigris and the Euphrates, N.W. of Seleucia.

SITACAS, a river of Aſia, in the Perſide, which runs into the Perſian gulf, about 800 ſtadia beyond the mount Areon, according to Nearchus.

SITALA, in *Geography*, a river of Mexico, which runs into the Pacific ocean, N. lat. 17° 38′. W. long. 101° 40′.

SITANG, a river of Hindooſtan, one of the branches of the river called Pegu, which runs into the bay of Bengal.

SITANTA, the name of a fabulous mountain, in which is deſcribed the terreſtrial abode of the god Indra, the Hindoo regent of the firmament. (See INDRA.) In the Hindoo Pantheon, the wonderful mountain Meru is deſcribed from the Puranas. (See MERU.) On one of its three peaks is Kailaſa, the Olympus of Siva; and on another is the Swerga, or paradiſe of Indra. But his terreſtrial abode is on Sitanta, a part probably of Meru; and it may be amuſing to ſee in what the delights of Hindoo gods are ſuppoſed, by their ſacred writers, to conſiſt. Sitanta is "ſkirted by a moſt delightful country, well watered, and enlivened by the harmonious noiſe of the black bee and frogs. There, among immenſe caves, is the Kridavana, or place of dalliance of Mahendra; where knowledge and the completion of our wiſhes are fully acknowledged. There is the great foreſt of the Pariyateka-tree of the king of the gods, known through the three worlds; and the whole world ſings his praiſe from the Veda. Such is the place of dalliance of him with a thouſand eyes, or Indra. In this charming grove of Sakra, or Indra, the gods, the danavas, the ſnakes, yakſhas, rakſhas, guhyas or kuveras, gandharvas, live happy; as well as numerous tribes of Upſara, fond of ſport." P. 270. The Gandharvas are celeſtial female choriſters.

The abode of Viſhnu is uſually called *Vaikontha*; which ſee, and SWERGA.

SITAWACA, in *Geography*, a town of the iſland of Ceylon; 44 miles S.S.W. of Candy.

SITCA, a Ruſſian ſettlement on the N.W. coaſt of America, ſomewhat S. of Cadiack, or Kadiak, in the interior of that deep bay to which Vancouver gave the name of Norfolk's ſound. The ſavages in this quarter are of a more lively and ferocious character than thoſe of Cadiack. Inſtead of dozing on the ridges of their houſes, they ſing and dance perpetually; and are both brave and expert in the uſe of fire-arms, with which they are ſupplied by the American traders, who occaſionally reſort to that coaſt. They killed five or ſix of M. Liſianſky's men, in a gallant defence of a kind of rude fort, from which that commander choſe to expel them, that the agents of the Ruſſian Company might occupy the ſpot as a factory. After cannonading it all day, it was found next morning that the natives had deſerted it in the night; and when M. Liſianſky went to take poſſeſſion, he was not a little ſhocked "to find, as in a ſecond maſſacre of innocents, numbers of young children lying together murdered! leſt their cries, if they had been carried along with them, might have led to a diſcovery of the flight of their cruel parents;—a number of dogs had been butchered for the ſame reaſon." They burn their dead, and maſſacre their priſoners. They are extremely muſcular and hardy; and apparently quite inſenſible to pain. One lad, who frequently viſited the navigators, and ſtole whatever he could lay his hands on, was at laſt threatened with the ſcourge, but abſolutely laughed at the menace,—and continued his deriſion and gaiety when under the moſt rigorous diſcipline that a Ruſſian flagellator could apply. They are great beaux withal;—paint their faces of various colours, and work up their hair with a red paſte, and then powder it in a magnificent manner with the fine white down of the ſea-ducks. Their country is obviouſly volcanic. M. Liſianſky climbed up the higheſt mountain on the coaſt, which Vancouver diſtinguiſhed by the name of Mount Edgecumbe, and found the ſummit formed into a huge crater, nearly two miles in circuit, and about three hundred feet deep. It was partly filled with ſnow; and there is no tradition of the volcano having been ſeen in a ſtate of activity. The height he eſtimated at no leſs than 8000 feet.

We ſhall here ſubjoin, from the work now before us, ſome account of the other ſettlement called *Cadiack.* This is a large barren iſland, at the eaſtern extremity of the Aleutian chain; inhabited by about 4000 of the moſt filthy and ſtupid ſavages of which we have any where an account. They are almoſt all covered over with itch and ulcers; and are extremely indolent and torpid. "Their favourite recreation," ſays M. Liſianſky, "after ſleeping, is to ſit on the roofs of their houſes, or on the beach, for hours together, looking at the ſea, and obſerving a profound ſilence, for they never converſe; and I am perſuaded," adds the worthy Muſcovite, "that *the ſimplicity* of their character exceeds that of any other people." Their great paſſion is for ſnuff and amber; and their chief occupation catching whales,—on the blubber of which they fatten luxuriouſly, in a favourable ſeaſon. They have a ſtrange ſuperſtition, which leads them to believe that the poſſeſſion of the dead bodies of any old or famous fiſhers contributes eſſentially to their good luck; and accordingly ſhew conſiderable ſagacity in hunting them up in the caverns and other ſecret places where they have been ſtowed by their relations. Some, ſays M. Liſianſky, have actually accumulated a treaſury of not fewer than twenty ſuch corpſes.

M. Liſianſky obſerves, that the volcanic energy ſeems to be more entire in this than in any other region of the world. In the neighbourhood of Oonalaſhka, which is ſituated about the centre of the Aleutian chain, a new iſland, nearly twenty miles in circumference, has been formed within theſe twenty years. The following is the account of it, which M. Liſianſky collected from eye-witneſſes at Cadiack.

"In the evening of the 26th, while I was alone, writing the memorandums of my journal, a Ruſſian introduced himſelf, who had reſided on the iſland of Oonalaſhka, when a new iſland ſtarted up in its vicinity. I had heard of this phenomenon, and was therefore deſirous to learn what he knew reſpecting it. He ſaid, that about the middle of April 1797, a ſmall iſland was ſeen where no iſland had been ſeen before. That the firſt intimation of its appearance had been brought by ſome Aleutians to Captain's Harbour, who, returning from fiſhing, obſerved a great ſmoke iſſuing out of the ſea; that this was the ſmoke of the volcano, which was then gradually riſing above the ſurface of the ſea, and which in May, 1798, burſt forth with a blaze, that was diſtinctly ſeen from a ſettlement called Macooſhino, on the iſland of Oonalaſhka, at the diſtance of no leſs than forty miles in the north-weſt. This new iſland is tolerably high, and about twenty miles in circumference. It has been remarked, that it has not increaſed in ſize ſince the year 1799; and that no alteration has taken place in its appearance, except that ſome of the higheſt points have been thrown down by violent eruptions." See Liſianſky's Voyage round the World, in the Years 1803, 4, 5, and 6, performed by Order of His Imperial Majeſty Alexander I. Emperor of Ruſſia, &c. 4to. London, 1814.

SITCHEVSK, a town of Ruſſia, in the government of Smolenſk; 96 miles E.N.E. of Smolenſk. N. lat. 55° 34′. E. long. 34° 44′.

SI-TCHUA, a town of the kingdom of Corea; 33 miles N. of Han-tcheou.

SI-TCHUEN, a town of China, of the third rank, in Ho-nan; 55 miles W. of Nan-yang.

SI TE *fecerit ſecurum*, in *Law*, a ſpecies of original writ, called peremptory, which directs the ſheriff to cauſe the defendant to appear in court, without any option given him, provided the plaintiff gives the ſheriff ſecurity effectually to proſecute his claim. This writ is in uſe, where nothing is ſpecifically demanded, but only ſatisfaction in general; to obtain which, and miniſter complete redreſs, the intervention of ſome judicature is neceſſary. Such are writs of treſpaſs, or on the caſe, in which no debt, or other ſpecific thing, is ſued for in certain, but only damages to be aſſeſſed by a jury. See PRÆCIPE.

SITE, or SCITE, *Situs*, denotes the ſituation of a houſe, meſſuage, &c. And ſometimes the ground-plot, or ſpot of earth on which it ſtands.

SITES *of Homeſtalls*, *Yards*, &c. the ſituations proper for them in different caſes. Theſe are very various, according to the nature and kind of the farms for which they are deſigned, as whether they are thoſe of the ſheep, the grazing, the dairying, the hay and graſs, or thoſe of the mixed, arable, and graſs ſort. In each kind there is a great number of different ſuitable requiſites to be provided, which muſt, in a great meaſure, depend upon the ſite itſelf. See FARM-*Yard*, and YARD.

SITE, *Situs*, in *Logic*, one of the predicaments, declaring a ſubject to be ſo and ſo placed.

SITENSKOI, in *Geography*, a town of Ruſſia, in the government of Novgorod, near the Ilmen; 20 miles W.S.W. of Kreitzei.

SITHA, a town of Hindooſtan, in Guzerat; 75 miles N.N.E. of Junagur.

SITHCUNDMAN, in our *Old Writers*, one whoſe province it was to lead the men of a town or pariſh. Leg. Inæ. cap. 56.

Dugdale ſays, that in Warwickſhire the hundreds were formerly called *ſytheſoca*, and that *ſitheſocundman*, and *ſithcundman*, was the chief officer within ſuch a diviſion, *i. e.* the high-conſtable of the hundred.

SITHE. See SCYTHE.

SITHESOCA, in our *Old Writers*, is uſed to denote the diſtrict now called a *hundred*. The word is Saxon, ſignifying a *franchiſe*, or *liberty*.

SITHON, in *Ancient Geography*, a mountain of Thrace.—Alſo, an iſland of the Ægean ſea.

SITHONIA, a part of Thrace, on the Toronæan gulf, in which were the towns of Torone, Galepſus, Sarmyles, Mecyberne, and Olymbe.

SITHONII, a people of Thrace, near the Euxine ſea, among whom Orpheus was born.

SITIA, a town of Spain, which had a voice in the aſſembly of Cordova.

SITICINES, among the Romans, perſons who ſounded a kind of trumpet, having a very mournful tone, at the burying of the dead.

SITJES, in *Geography*, a town of Spain, in the province of Catalonia; 12 miles S.W. of Barcelona.

SITIFIS, in *Ancient Geography*, a town of Mauritania Cæſarienſis, which became the capital of one of the Mauritanias, to which it gave name. See SITIPHA.

SITIGNAK, in *Geography*, one of the Fox iſlands, in the North Pacific ocean. N. lat. 53° 30′. E. long. 117° 14′.

SITINAGUR, a town of Hindooſtan, in Tellingana; 6 miles N. of Indelavoy.

SITIPHA, or SITIFI *Colonia*, *Settaf*, in *Ancient Geography*, a town of Africa, and the metropolis of Mauritania Sitifenſis. It was ſituated in the interior of the country towards the S.E. of Saldæ.

SITIOGOGUS, a river of Aſia, in the Perſide, which ran into the Perſian gulf.

SITODIUM, in *Botany*, Gærtn. v. 1. 344. t. 71, 72, a name originally applied to the genus affording the celebrated bread-fruit, by ſir Joſeph Banks and Dr. Solander, and derived from σῖτος, *bread*, *food*, or *proviſion*. This name has given way to ARTOCARPUS; ſee that article, and RADERMACHIA.

SITOMAGUM, or SITOMAGUS, in *Ancient Geography*, a town of the iſle of Albion, in the country of the Iceni, between Cambretonium and Venta Icenorun, according to Antonine's Itinerary.

SITON, a town of Greece, in Theſſaly.

SITONÆ, Σιτωναι, among the Athenians, officers appointed to lay in corn for the uſe of the city, for which purpoſe the ταμιας της διοικησεως, or the public treaſurer, was to furniſh them with as much money as they had occaſion for. Potter, Archæol. Græc. lib. i. cap. 15. tom. i. p. 83.

SITONE, in *Ancient Geography*, a town of Macedonia, in the vicinity of mount Athos.

SITONES, the name of one of the three principal claſſes of people who inhabited Scandinavia, beyond mount Savos, and bounded by the ſea to the weſt and the ſouth.

SITOPHYLAX, Σιτοφυλαξ, formed from σῖτος, *corn*, and φυλαξ, *keeper*, in *Antiquity*, an Athenian magiſtrate, who had the ſuperintendance of the corn; and was to take care that nobody bought more than was neceſſary for the proviſion of his family.

By the Attic laws, particular perſons were prohibited buying more than fifty meaſures of wheat a man; of thoſe meaſures, we mean, called φορμοι, and the ſitophylax was to look to the obſervation of this law. It was a capital crime to prevaricate in it.

There were fifteen of theſe ſitophylaces; ten for the city, and five for the Piræus.

SITORE, in *Geography*, a town of Hindooſtan, in the province of Tinevelly; 10 miles N. of Palamcotta.

SITPOUR, a town of Hindooſtan, in the ſubah of Moultan, on the Indus; 30 miles N.W. of Moultan.

SITRIGALLY, a town of Hindooſtan, in Myſore; 34 miles N.N.E. of Chitteldroog.

SITTA, the *Nuthatch*, in *Ornithology*, a genus of birds of the order Picæ, of which the generic character is, Bill ſubulate, roundiſh, ſtraight, entire; the upper mandible is a little longer, compreſſed, and angular at the tip; tongue jagged, ſhort, horny at the tip; the noſtrils are ſmall, covered with briſtles; the feet are formed for walking; the hind-toe is long. Gmelin reckons twelve

Species.

* EUROPÆA; European Nuthatch. Cinereous, beneath reddiſh; the tail-feathers black; the four lateral ones beneath are tipt with white. It weighs nearly an ounce; its length is five inches; the bill is ſtrong and ſtraight, and about three-quarters of an inch long; the upper mandible is black, the lower white; the irides hazel; the crown of the head, back, and coverts of the wings, are of a fine blueiſh-grey; a black ſtroke paſſes over the eye from the mouth; the cheeks and chin are white; the breaſt and belly are of a dull orange-colour; the quill-feathers are duſky; the wings underneath are marked with two ſpots, one white, at the root of the exterior quills, the other black, at the joint of the baſtard-wing; the tail conſiſts of twelve feathers, the two middle are grey, the two exterior feathers tipped with grey, then ſucceeds a tranſverſe ſpot, beneath that the reſt is black; the legs are of a pale yellow; the back toe very ſtrong, and the claws large. Such is Mr. Pennant's deſcription of the European nuthatch, who adds, that "this bird runs up and down the bodies of trees like the woodpecker tribe, and feeds not only on inſects but on nuts, of which it lays up a conſiderable quantity, as winter proviſion, in the hollows of trees. It breeds likewiſe in the hollows of trees; and if the entrance be too large, it ſtops up part of it with clay, leaving only room enough for admiſſion. In autumn it begins a chattering noiſe, being ſilent the greater part of the year. This bird makes its neſt of dead leaves, moſtly of the oak, which it heaps together without much order. It lays ſix or ſeven eggs, which are white, ſpotted with ruſt colour, ſo exactly like thoſe of the great titmouſe, that it is almoſt impoſſible to diſtinguiſh them. No perſecution will force this little bird from its habitation, when ſitting: it defends its neſt to the laſt extremity, ſtrikes the invader with its bill and wings, and makes a hiſſing noiſe; and after every effort of defence, will ſuffer itſelf to be taken in hand, rather than quit its poſt."

"The nuthatch," ſays colonel Montague, in his Ornithological Dictionary, "is more expert in climbing than the woodpecker; for it runs in all directions up and down a tree, whereas the other is never obſerved to deſcend: the ſtiff tail of thoſe birds ſupport them in the act of climbing and hacking. The flexible tail of the nuthatch gives it no ſuch advantage, nor does it ſeem to want it; for its moſt favourite poſition, when breaking a nut, is with the head downwards. In autumn it is no uncommon thing to find, in the crevices of the bark of an old tree, a great many broken nut-ſhells, the work of this bird, who repeatedly returns to the ſame ſpot for this purpoſe. When it has fixed the nut firmly in a chink, it turns on all ſides, in order to ſtrike it with the moſt advantage. This, with the common hazel-nut, is a work of ſome labour; but it breaks the filberd with eaſe. In defect of ſuch food, inſects and their larvæ are ſought after among the moſs on trees, and old thatched buildings. It is commonly met with about orchards, and is ſometimes ſeen, in the cider ſeaſon, picking the ſeeds from the refuſe of the preſſed apples. The note is various: in the ſpring it has a remarkably loud ſhrill whiſtle, which ceaſes after incubation; in autumn is a double reiterated cry." There is a variety, called the little nuthatch, which is much ſmaller than the common nuthatch, and of a more noiſy diſpoſition. It reſides in ſimilar ſituations, and is equally ſolitary; aſſociating only with its mate, and attacking any other it may happen to ſee.

Canadensis; Canada Nuthatch. Cinereous, beneath pale rufous; eye-lids white. This is of the ſize of the European ſpecies; the bill is blackiſh; crown of the head, hind part of the neck, and ſhoulders, black; the back and rump are of a light grey; over each eye is a white line; the cheeks are white; larger quill-feathers duſky, with grey edges; breaſt and belly pure white; the two middle tail-feathers are grey, the reſt black, with a white ſpot at the tip; the vent is ferruginous, and the legs are brown. It is, as its ſpecific name imports, a native of Canada, and extends its journies as far ſouth as New York. Mr. Pennant makes it a mere variety of the European nuthatch; but by Linnæus and Latham it is regarded as a diſtinct ſpecies.

Carolinensis; Black-headed Nuthatch. Cinereous, beneath whitiſh; lower part of the belly reddiſh; head and neck above black; lateral tail-feathers white, varied with black. It is a native of the temperate parts of America, and of the iſland of Jamaica.

Jamaicensis; Jamaica Nuthatch. Cinereous, beneath white; crown black; lateral tail-feathers blackiſh, tipped with tranſverſe white lines. This has been deſcribed by ſir Hans Sloane in his Natural Hiſtory of Jamaica. It is of the ſize of the common nuthatch, the length being five inches and a half; the bill nearly an inch long, and black; the head is large, with a black crown. It is, as its ſpecific name imports, a native of the iſland of Jamaica. It is alſo found in many parts of South America, feeding on inſects, and having the character of a ſtupid bird, eaſily ſuffering itſelf to be taken. From the ſize of its head, it is known in Jamaica by the name of loggerhead. There is a variety much leſs.

Pusila; Small Nuthatch. Cinereous, beneath dirty white; the head is brown, with a dirty white ſpot behind; the lateral tail-feathers are black. It inhabits North America, and is ſaid to be found in Carolina throughout the whole year.

Major; Great Nuthatch. Grey, beneath whitiſh; the chin is white; the quill and tail-feathers brown, edged with orange. This is deſcribed by ſir Hans Sloane in the Hiſtory of Jamaica; it is ſeven inches and a half long; the bill is thickeſt in the middle, and curved at the end; the head and back are grey; the under parts are whitiſh; the wings and tail are brown, with orange edges. It is a native of Jamaica, and feeds on worms, inſects, &c.

Nævia; Spotted Nuthatch. Above it is of a lead-colour, beneath glaucous; the chin is white; the wing-coverts are ſpotted with white. This bird is deſcribed by Edwards under the title of wall-creeper of Surinam, who ſays, the bill is long in proportion, ſtraight, ſomewhat compreſſed ſideways, a little hooked at the point, and of a duſky browniſh colour; the head, the hinder ſide of the neck, back, rump, tail, and wings, are of a dark blueiſh-lead colour; all the covert-feathers on the upper ſide of the wings are tipped with white; the inſides of the quills and under ſide of the tail-feathers are aſh-coloured, lighter than they are above; the throat is white; the breaſt, belly, thighs, and coverts beneath the tail, are of a blueiſh-aſh colour, lighter than the upper ſide of the bird; from the throat, as far as the legs, the breaſt is marked with white lines, drawn down the middle of each feather, which end in points; the legs and feet are of a duſky brown colour. The length of this bird is about ſix inches. It is, as its trivial name imports, a native of Surinam.

Surinamensis; Surinam Nuthatch. Reddiſh-cheſnut, beneath it is of a dirty white; middle of the back white; wings and tail black; wing and tail-coverts tipped, and ſecondary quill-feathers edged, with white. This is a very ſmall ſpecies, not much more than three inches in length; the bill is of a duſky brown, and a little curved; the hind-head and neck are marked with oblong black ſpots. It is, as its ſpecific name imports, a native of Surinam.

Caffra; Cape Nuthatch. Body beneath is yellow, above yellow, varied with black; the legs are black. It inhabits the Cape of Good Hope. This was deſcribed by Sparmann, and is by him ſaid to be nine inches in length, with a ſtraight blueiſh-black bill; the front, hind part of the neck, and back, mixed with brown and yellow; cheeks, neck, breaſt, and under parts, are of a duſky yellow, as are alſo the edges and tips of the wing-feathers; the tail is duſky black, beneath olive; the two middle feathers longer than the reſt; the legs are black.

Sinensis; Chineſe Nuthatch. The ſpecific character of this, according to Gmelin, is, that the lower eye-lid is purple. But Dr. Shaw denominates it the ferruginous nuthatch, with black head and neck, white breaſt and abdomen, a red ſpot behind the eye, and another white one. This bird is deſcribed by Latham as ſomething larger than the goldfinch; the bill and head are black; the back is of a deep blueiſh-ferruginous; the throat, breaſt, and belly, are white, but the throat is encompaſſed by a black band, deſcending from the ſides of the head, which is black and creſted; near the eye is a ſmall ſcarlet ſpot, ſucceeded by a large white one; the rump is yellow; the tail blackiſh, with a white tip; the bill and legs are black. It is, as its name denotes, a native of China, where it is ſaid to be much eſteemed on account of the elegance of its colours, and is a frequent ornament on Chineſe papers. "It appears," ſays Dr. Shaw, "to be much allied to the Lanius jocoſus, or red-vented ſhrike, and may perhaps prove, on future inveſtigation, to be no other than the ſame bird."

Longirostra; Long-billed Nuthatch. Blueiſh, beneath pale rufous; primary quill-feathers tipped with brown; the lores are black. This ſpecies is deſcribed by Dr. Latham, and is ſaid to meaſure nine inches; the bill is above an inch long, and black, but the baſe is pale or whitiſh; the crown of the head and whole upper parts of the bird are of a pale blueiſh-grey, but the cheeks and forehead are white, and a black ſtreak paſſes through each eye, along the ſides of the neck; the wings are tipped with brown, and the under parts of the bird are pale tawny; the legs are of a pale brown. It inhabits Batavia.

Chloris; Green Nuthatch. Above green, beneath white; the tail is black, tipped with yellowiſh; the bill is longer than the head, and blackiſh towards the tip: quill-feathers brown, outer edge greeniſh, yellowiſh in the middle, forming a yellowiſh band on the wings; the rump is yellowiſh, and the tail ſhort. It is a native of the Cape of Good Hope, and is of the ſize of the Surinam nuthatch.

SITTACENE, in *Ancient Geography*, a country of Aſia, in Aſſyria, near Suſiana. Ptolemy.

SITTACENI, the name of thoſe people of Aſiatic Sarmatia, who inhabited the vicinity of the Palus Mæotis.

SITTART, in *Geography*, a town of France, in the department of the Roer; 12 miles S. of Ruremond.

SITTEBERIS, in *Ancient Geography*, a town of India, on this ſide of the Ganges. Ptolemy.

SITTENBACH, Alt, in *Geography*, a town of Bavaria, in the territory of Nuremberg; 3 miles W. of Herſbruck.

Sittenbach, *Kirch*, a town of Bavaria, in the territory of Nuremberg; 5 miles N. of Herſbruck.

SITTENSEN, a town of Germany, in the duchy of Verden; 18 miles N.E. of Rottenburg.

SITTER, a river of Switzerland, which riſes in the canton of Appenzell, and joins the Thur, 9 miles W. of St. Gal.

SITTICHENBACH, a town of Saxony; 6 miles N.W. of Querfurt.

SITTICOTE, a town of Hindooſtan, in Dowlatabad; 30 miles S. of Renapur.

SITTINGBOURNE, a poſt and fair-town in a pariſh of the ſame name, hundred of Milton, and county of Kent, England, is ſituated on the high road from London to Canterbury, at the diſtance of 40 miles S.E. from the metropolis, and 13 miles N.E. by E. from Maidſtone. This place is of conſiderable antiquity, and derives its name, by corruption, from the Saxon word "Sædingburna," which ſignifies the village by the bourne or ſtream. Henry V. was entertained here, on his triumphant return from France, by John Northwood, eſq. of Northwood, in a ſtyle of magnificence befitting the royal dignity. Queen Elizabeth incorporated this town by charter, and conferred upon it the privileges of a weekly market and fairs, firſt in the 16th year of her reign, and again in her 41ſt year. By the latter deed, the corporation was conſtituted by the ſtyle of the mayor and jurats, and was inveſted with the right of ſending two members to parliament. Theſe privileges, however, never ſeem to have been exerciſed; and even the market was dropped in a few years; but the fairs are ſtill kept on Whit-monday and the two following days, and on the 10th of October and the four following days.

Sittingbourne chiefly forms one wide ſtreet on the high road, which here deſcends towards the eaſt. The principal ſupport of its inhabitants ariſes from the cuſtom of travellers who paſs through it. The inns are numerous, and ſome of them equal in magnificence to any provincial inn in the kingdom. The church is a ſpacious ſtructure, divided into a nave and two aiſles, a chancel, two chapels, and a tower, which riſes at the weſt end. The whole has been rebuilt, with the exception of the tower, ſince the year 1762, when it was deſtroyed by fire. By that cataſtrophe, moſt of the monuments periſhed; and ſuch of them as were preſerved, were ſo capriciouſly removed, that few of them cover the remains of the perſons they were intended to commemorate. The moſt curious monument remaining is one in the north, or Bayford chapel, which conſiſts of a table-ſlab of Betherſden marble, placed under an obtuſely pointed arch, ornamented with quatrefoil compartments, diſplaying heads, ſhields, fleur-de-lis, &c. and having, in the receſs behind it, the emaciated figure of a female in a winding-ſheet.

Sittingbourne pariſh is of ſmall extent, and contains, according to the parliamentary returns of 1811, 239 houſes, and 1362 inhabitants. Lewis Theobald, who publiſhed two editions of Shakſpeare's plays, with notes, in 1733 and 1740, was a native of this pariſh.

At Bayford, to the north of Sittingbourne, are ſome remains of an ancient intrenchment, ſaid to have been formed by king Alfred, when he came hither to repel the incurſions of the Danes, in the year 893. This place was afterwards the ſcite of a caſtle, which, in the time of Edward I., was the baronial ſeat of Robert de Nottingham, as appears from various deeds ſtill extant, bearing date "Apud caſtellum ſuum de Bayford apud Goodneſton." Haſted's Hiſtory of Kent, vol. vi. 8vo. edit. 1798. Beauties of England and Wales, vol. vii. by E. W. Brayley, 1806.

SITTUKERA, a town of Hindooſtan, in the ſoubah of Moultan; 15 miles from Shawanaz.

SITUA, in *Ancient Geography*, a town of Aſia, in Paphlagonia.

SITUS, in *Geometry* and *Algebra*, denotes the ſituation of lines, ſurfaces, &c.

Wolfius gives us ſome things in geometry, which are not deduced from the common analyſis; particularly, matters depending on the ſitus of lines and figures. M. Leibnitz has even invented a particular kind of analyſis thereon, called *calculus ſitus*.

SITZENBERG, in *Geography*, a town of Auſtria; 10 miles W.S.W. of Tulin.

SITZKOI, a town of Ruſſia, in the government of Olonetz; 12 miles E.S.E. of Ladeinoepole.

SIVA, in *Ancient Geography*, a town of Cappadocia, in the prefecture of Cilicia. Ptolemy.

SIVA, in *Hindoo Mythology*, is a perſonification of one of the three great powers of the deity. Siva is uſually deemed the third perſon in the Hindoo triad, and to repreſent the *deſtructive* energy. A detailed account of this important perſonage would extend itſelf to a hiſtory of the whole Hindoo Pantheon; for he appears in ſuch a variety of forms, and on ſo many occaſions, that ſcarcely a ſtep can be taken in any department whatever of eaſtern ſcience, art, or ſubject of literature, without encountering Siva in ſome of his varied characters. Under the articles SAIVA and VAISHNAVA we have ſtated, that the whole race of Hindoos are divided into thoſe two claſſes, denoting the worſhip of Siva, or of Viſhnu; Brahma, the firſt or creative power, having no worſhippers, or temples. Of this curious fact, ſee under SARASWATI, the name of his conſort. Theſe two comprehenſive claſſes are alſo called Saiva-bakht, and Viſhnu-bakht. See SECTS *of Hindoos*.

As the *deſtructive* energy of the deity, Siva is moſt uſually ſeen; but deſtruction being uſed in the ſenſe of renovation, the character of Siva is that of the renovator, or recreator; aſſociating him in character with Brahma, the producing or creative power. See VEDANTA.

We will try to exhibit, at one view, the variety of relations in which this and the other two members of the Hindoo triad appear; whether they be introduced mythologically, metaphyſically, or philoſophically. All three are ſymbols of the ſun, as he is typical of that great light, as the theologians expreſs it, "whence all proceeded, and to which all muſt return." See O'M.

Brahma	Power	Creation	Matter	The paſt	Earth.
Viſhnu	Wiſdom	Preſervation	Space	The preſent	Water.
Siva	Juſtice	Deſtruction	Time	The future	Fire.

But theſe characters, or attributes, are not excluſively applicable to the three powers, as indicated above. They coaleſce and participate, more or leſs, in ſeveral. An attempt has been made to ſhew in what degree, more particularly, they repreſent their material forms of earth, water, and fire: thus,

Brahma and Siva are Fire, in which Viſhnu	does not participate, or participates but remotely.
Viſhnu and Brahma are Earth, in which Siva	
Siva and Viſhnu are Water, in which Brahma	

As well as affinities, theſe powers have oppoſing properties; conteſts of perſons, in mythological language, and in that of the myſtics, attractions, and love.

The conteſts of theſe powers, or perſons, their quarrels and reconciliations, yield fine occaſions for poetical exuberance. The preſervative and regenerative powers, being in conſtant action, are feigned to have deſcended on earth innumerable times, in divers places, for the inſtruction and benefit, including the ſalutary puniſhment, of mankind.

The wives and children of theſe powers have alſo, like their lords and parents, deſcended and aſſumed a variety of forms on earth, for ſimilar purpoſes. The hiſtory of theſe endleſs incarnations affords ample ſcope for the imagination; and they are worked up by the poets, with wonderful fertility of genius and pomp of language, into a variety of ſublime deſcriptions, interſperſed with theological and moral texts, that at length were received as inſpired productions, and have become the ſtandard of divine truth. See Purana, the title of a ſeries of mythological poems, or rather of poems on every ſubject, under the ſimilitude of mythological adventure.

The wives or conſorts of theſe mythological perſonages are mentioned above. All the Hindoo deities are mated in fable, and their ſpouſes are their powers or active energies, and are called their *Sakti.* See that article.

The Hindoo deities have alſo vehicles aſſigned for the conveyance of themſelves and wives. Theſe are called vahan. The vahan of Siva is a bull, called Nandi. They have likewiſe peculiar ſymbols or attributes: thoſe that more particularly deſignate Siva, his ſakti, or any thing connected with them, are the Linga, or phallus, and the Triſula, or trident. The phallic emblem denotes his preſiding over generation; reminding us of the Jupiter Genitor of weſtern mythologiſts, with whom ſir William Jones identifies the Siva of the Eaſt.

There is yet another attribute of Mahadeva, (a name of Siva,) by which he is too viſibly diſtinguiſhed in the drawings and temples of Bengal. To *deſtroy,* according to the Vedantis of India, the Sufis of Perſia, and many philoſophers of our European ſchools, is only to *generate* and *reproduce* in another form. Hence the god of *deſtruction* preſides over *generation;* as a ſymbol of which he rides on a *white bull.* Can we doubt that the loves and feaſts of Jupiter *Genitor,* (not forgetting the white bull of Europa,) and his extraordinary title of *Lapis,* for which no ſatisfactory reaſon is commonly given, have a connection with the Indian philoſophy and mythology?

The Jupiter Marinus, or Neptune of the Romans, reſembles Mahadeva in his generative character; eſpecially as the Hindoo god is the huſband of Parvati, whoſe relation to the *waters* is evidently marked, by her image being reſtored to them at the concluſion of the great feſtival called Durgotſava. She is known to have attributes exactly ſimilar to thoſe of Venus Marina, whoſe birth from the ſea-foam, and ſplendid riſe from the conch in which ſhe had been cradled, have offered ſo many charming ſubjects for ancient and modern poetry. Diſſ. on the Gods of Greece, Italy, and India. Aſiat. Reſ. vol. i.

Another writer, Mr. Paterſon, in the eighth volume of the ſame work, offers a paſſage deſcriptive of the character and attributes of Siva. "To Siva," he ſays, "are given three eyes, probably to denote his view of the three diviſions of time; the paſt, the preſent, and the future. A creſcent on his forehead, pourtrays the meaſure of time by the phaſes of the moon; a ſerpent forms a necklace to denote the meaſure of time by years; a ſecond necklace, formed of human ſkulls, marks the lapſe and revolutions of ages, and the extinction and ſucceſſion of the generations of mankind. He holds a trident, to ſhew that the great attributes are in him aſſembled and united; in another is a kind of rattle, ſhaped like an hour-glaſs, and I am inclined to think that it was at firſt intended as ſuch, ſince it agrees with the character of the deity; and a ſand *gheri* is mentioned in the Saſtra as a mode of meaſuring time. In the hieroglyphic of Maha Pralaya, or grand conſummation of all things, when time itſelf ſhall be no more, he is repreſented as trodden under foot by Mahakala, or eternity." In this character he is called Kalanteka.

An anonymous writer (Edinburgh Review, N° XXXIV. p. 316.) has offered ſome points of compariſon between the Oſiris of Egypt, the Bacchus of Greece, and the Siva of India, that will ſerve to illuſtrate our obſervations on the latter. "Oſiris was adored in Egypt, and Bacchus in Greece, under the emblem of the phallus. It is under the ſame emblem that he is ſtill venerated in Hindooſtan, and Phalla is one of his names in the dictionary of Amara Singha. The bull was ſacred to him in Egypt. Plutarch aſſures us that ſeveral nations of Greece depict Bacchus with a bull's head; and that when he is invoked by the women of Elis, they pray him to haſten to their relief on the feet of a bull. In India he is often ſeen mounted on a bull; hence one of his Sanſcrit names, Vriſhadwaja, ſignifying, whoſe enſign is a bull. Plutarch informs us, that 'Nilum patrem ac ſervatorem ſuæ regionis, ac defluxum Oſiridis nominant.' The Ganges, in like manner, is fabled by the Hindoos to flow from the treſſes of Siva; hence another of his names, Gangadhara, the ſupporter of the Ganges. We conceive, by the way, that Scaliger and Selden are miſtaken in ſuppoſing that Siris, the Egyptian name of the Nile, is ſynonimous with Oſiris. Siris ſeems to us the Sanſcrit word Saras, a river in general, or *the* river, from its imputed ſuperiority. Iſis is the conſort of Oſiris; Iſa that of Iſwara, or Siva. (See Isa.) The attributes of the goddeſſes might be ſhewn to correſpond as preciſely as thoſe of their lords. The attendants of Iſwara reſemble in their frantic demeanour the furious Bacchants of the god of Naxos. It is remarkable, that many of the appellations by which the Greeks diſtinguiſh Bacchus, are alſo uſed by the Hindoos; but inſtead of applying them to Bagheſa himſelf, the latter give them to his ſon, whilſt both nations have their legends to account for them. Thus, the Greeks named Bacchus, Dimeter, having two mothers; the Hindoos call Skanda, the ſon of Bagheſa, Divimatri, with the ſame ſignification. (See Skanda.) Pyrignes, born from fire, and its equivalent in Sanſcrit, Agnija, are reſpectively Greek and Indian appellatives of Bacchus and Skanda. The title of Thriambus, we are told by Diodorus, was aſſumed by the Greek deity, in his triumph after the conqueſt of India. Tryambo, in like manner, is one of the moſt common appellations of the Indian Bacchus, but we are not aware of its ſignification." See Triambo.

We will ſubjoin what is given in the ſame article, as deſcriptive of Siva, under his name of Iſwara, taken from a copious treatiſe in the Imperial library at Paris, entitled Hyaſiras, but the MS. did not ſpecify from what Purana it was extracted. The Matſya Purana exhibits a full code of ſimilar inſtructions for the guidance of artiſts in pourtraying the various deities of the Hindoo Pantheon. (See Purana.) We premiſe that the name Iſwara means *powerful;* a character denoted by many hands, in the way that many heads denote ſapience.

Iſwara.—Let the arms, ſhoulders, and thighs of Iſwara be brawny and muſcular; his colour that of the beams of the creſcent which decorates his brow; his long hair muſt be knotted in many convolutions; his ſhoulders covered by a tiger's ſkin; his ten arms ornamented with bracelets of ſnakes; pendents hang from his ears: a ſword, a club, a trident, and other weapons, are perceived in his hands. When he appears in the character of the vanquiſher of Tripura, during the conflagration of the city, he has ſixteen arms. (See Tripura.) In the character of Yogeſwara, his aſpect muſt be terrific. See Yogeswara.

Images and pictures of Siva, which, in his various characters, are very common, repreſent him under a great many forms, which our limits will not allow us to enumerate.

In ſome pictures he is ſeen four, ſix, eight, or ten, and as far as ſixteen-handed; and in one character with five faces, thence called *Panchamuki*, which ſee; in ſitting, ſtanding, and dancing attitudes. His attributes are nearly ſimilar to thoſe of his ſakti Parvati. Repreſentations of him, or of his family or ſect, are diſtinguiſhed by the Linga, or cone, the Triſula, or trident, the Paſha, or cord of puniſhment, (ſee PASHA); the third eye, and collar of ſkulls, peculiar to him, his conſort, or family; the moon and Ganga in his hair; a hand drum, ſhaped like an hourglaſs, and called, both in Sanſcrit and Greek, *dindima*, and hence probably the name of Dindimia, and other ſimilar names given to the Grecian *queen of heaven;* and Dindymos, a fabulous mountain conſecrated by the Argonauts to the *mother of the gods;* titles as well of the conſort of the Indian Siva as of the Grecian Jupiter. An antelope, named Saſin, is ſometimes ſeen in Siva's hand, ſuppoſed to have ſome lunar alluſion. (See SASIN.) Theſe are his moſt common attributes. Sometimes he is joined to his ſakti, denoting then a myſtical reunion of the powers of nature.

The fable of Bramah loſing one of his heads has not hitherto been explained. It may probably mean that Bramah, or matter, undergoes curtailment by the deſtructive energy of fire, or Siva. Bramah had once five heads; he has now only four. Perhaps the older coſmogonies may have aſſigned five elements to the componency of matter, which a ſubſequent theory, promulgated by a Saiva, reduced to four. From ſuch ſpeculations originate the fables of mythology. Saying that Siva is Brahma, may mean, that as renovator of forms, he is the recreator; matter being by ſome theories eternal; and creation, as we term it, being merely a periodical reorganization. (See KALPA.) He is the parent and the offspring of Viſhnu. This is ſaid according with the theory or ſect, or the philoſophy or religion, of the relator. (See SECTS *of Hindoos.*) Philoſophically, it may mean that fire, or heat, is the *ſource* of water by its evaporating power, and the *effect* of humidity, through the proceſs of fermentation; either terreſtrial, or by aerial combination. Viſhnu, it will be recollected, is a perſonification of humidity, and we may thus diſcern why Siva and Viſhnu may be mythologically parent and offspring. In the article SRADHA an invocation to fire is given, from the funeral ceremonies of the Hindoos, denoting its renovating property. "Fire! thou was lighted by him; may he therefore be reproduced by thee."

As the patron of aſtronomy, Siva is the Uranus of the Eaſt. He is ſaid to guide the motions of the planet Jupiter, named by the Hindoos VRIHASPATI; ſee that article. He has been already noticed as the ſun, though that luminary, or its regent Surya, is more ſtrikingly aſſignable to a relationſhip with Viſhnu.

As deſtructive fire, that powerful changer of forms, Siva is, in a philoſophical view, more immediately conſidered. Of him in this character, the cone or linga, it is ſaid, is his ſymbol; being the form naturally aſſumed by flame; and the inverted cone, as the figure of water naturally deſcending, is ſymbolical of Viſhnu. A triangle, with its apex upward or downward, is therefore, being conical, the ſymbol of theſe important deities, in their primary characters of fire and water. Sometimes theſe are ſeen combined, and are then myſtically contemplated as the re-union of nature's elements.

The ſectaries of theſe powers, the conſervative and the changing, reſpectively uphold the ſupremacy of that worſhipped ſeverally by each. Siva being more immediately fire, and Viſhnu water, the philoſophical conteſts for ſupremacy, which have, it is related, been carried to the ſad length of theological war, on the parts of the adherents of theſe different doctrines, may remind one of thoſe controverſies, happily extending no farther, carried on in Europe by the parties at length denominated Vulcaniſts and Neptuniſts. The difference is, that in Europe the cauſes of the world's deſtruction by the deluge, and in India, the mode of its reformation at the period called kalpa, after a pralaya, or diſorganization, is the point in diſpute between their reſpective Saivas and Vaiſhnavas; or, in other words, the Vulcaniſts and Neptuniſts. Another inſtance, conſonant to an European diſtinction, may be here noticed. It is ſaid that individuals of the ſect of Saiva are of a more reſerved or ſerious caſt than thoſe of the Vaiſhnava ſect. Gloomy individuals are more diſpoſed to the reverent contemplation of the deſtructive and avenging attributes of the god of juſtice; or in other words, is it that thoſe who adopt ſuch adoration are thence gloomy and dark? Thoſe, on the other hand, who contemplate and adore the deity in his attributes of preſervation and mercy, are of a more cheerful turn. Thus the Saivas are the Calviniſts, the Vaiſhnavas or Baudhas the Lutherans of India.

Siva, as the conſort of Kali, is named Kal or Kala, ſuppoſed to be time; for *kal*, in Sanſcrit and other languages of India, means both yeſterday and to-morrow: it means alſo *black;* and in this character Siva, as well as his ſakti, is painted of that colour, though under other forms, and uſually, white is the colour of Siva. The contemplation of the diſtinctions of day and night; of the light and dark diviſions of the month, a notation of time eſpecially and ſuperſtitiouſly attended to in Hindoo ceremonials; of the ſix months' day and ſix months' night of the gods (occaſioned by the obliquity of the ſun's path); and, laſtly, the contraſt of the viſible creation with eternal night; are ſuppoſed by a writer in the Aſiatic Reſearches (Mr. Paterſon,) to have ſuggeſted the idea of painting Kal white and Kali black. When, however, he appears as Kal, he is ſometimes, as above noticed, alſo black.

To Siva, in his various forms, ſeveral plants are eſteemed ſacred, and are of courſe nouriſhed by his ſectaries; chiefly, it may be preſumed, by women, by the aged, or by Brahmans. A ſhrub named Aſoka, is one ſuppoſed to be pleaſing to Siva. It is deſcribed in the fourth volume of the Aſiatic Reſearches, art. 17, by ſir W. Jones, who ſays, that the vegetable world ſcarcely exhibits a richer ſight than an aſoka tree in full bloom: it is about as high as an ordinary cherry-tree. He expreſſes a hope that its Sanſcrit name may be retained by botaniſts, as it perpetually occurs in the old Indian poems, and in treatiſes on religious rites. It is planted near Siva's temples, and his worſhippers look for efficacy from bathing on a particular day in ſome holy ſtream, and drinking water with buds of the aſoka floating in it. The name means *grief*, or lamentation, and is derived by mythologiſts from the grief of Sita, when confined in a grove of it on Ceylon, by the tyrant Ravena. Sami is the name of another ſhrub ſacred to Siva, connected with which a great deal of enthuſiaſtic extravagance might be pointed out. It may be remarked, that in their ſelection of holy vegetables, the Brahmans have ſhewed conſiderable taſte by ſanctifying thoſe of the moſt lovely ſorts.

One of the Sanſcrit appellations of Siva is the god with a thouſand names. Theſe are given at length in the Padma Purana; and the ſixty-ninth chapter of the Siva Purana is allotted to their enumeration. We propoſed making a ſelection of ſome of them in this article; but it has already been enlarged to its utmoſt allowable extent.

For a further account of Siva and his family, we refer to ſeveral articles that have occurred in this work, and particularly to Kama, Lotos, Matri, Patra, Philosophy *of the Hindoos*, Sects *of Hindoos*, Sagnika, Sankya, and Vedanta.

To this article reference is made from Parvati, of which indeed this may be conſidered as a continuation, and ſeveral errors of the preſs occurring in the latter, we take this opportunity of pointing them out correctively.—In col. 3, line 6, for *cap*, read *cup;* col. 4, l. 35, for *beauty's*, read *brevity's;* col. 5, l. 2, for *Karlikya*, read *Kartikya;* col. 5, l. 9 from the bottom, for *central is*, read *central eye is*.

SIVAN, in *Chronology*, the third month of the Jewiſh eccleſiaſtical year, anſwering to part of our May and June.

SIVAS, in *Geography*, a very large and populous town of Aſiatic Turkey, and capital of a government, to which it gives name, the reſidence of a pacha; anciently called "Sebatte." It is very well watered by the river Caſſalmack, and ſeveral fountains and many clear ſtreams, which run through it. It is ſeated on the W. ſide of a very fertile valley, which is almoſt ſurrounded by lofty mountains, having no opening except where the river runs in and out, through a very narrow channel between two ſteep hills. Here are two ſtone bridges at the diſtance of about a mile from each other. Corn in great abundance grows in this valley, but here is not much fruit, excepting plums, apples, and pears; but of garden vegetables there is plenty. In the middle of the town are ſome very extenſive gardens; and on an artificial hill is an old caſtle, now tumbling into ruins. The houſes in general have a very ordinary appearance, though the neighbourhood furniſhes plenty of good materials for building; a great quantity of unſquared timber being employed to ſupport an immenſe weight of ſtone and clay, with which the houſes are covered. The inhabitants appear to enjoy much liberty; nor are the women confined, as in ſome large cities to the eaſtward. According to Mr. Jackſon's account in his "Journey from India," Sivas is nearly as large as Liverpool, contains as many houſes, and is fully as populous. Although moſt of the private houſes are indifferent ſtructures, many of the public buildings are elegant, and ſome of the monuments very lofty. In the year 1394 this city was taken by Bajazet, and ſoon after by Tamerlane, who deſtroyed the town and made a terrible ſlaughter of the inhabitants. N. lat. 38° 15′. E. long. 37°.

SIVATA, in *Ancient Geography*, a town of Aſia, in Galatia. Ptolemy.

SIVEH, in *Geography*, a town of Perſia, in the province of Mekran, on the Nehenk; 110 miles N.N.E. of Kidge.

SIUEN-TCHEOU, a city of China, of the firſt rank, in Fo-kien. N. lat. 24° 55′. E. long. 118° 29′.

SIVERIE. See Severia.

SIVERS, Henry Jacob, in *Biography*, was born at Lubec in 1709. At the age of 17 he took his degree, as maſter of arts, at Roſtock, and having become ſoon after a teacher in that ſeat of learning, he publiſhed, in 1730, a theſis, "De Fide Salvifica," by which he became advantageouſly known to the literary world. It was, in fact, an anſwer to a book written by Dr. Eric Pontoppidan, entitled "The Bright Mirror of Faith, in which are diſplayed the Marks of the Children of God." Soon after he ſtood candidate for the miniſtry at Lubec; and, on being licenſed, he acquired ſo much popularity, that the churches were crowded wherever he preached. In 1734 he made a tour to Denmark and Sweden, to collect objects for a muſeum of natural hiſtory which he begun to form, and ſettling in the latter, he was invited to be one of the paſtors of the German congregation at Norkoeping; after this he was ordained by biſhop Berzelius, and in 1746 was made one of the court chaplains. In 1747 he obtained the office of paſtor of Trynerym from count Horn, and in the following year he died, in the 50th year of his age. He was a man of conſiderable learning, and poſſeſſed a very fine library. He had likewiſe accumulated a numerous collection of antiquities, natural productions, and various curioſities of art; but in 1737 he had been obliged to ſell to count Charles Gyllenborg the half of his minerals, and a fine cabinet of Roman coins, which the count afterwards bequeathed to the academy of Lund. He carried on an extenſive correſpondence with the celebrated Linnæus, and in 1731 was elected a member of the Academy of Sciences at Berlin. He left behind him a large number of MSS., and he is ſaid to have publiſhed more than a hundred different pieces, the titles of many of which are given in the Gen. Biog.

SIVIDURG, in *Geography*, a town of Hindooſtan, in Myſore; 10 miles E. of Anantpour.

SIUM, in *Botany*, an old Latin name, *σιον* of Dioſcorides, of whoſe etymology nothing plauſible has occurred to us, except the opinion of De Theis, who deduces the word from the Celtic *ſiw*, water:—the plant thus called by Dioſcorides, and every other writer, being an aquatic, of a ſmall ſtature, ſucculent, and aromatic, with parſley-like leaves, as deſcribed in his work. Such is the *Sium* of modern botaniſts, as to moſt of its ſpecies; but their medical qualities do not well anſwer to the report of this old writer, the root eſpecially being eſteemed highly dangerous, like the generality of umbelliferous plants, that grow in water; nor ſhould we truſt to the herbage, either "recent or boiled, to break down and expel *calculi*, to promote urine or child-birth, or to cure the dyſentery."—Linn. Gen. 138. Schreb. 188. Willd. Sp. Pl. v. 1. 1431. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 312. Prodr. Fl. Græc. Sibth. v. 1. 194. Ait. Hort. Kew. v. 2. 144. Purſh 194. Juſſ. 222. Lamarck Illuſtr. t. 197. Gærtn. t. 23.—Claſs and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*, Linn. *Umbelliferæ*, Juſſ.

Gen. Ch. *General Umbel* various in different ſpecies; *partial* ſpreading, flat. *General Involucrum* reflexed, of numerous lanceolate leaves, ſhorter than the umbel; *partial* of many ſmall linear leaves. *Perianth* ſcarcely diſcernible. *Cor. Univerſal* uniform; flowers all fertile; *partial* of five equal petals, rendered heart-ſhaped by their inflexed points. *Stam.* Filaments five, ſimple; anthers ſimple. *Piſt.* Germen minute, inferior; ſtyles two, reflexed; ſtigmas obtuſe. *Peric.* Fruit roundiſh-ovate, compreſſed, ſmall, ſtriated, ſeparable into two parts. *Seeds* two, nearly ovate, convex and ſtriated on the outer ſide, flat on the other.

Eſſ. Ch. Fruit nearly ovate, compreſſed, ſtriated. General and partial involucrum of many leaves. Petals heart-ſhaped, uniform.

1. S. *filifolium*. Thread-leaved Water-parſnep. Thunb. Prodr. 50. Willd. n. 1. ("Conium tenuifolium; Vahl Symb. v. 3. 49.")—"Radical and ſtem-leaves ſimple, thread-ſhaped. Involucrum elongated."—Native of the Cape of Good Hope. We know nothing further about this ſpecies.

2. S. *latifolium*. Broad-leaved Water-parſnep. Linn. Sp. Pl. 361. Willd. n. 2. Fl. Brit. n. 1. Engl. Bot. t. 204. Fl. Dan. t. 246. Jacq. Auſtr. t. 66. (Sium; Rivin. Pentap. Irr. t. 78. S. majus latifolium; Ger. Em. 256.)—Leaves pinnate; leaflets oblong-lanceolate, equally ſerrated.—Native of rivulets, ditches, and watery ground, in the north of Europe; rather common in England, flowering in July and Auguſt. *Root* perennial, of many long, thick, whorled fibres, from the lower joints of the ſtem, by

which the plant in ſome degree creeps along the muddy bottoms of pools and ditches. *Stem* erect, angular, hollow, leafy, ſmooth, ſcarcely branched. *Leaves* alternate, of about three pair of oblong, ſeſſile, ſmooth leaflets, beſides a terminal, ſtalked, rather longer one; all acute, neatly ſerrated, varying in breadth; thoſe under water are liable to be finely divided. *Umbels* large, flattiſh, white, erect, ſolitary, terminal and lateral. *Involucral leaves* widely ſpreading, lanceolate, white-edged, ſometimes lobed, often ſerrated. *Calyx* of five ſmall teeth. *Petals* ſometimes ſlightly unequal in ſize, as is nearly univerſal in this tribe. The whole *herb* is acrid, and the *roots* eſpecially are reckoned poiſonous. This ſpecies does not appear to be a native of Greece, nor to have been known to Dioſcorides.

3. S. *anguſtifolium*. Narrow-leaved Water-parſnep. Linn. Sp. Pl. 1672. Willd. n. 3. Fl. Brit. n. 2. Engl. Bot. t. 139. Prodr. Fl. Græc. n. 674. Jacq. Auſtr. t. 67. (S. nodiflorum; Fl. Dan. t. 247. S. erectum; Hudſ. ed. 1. 103. S. minus; Rivin. Pentap. Irr. t. 79. S. majus anguſtifolium; Ger. Em. 256.)—Leaves pinnate; leaflets irregularly lobed and ſerrated. Umbels ſtalked, oppoſite to the leaves. Stem erect.—Native of rivulets and ditches in Germany, England, France, and the ſouth of Europe. Dr. Sibthorp found it in Greece; and it is more common with us than the preceding, flowering about July or Auguſt. The perennial *root* creeps to a conſiderable extent. The *herb* is of a ſmaller more delicate habit than the laſt, and known by the more unequal inciſions of its *leaves*, at leaſt the upper ones. The *leaflets* of the radical foliage are ſomewhat heart-ſhaped, their edges regularly ſerrated, and the lower pair diſtant from the next. *Umbels* ſolitary, each on a lateral ſtalk, ſhorter than the oppoſite leaf. Leaves of the general *involucrum* drooping, often cut or pinnatifid, often entire. *Calyx* of five hardly viſible teeth.

4. S. *nodiflorum*. Procumbent Water-parſnep. Linn. Sp. Pl. 361. Willd. n. 4. Fl. Brit. n. 3. Engl. Bot. t. 639 Prodr. Fl. Græc. n. 675. Woodv. Med. Bot. t. 182. (S. aquaticum repens et procumbens, ad alas floridum; Moriſ. ſect. 9. t. 5. f. 3.)—Leaves pinnate; leaflets ovate, equally ſerrated. Umbels ſeſſile, oppoſite to the leaves. Stem procumbent.—Frequent in ditches and rivulets, throughout Europe, from Sweden to Greece, flowering in ſummer. Dr. Sibthorp obſerving this ſpecies abundantly in all the waters of the laſt-mentioned country, concludes it, with great probability, to be the real σιον of Dioſcorides, as anſwering well to his deſcription, and being called νεροσέλινον, or water-parſley, by the modern Greeks. The *root* is perennial and creeping. *Stems* procumbent or floating, branched, bearing a nearly ſeſſile greeniſh-white *umbel*, oppoſite to each leaf. The *leaflets* are ſomewhat heart-ſhaped at the baſe, acute, neatly and equally ſerrated, from five to nine in each leaf; the terminal one occaſionally confluent with the next. *General involucrum* of one leaf, and often wanting; *partial* of ſeveral ovate ones. *Calyx* ſcarcely perceptible. The qualities of this ſpecies are probably milder than the two former, inſomuch that three large ſpoonfuls, mixed with milk, have been given twice a day, to cure cutaneous diſorders; and this anſwers to the account given by Dioſcorides, better than any thing we know of the reſt of the genus.

5. S. *repens*. Creeping Water-parſnep. Linn. Suppl. 181. Willd. n. 5. Fl. Brit. n. 4. Engl. Bot. t. 1431. Jacq. Auſtr. t. 260.—Leaves pinnate; leaflets roundiſh, with deep tooth-like ſegments. Umbels ſtalked, oppoſite to the leaves. Stem creeping.—Native of moiſt paſtures, and watery turfy bogs, in Bohemia, Auſtria, Scotland, and England, flowering from June to Auguſt. This is a much ſmaller plant than the laſt, growing on wet ground, but not floating in water. The *ſtems* are quite proſtrate, throwing out many radicles. *Leaflets* fewer, with broad notches, not fine ſerratures. *Umbels* more ſtalked, and whiter. *General involucrum*, as well as the *partial*, of ſeveral ribbed leaves. *Calyx* obſolete.

6. S. *Siſarum*. Skirret. Linn. Sp. Pl. 361. Willd. n. 6. Ait. n. 5. (Siſarum; Ger. Em. 1026. Siſer primum; Matth. Valgr. v. 1. 402. Sju ſjin, vulgò Niſji, &c.; Kæmpf. Am. Exot. 818. t. 819. See Dryandr. in Tr. of Linn. Soc. v. 2. 228.)—Lower leaves pinnate; upper ternate; all ſharply ſerrated. Umbels terminal.—Native of China. Cultivated, time out of mind, in Europe, for the ſake of its perennial, fleſhy, oblong, eſculent roots, formerly reputed to poſſeſs an exciting quality. This notion perhaps originated with the Chineſe; and that knaviſh nation ſeems, as Mr. Dryander firſt remarked, to have impoſed upon the Japaneſe with theſe roots, for the true Ginſeng of Tartary, or *Panax quinquefolia* of Linnæus, which latter ſeems to be *S. Ninſi* of Thunberg. One may be as efficacious as the other, nor would a practitioner, of any deſcription, now perhaps confide in either. The *herb* of the Skirret is twelve or eighteen inches high, erect, branched, leafy. *Lower* leaves of five or ſeven leaflets; *upper* of three; all copiouſly, neatly, and ſharply ſerrated; the lowermoſt ſerratures often much the largeſt, or deepeſt, and ſomewhat ſpreading. *Umbels* at the tops of the branches, white, rather ſmall, with few or no leaves in the *general involucrum*, but ſeveral linear or ſetaceous ones in the *partial*.—*Sium Ninſi*, Linn. Sp. Pl. 361, having been entirely adopted from Kæmpfer's figure of the preſent, that ſpecies falls to the ground; nor is it entitled to rank even as a variety, though marked as ſuch by Willdenow.

7. S. *rigidius*. Virginian Water-parſnep. Linn. Sp. Pl. 362. Willd. n. 7. Ait. n. 6. Purſh n. 1. (Oenanthe maxima virginiana, pæoniæ fœminæ foliis; Moriſ. ſect. 9. t. 7. f. 1.)—Leaves pinnate; leaflets lanceolate, very nearly entire.—“In wet meadows, from Pennſylvania to Virginia, flowering in July and Auguſt. *Flowers* ſmall. This and the following, *S. lineare*, are conſidered as very poiſonous plants, eſpecially to horned cattle, and every farmer who knows their bad qualities is buſily employed to deſtroy them.” *Purſh*. The *roots*, and general habit, of this ſpecies bear conſiderable reſemblance to the laſt; but the *leaflets* are more numerous, narrower, tapering at each end, and either quite entire, or with two or three broad notches only, here and there, in the lower *leaves*. The *umbels* are thrice the ſize of *S. Siſarum*, but, like them, are accompanied by only a ſlight general *involucrum*, nor are the partial ones much more conſiderable.

8. S. *lineare*. Linear Water-parſnep. Michaux Boreal-Amer. v. 1. 167. Purſh n. 2. (S. ſuave; Walter Carol. 115.)—“Leaves pinnate, leaflets elongated, linear, or ſlightly lanceolate, rather diſtantly ſerrated. General involucrum of few leaves; partial of many linear ones. Umbel with ſhort rays.”—In wet meadows, and by the ſides of ditches, from Canada to Pennſylvania, flowering in July; perennial. *Purſh*.

9. S. *longifolium*. Long-leaved Water-parſnep. Purſh n. 3.—“Leaves pinnate; leaflets of the lower ones very long, linear, falcate, ſparingly toothed. Stem ſlightly leafy; naked above. Umbels uſually in pairs, with ſcarcely any involucrum.”—In the ditches and bogs of New Jerſey, flowering in Auguſt.—Very ſlender, perennial. *Purſh*.

10. S. *japonicum*. Japaneſe Water-parſnep. Thunb. Jap. 118. Willd. n. 8.—Leaves pinnate; leaflets of the lower ones oblong or ovate, variouſly cut; of the upper

lanceolate, entire. Umbels terminal.—Native of Japan, flowering in June. The inhabitants call it *Saiko*, or *Mits Suba Seri.* The *ſtem* is erect, zig-zag, branched at the upper part. *Leaves* ſmooth, the lower ones very large, with ſpreading variouſly ſhaped *leaflets,* which are either ovate or oblong, undivided or cut; the upper *leaves* minute. *Umbels* terminating the branches. *Thunb.*

11. S. *Falcaria.* Decurrent Water-parſnep. Linn. Sp. Pl. 362. Willd. n. 9. Ait. n. 7. Prodr. Fl. Græc. n. 676. Jacq. Auſtr. t. 257. (S. n. 782; Hall. Hiſt. v. 1. 347. Falcaria; Rivin. Pentap. Irr. t. 48. Eryngium montanum; Ger. Em. 1164. Ammi perenne repens, &c.; Moriſ. ſect. 9. t. 8. f. 1.)—Leaflets linear, decurrent, confluent, finely ſerrated.—Native of Germany, Flanders, Switzerland, France, Greece, and Aſia Minor; a hardy perennial, kept chiefly in botanic gardens, flowering in July and Auguſt. The *root* is long and cylindrical, white, friable when dried, ſaid to reſemble Eryngo in its ſweetiſh, aromatic, rather acrid, flavour. *Herb* rigid, ſmooth, two or three feet high. *Stem* round, leafy, much branched, terminating in numerous ſlender *umbels* of many rays, with ſmall white *flowers.* The general and partial *involucral leaves* are numerous, long, and very narrow. The radical *leaves* have long ſtalks; the reſt ſhorter more ſheathing ones; all are rigid, ſmooth, ternate in the firſt inſtance; the middle leaflet ternate; the lateral ones binate; the external edge of each lateral leaflet ſtrongly decurrent.

12. S. *verticillatum.* Whorled Water-parſnep. Fl. Brit. n. 5. Roth. Germ. v. 2. p. 1. 336. (Siſon verticillatum; Linn. Sp. Pl. 363. Willd. Sp. Pl. v. 1. 1437. Ait. Hort. Kew. v. 2. 146. Lightf. Scot. 1096. t. 35. Engl. Bot. t. 395. Oenanthe millefolii paluſtris foliis; Moriſ. ſect. 9. t. 7. f. 10. Daucus pratenſis; Dalech. Hiſt. 718.)—Leaflets in numerous, capillary, whorl-like ſegments.—Native of wet ſalt-marſhes. Plentiful in the weſtern parts of Scotland and Wales; found at Killarney, and in the county of Kerry, Ireland, in 1805, by Mr. J. T. Mackay. It is alſo reported to grow in France, the Pyrenées, and ſome parts of Germany. Dr. Roth had, unknown to us, foreſtalled us in transferring this curious ſpecies to *Sium,* before the publication of Flor. Brit. though he had never ſeen a ſpecimen. Of the propriety of this alteration we have no doubt, the *umbels* being of numerous rays, with many leaves in their general as well as partial *involucrum,* and the *petals* heart-ſhaped. The plant is perennial, flowering in July and Auguſt. *Root* of ſeveral fleſhy tapering knobs. *Stem* eighteen inches high, erect, ſmooth, ſcarcely branched, and ſlightly leafy. *Leaves* numerous, chiefly radical, pinnate, of many pairs of deeply-cut, radiating, plumoſe *leaflets,* ſpreading, ſo as to ſeem whorled. *Petals* white, uniform, and nearly equal. *Involucral leaves* deflexed, ovate; five or ſix to the general *umbel,* more to each partial one. *Calyx* hardly viſible. *Fruit* roundiſh-ovate, compreſſed.

13. S. *grandiflorum.* Large-flowered Cape Water-parſnep. Thunb. Prodr. 50. Willd. n. 10.—"Leaves doubly pinnate; leaflets roundiſh, with tooth-like ſegments."—Found by Thunberg, at the Cape of Good Hope.

14. S. *paniculatum.* Panicled Cape Water-parſnep.—Thunb. Prodr. 51. Willd. n. 11.—"Leaves doubly pinnate; leaflets linear, pinnatifid."—From the ſame country.

15. S. *patulum.* Diffuſe Cape Water-parſnep. Thunb. Prodr. 51. Willd. n. 12.—"Leaves doubly pinnate; leaflets three-cleft. Branches diffuſe."—From the ſame country.

16. S. *græcum.* Greek Water-parſnep. Linn. Sp. Pl. 362. Willd. n. 13. (Liguſticum græcum, apii folio; Tourn. Cor. 23.)—"Leaves doubly pinnate; leaflets lanceolate, ſerrated; the uppermoſt confluent."—Native of Greece, according to Tournefort; but we have met with nothing referrible to this ſpecies among Dr. Sibthorp's ſpecimens, drawings, or catalogues, nor have we ſeen any ſpecimen of the authentic plant. Willdenow, from whom we have taken the ſpecific character, ſays the *flowers* are yellow.

17. S. *decumbens.* Decumbent Water-parſnep. Thunb. Japon. 118. Willd. n. 14.—"Leaves doubly pinnate; leaflets three-cleft. Stem decumbent."—Gathered by Thunberg in Japan, where it is known by the name of *Jingoſaku,* and flowers in March. The *ſtem* is ſmall, decumbent. *Leaves* radical, on long ſtalks, ſmooth. *Umbel* terminal, ſcarcely compound. *Seeds* ovate, obtuſe, ſtriated, ſmooth, crowned with the permanent ſtyles. *Thunberg.*—By the deſcription, we ſuſpect this may be more properly a ſpecies of *Hydrocotyle,* but without ſeeing a ſpecimen, we dare not determine.

18. S. *ſiculum.* Sicilian Water-parſnep. Linn. Sp. Pl. 362. Willd. n. 15. Ait. n. 8. Jacq. Hort. Vind. v. 2. 62. t. 133. (Dauco ſiciliano, con foglie di paſtinaca; Zanon. Iſt. 78. t. 30.)—Leaves ſtrongly ſerrated, doubly pinnate; the lower and uppermoſt ternate. Umbels terminal, ſtalked; partial ones very unequal.—Native of Sicily. A hardy perennial, flowering in July and Auguſt. The *ſtem* is variouſly branched, erect, leafy, about two feet high, round, ſolid, ſmooth. *Leaves* ſmooth and ſhining; their *leaflets* more or leſs ovate, acute, copiouſly, deeply, and acutely ſerrated, ſeſſile. General and partial *involucrum* of many linear deflexed leaves. *Flowers* yellow; in ſome of the partial umbels very few, perhaps ſolitary. *Germen* oblong. The genus of this ſpecies is rather doubtful, if we attend to its habit; and yet we know not how, by the characters, to refer it elſewhere.

19. S. *aſperum.* Rough Cape Water-parſnep. Thunb. Prodr. 51. Willd. n. 16.—"Leaves triply pinnate. General and partial flower-ſtalks rough."—Found by Thunberg at the Cape, as well as the two following. We have no information concerning any of them, beſides what his *Prodromus* affords.

20. S. *hiſpidum.* Hiſpid Cape Water-parſnep. Thunb. Prodr. 51. Willd. n. 17.—"Leaves triply pinnate. Footſtalks and flower-ſtalks rough."

21. S. *villoſum.* Villous Cape Water-parſnep. Thunb. Prodr. 51. Willd. n. 18.—"Leaves triply pinnatifid; ſegments ovate, deeply ſerrated, villous."

Sium, in *Gardening,* contains a plant of the hardy, herbaceous, eſculent kind, of which the ſpecies cultivated is the ſkirret (S. ſiſarum).

This plant was formerly much cultivated for the roots, which were eaten boiled and ſtewed with butter, pepper, and ſalt; or rolled in flour and fried; or elſe cold, with oil and vinegar, being firſt prepared by boiling.

Method of Culture.—It may be raiſed either by ſeeds or ſlips from the roots, but the firſt is the beſt method, as in the latter mode the roots are apt to become ſticky: the ſeeds ſhould be ſown about the beginning of April, either in broadcaſt over the ſurface, or in drills, the ground being previouſly well dug to a good depth; light and rather moiſt land being choſen for the purpoſe. The plants moſtly appear in five or ſix weeks, and when they can be ſufficiently diſtinguiſhed by their leaves, the ground ſhould be well hoed over, in the ſame manner as for carrots, the plants being properly thinned out to the diſtance of five or ſix inches. The hoeing ſhould be repeated as often as neceſſary, in dry weather. And in the autumn, when the leaves begin to decay, the roots will be fit for uſe, and will continue ſo till the ſpring.

But in the offset method, the old plants ſhould be dug up in the ſpring before they begin to ſhoot, the ſide ſhoots being then ſlipped off with an eye or bud to each, planting them in rows a foot apart, and four or five inches diſtant in the rows: they ſhould afterwards be cultivated as the others.

Theſe roots are prepared, as has been ſeen, by boiling, and eaten in the ſame manner as above, or as carrots and parſneps. They are wholeſome, but not held in ſuch requeſt as formerly was the caſe.

Sium *Nodiflorum*, Procumbent Water-parſnep, in the *Materia Medica*. This plant has been omitted by the London College, in the laſt edition of its Pharmacopeia, and not, it is thought, without reaſon, as its pretenſions even to the character of an antiſcorbutic require confirmation.

SIUMPOUR, in *Geography*, a town of Hindooſtan, in Bahar; 25 miles E.S.E. of Doeſa.

SIUN, a river of China, which runs into the Han river, near Siun-yam, in Chen-ſi.

SIUNDO, a town of Sweden, in the province of Nyland; 25 miles W. of Helſingfors.

SIUNISONG, a town of Corea, near the ſea; 38 miles W.N.W. of Hoang-tcheou.

SIUN-YAM, a town of China, of the third rank, in Chen-ſi; 20 miles E.N.E. of Hing-ngan.

SIUPH, in *Ancient Geography*, a town of Egypt, in the Saitic nome; the native place of king Amaſis, according to Herodotus.

SIUR, a port of Africa Propria, in the gulf of Numidia, between the Leſſer Collops, and near the promontory of Hippus, according to Ptolemy.

SIVRAY, in *Geography*. See Civray.

SIVREY-*ſur-Meuſe*, a town of France, in the department of the Meuſe; 3 miles W. of Verdun.

SIUT, Siout, or, as it is often called, *Aſſiût*, a town or city of Upper Egypt, and now the moſt conſiderable. This character formerly belonged to Girgé, which is ſtill a place of note, but the character of pre-eminence belongs to Aſſiût. It is ſituated within land a few miles W. of the Nile, on an artificial eminence. The ſcite of this ancient city ſeems to have been either Antopolis, as Pococke thinks, or more probably, as Strabo intimates, Lycopolis. It is a large, populous, and well-built town; and the manner in which the water is conducted round it is worthy of notice. A canal, dug probably from an early period, parallel to the Nile, in this part of the country waſhes the foot of the mountains which are near to Aſſiût, and having ſurrounded that city, and the adjacent villages, deſcends again into the river. The water, however, is not admitted into it except at a certain period of its increaſe, and then it overflows all the ſurrounding lands, and Aſſiût only communicates with the Nile by a road artificially raiſed above the common level, which leads down to the port where the boats reſort, and are laden and diſcharged; and alſo by two bridges, the one leading to this road, and the other towards the mountains. This city has increaſed in population within a few years by the good government of Soliman Bey, who has alſo adorned it by planting many trees. Aſſiût was formerly known to the Arabic writers by the name of "Haut-e-Sultan," the king's fiſh, or fiſh-pond. The reaſon of the appellation is not aſcertained, probably it took its riſe from its having been appointed to ſupply the king's table with fiſh. In the mountain above Aſſiût are ſeveral remarkable caverns, very ſpacious, and adorned with hieroglyphics and emblematical figures. Some appear to have been ſepulchral, as they contain fragments of the jars, in which were depoſited not only the ibis, but cats, dogs, and other animals, whether conſidered as ſacred, or ſlain to attend their maſter or miſtreſs in the other world. In one of theſe caverns, beſides the entrance, there are three chambers hewn in the rock, which is free-ſtone, one ſixty feet by thirty; another, ſixty by twenty-ſix; a third, twenty-ſix by twenty-five. Further up the mountains there are caverns more ſpacious even than theſe. Other cavities have been made by removing the ſtone for the purpoſes of building; but they have been afterwards appropriated to various purpoſes; ſome for ſepulture, as we may conclude from the jars, curiouſly ſtopped with bitumen, and others either for religious retirement in a Chriſtian age, or for ſummer retreats, as they are expoſed to the north, and very cool.

Large quantities of fine flax are cultivated in the vicinity of Siout: this commodity and wheat are tranſported from Upper to Lower Egypt. Salt and other articles are brought in return. From Mecca, by way of Coſſeir, are imported Indian goods; and the European articles of broad-cloth, tin, &c. are here rarely ſeen. The Soudan caravans form a chief ſupport of Aſſiût, which ſerves to them as a midway ſtation. They aſſembled in their way to Sennaar, here, and at Manfalout, under the protection of a bey: they then paſſed nearly ſouth-weſt into the ſandy deſart of Libya, to El-wah, the Oaſis Magna of antiquity, and ſo into the great deſart of Selima. Aſſiût is regarded as the capital of Middle Egypt, and its population exceeds that of all the towns to the ſouth of Cairo. Mr. Browne inclines to eſtimate the inhabitants at no leſs than 25,000. The "ſenjiak," or bey of Saïd, divides the year of his office between Aſſiût and Girgé: the internal government conſiſts of the cadi, aſſiſted by other civil officers; and five caſhefs, moſtly appointed by Soliman Bey, conſtantly reſide there. It is the ſeat of a Coptic biſhop, but the Copts are not very numerous; the people being chiefly Mahometans. Proviſions are conſiderably cheaper at Aſſiût than at Cairo. Manfalout is at no great diſtance from Aſſiût: this is a city of conſiderable extent and population. Between theſe two cities ſtands Ben-Ali, a populous town. Theſe three places conſtitute, with Girgé, the chief marts of the trade of Upper Egypt; 162 miles S. of Cairo. N. lat. 27° 25′. E. long. 31° 38′. Savary. Browne. Sonnini.

SIVVENS, in *Medicine*. See Sibbens.

SIWA, Siwah, *Siouah*, or *See-wah*, in *Geography*, a town of Africa, in the country of Tripoli, on the frontiers of Egypt, ſuppoſed by ſome to be the ancient Mareotis, and by others to be the Siropum of Ptolemy. According to Mr. Browne, this place anſwers to the deſcription given of the Oaſis (ſee Oasis), as being a ſmall fertile ſpot, ſurrounded on all ſides by deſart land. A path, encompaſſed with date-trees, leads to the town, which gives name to the diſtrict. About two miles from this place, after paſſing along ſome ſhady paths between the gardens, Mr. Browne arrived at what were called the ruins, or "birbé;" and was ſurpriſed to find himſelf near a building of undoubted antiquity, and which he has particularly deſcribed. It is ſituated in N. lat. 29° 12′. E. long. 26° 35′. This edifice conſiſted of a ſingle apartment, built of maſſy ſtones, of the ſame kind with thoſe which compoſe the pyramids, and covered originally with ſix large and ſolid blocks, that reach from one wall to the other; 32 feet long in the clear, about 18 high, and 15 wide. A gate, at one extremity, forms the principal entrance, and two doors alſo near that extremity open oppoſite to each other. The other end is quite ruinous, but there is reaſon to believe that the whole building has never been much larger than it now is. On the exterior of the walls there is no ſculpture, nor is there any appearance of another edifice having been attached to it. In the interior are three rows of emblematical figures, apparently deſigned to repreſent a proceſſion; and the ſpace between them is filled with hieroglyphic characters: the ſoffit is alſo adorned in the ſame manner; five of the ſix ſtones remain entire, but the other has fallen within, and thus the connection is broken. The ſculpture is ſufficiently diſtinguiſhable; and even the colours in ſome places remain. The ſoil around ſeems to indicate that other buildings have formerly exiſted near this place. In a rock not far diſtant there are apartments, which have the appearance of places of ſepulture. Although they are without ornament or inſcription, they ſeem to have been hewn with ſome labour. They appear to have been all opened, but no circumſtances point out with certainty the uſes to which they have been applied. Nevertheleſs here are many parts of human ſkulls, and other bones, with fragments of ſkin, and even of hair, attached to them. All of them appear to have undergone the action of fire; but whether they are the remains of bodies repoſited there by a people accuſtomed to burn the dead, or whether they have been burned in this their detached ſtate by the preſent inhabitants, it is now difficult to determine. Yet the ſize of the catacombs would induce one to conclude, that they were deſigned for bodies in an unmutilated ſtate; the proportions being twelve feet in length, ſix in width, and about ſix in height. The number of theſe caverns may amount to thirty or more.

The Oaſis, which contains the town of Siwa, is ſtated by Mr. Browne to be about ſix miles long, and four and a half or five wide. Mr. Horneman, who viſited this country ſince Mr. Browne, ſays, that the principal and fertile territory of Siwah is 50 miles in circumference; but unleſs there be a miſtake in numbers, 50 being inſerted inſtead of 15, which is not improbable, he differs from all others; unleſs indeed we ſuppoſe, that he included the whole diſtrict within the ſurrounding mountains, without conſidering that between theſe and the Oaſis are extenſive plains of barren ſand. A large proportion of the ſpace in which Siwa is ſituated is filled with date-trees, and there are alſo pomegranates, figs and olives, apricots and plantains; and the gardens are remarkably flouriſhing. They cultivate a conſiderable quantity of rice, of a reddiſh hue, and different from that of the Delta. The remainder of the cultivable land furniſhes wheat enough for the conſumption of the inhabitants. Here is abundance of water, both ſalt and freſh; but the ſprings which furniſh the latter are moſtly tepid; and ſuch is the nature of the water, air, and other circumſtances, that ſtrangers are often affected with agues and malignant fevers. It is obſerved by the natives concerning one of the ſprings, which riſes near the building above deſcribed, that it is ſometimes cold and ſometimes warm.

The complexion of the people in this diſtrict is generally darker than that of the Egyptians; and their dialect is alſo different. They are not in the habitual uſe either of coffee or tobacco. The dreſs of the lower claſs is very ſimple, as they are almoſt naked; and the coſtume of the inhabitants, as far as it could be diſcerned, approached nearer to that of the Arabs of the deſart than thoſe of the Egyptians or Moors. Their clothing conſiſts of a ſhirt of white cotton, with large ſleeves, and reaching to the feet, a red Tunis cap, without a turban, and ſhoes of the ſame colour. Some earthen ware made by themſelves, and a few mats, form the chief part of their houſehold furniture; none but thoſe of the richer claſs being furniſhed with copper utenſils. They occaſionally purchaſe a few ſlaves from the Murzouk caravan. Their remaining wants are ſupplied from Cairo or Alexandria, whither they tranſport their dates, both in a dry ſtate, and beaten into a maſs, which when good reſemble in ſome degree a ſweet-meat. They eat no large quantity of animal food, and bread of the kind known to us is uncommon. Flat cakes, without leaven, kneaded and then half baked, form part of their nouriſhment. The remainder conſiſts of thin ſheets of paſte, fried in the oil of the palm-tree, rice, milk, dates, &c. They drink, in large quantities, the liquor extracted from the date-tree, which has often the power of inebriating. Their domeſtic animals are the hairy ſheep and goat of Egypt, the aſs, and a very ſmall number of oxen and camels. The women are veiled, as in Egypt. After the rains, the ground in the neighbourhood of Siwa is covered with ſalt for many weeks. Browne's Travels.

SIWA, in *Mythology*, a goddeſs of the Germans, repreſented in her ſtatue naked, with her hair falling down behind as far as her knees, and holding in one hand a bunch of grapes, and in the other an apple. She is taken for Venus, or for the goddeſs of health. Others take her for a rural divinity, the Pomona of Luſatia.

SIWALON, in *Geography*, a rock in the Eaſt Indian ſea, near the north coaſt of Java. S. lat. 6° 36′. E. long. 110° 49′.

SIXAIN, SIXTH, *Sexagena*, in *War*, an ancient order of battle, in which ſix battalions being ranged in one line, the ſecond and fifth were made to advance, to form the vanguard; the firſt and ſixth to retire, to form the rear-guard; the third and fourth remaining on the ſpot, to form the corps, or body of the battle.

The word is French, ſignifying the ſame thing.

SIX-CLERKS, officers in chancery of great account, next in degree below the twelve maſters; whoſe buſineſs is to enrol commiſſions, pardons, patents, warrants, &c. which paſs the great ſeal, and to tranſact and file all proceedings by bill, anſwer, &c.

They were anciently *clerici*, and forfeited their places, if they married; but when the conſtitution of the court began to alter, a law was made to permit them to marry. (Stat. 14 & 15 Hen. VIII. cap. 8.) They are alſo ſolicitors for parties in ſuits depending in the court of chancery.

Under them are ſix deputies and ſixty clerks, who, with the under clerks, do the buſineſs of the office.

SIX-FOUR, in *Geography*, a town of France, in the department of the Var; 9 miles S.W. of Toulon.

SIXHINDEMEN. See SYXHINDEMEN.

SIX-ISLANDS, in *Geography*, ſmall iſlands in the Eaſt Indian ſea. S. lat. 6° 37′. E. long. 71° 26′.

SIX-MEN FORT, a fort of the iſland of Barbadoes; 1 mile N. of Speight's Town.

SIX-MEN's *Bay*, a bay on the north-weſt coaſt of the iſland of Barbadoes.

SIX-MILE BRIDGE, a poſt-town of the county of Limerick, Ireland; 6 miles S. of that city, on the road to Cork, and 102 miles S.W. from Dublin. There is another town of the ſame name weſt of Limerick, on the road to Ennis, and in the county of Clare, which is $102\frac{3}{4}$ miles W.S.W. from Dublin. The latter town is on the river Gearna or Owgarne, (*i. e.* Owin Gearn, river Gearna,) which falls into the Shannon, where Bunratty caſtle ſtood; and had ſome eccleſiaſtical buildings in former days.

SIX-MILE *Creek*, a ſmall ſtream in the ſtate of New York, that enters the head of Canoge lake at Ithecal. A part of the creek is in the north-eaſt part of Tioga county, where it furniſhes excellent mill-ſeats. Its courſe is ſeventeen miles.

Six-mile *Croſs*, a fair-town of the county of Tyrone, Ireland, where there is a church. It is 7 miles S.E. from Omagh.

Six-mile *Water*, a river of the county of Antrim, Ireland, which riſes in Agnew's hill, near Larne, and running ſouth-weſt, falls into Lough Neegh, below the town of Antrim. The valley of this river, containing ſeveral villages, is a fine ſpecimen of the beauty and cultivation of the county, to which the frequent white-thorn hedges contribute not a little; ſhewing, as the plains about Antrim are approached, the increaſing richneſs of the ſoil, by their ſuperior ſize and vigour. Dubourdieu's Antrim.

SIX-NATIONS, a confederacy of American Indians, ſo called by the Britiſh and Americans, and by the French Iroquois. They are Mohawks, Oneidas, Onondagas, Senecas, Cayugas, and Tuſcaroras. In the American war they took part with Great Britain, and in 1770 they were totally defeated by the troops of Congreſs. Many of them have removed to Canada; and in 1796 they amounted to 4058 perſons. In this year a ſociety of Friends or Quakers raiſed a fund, towards promoting the civilization and comforts of theſe poor people.

SIXT, a town of France, in the department of the Ille and Vilaine; 6 miles N. of Redon.

SIXTH, Sesta, Ital., *Sixte*, Fr., in *Muſic*, the ſecond of the two imperfect concords, called by the Greeks Hexachordon, becauſe its interval is formed of ſix ſounds, or five diatonic degrees. The ſixth is only a natural conſonance by combination; for in the order of concords there is no ſimple and direct ſixth.

To conſider ſixths by their intervals, there are four different ſorts; two conſonant, and two diſſonant. The conſonant are, firſt, the *minor* ſixth, compoſed of three tones, and two major ſemitones; as E C: its ratio is 5 to 8. Secondly, the *major* ſixth, compoſed of four tones, and a ſemitone major; as G E: its ratio is 3 to 5.

The diſſonant ſixths are the extreme flat, and the extreme ſharp ſixths; as B♭ and G♯, called by the French the ſuperfluous ſixth; and C♯ and A♭. Neither of theſe intervals can be uſed in melody, and only the firſt in harmony.

Dr. Pepuſch has given eight examples of the allowable uſe of the ſixth in two parts; and Rouſſeau has given a liſt of ſeven chords, in which ſixths are employed. Theſe are, firſt, the ſimple chord of the ſixth to the third of a key, when that third is the ſuppoſed baſe, inſtead of its fundamental. This kind of chord, which is the common chord to the third below the baſe, may be given likewiſe to the ſecond and the ſharp ſeventh of a key. The ſecond uſe of the ſixth is with the fourth, which is ſtill a perfect concord to the fifth below the baſe. The third uſe of the ſixth is in the chord of the $\begin{smallmatrix}6\\4\\3\end{smallmatrix}$, which is the chord of the ſeventh to the fifth below the baſe, with a ſharp third. The fourth uſe of the ſixth is in the chord or harmony of the $\begin{smallmatrix}6\\5\end{smallmatrix}$, which is the chord of the ſeventh to the minor third below the baſe. This harmony is uſually given to the fourth of a key.

The fifth uſe of the ſixth is in what Rameau calls *le double emploi*, or double uſe of the $\begin{smallmatrix}6\\5\end{smallmatrix}$; when either of theſe intervals may be regarded as the diſcord. If the fifth is made a diſcord by the ſixth, it muſt be reſolved by *deſcending* on a concord; but if, as before a cloſe, the ſixth is regarded as the diſcord, it muſt be reſolved by *aſcending* to another ſixth, while the fifth remains for a fourth to the next baſe. See Double *Emploi*, and Resolution.

The ſixth uſe of the ſixth is that of the major ſixth and falſe fifth, which is the chord of the extreme flat ſeventh to the ſecond of a minor key, in which the falſe fifth is taken, inſtead of the fourth.

Laſtly, the ſeventh uſe of the ſixth is in the chord of the extreme ſharp ſixth, uſed only to the ſixth of a minor key; as D♯ to F♮, when the baſe deſcends to E, the fifth of the key, with a ſharp third. This is an original chord, which cannot be inverted. All theſe chords will be given in notation on the muſic plates, in the rules for accompaniment, or thorough-baſe. The major ſixth is nine ſemitones or half notes above the baſe; the minor ſixth, eight.

The ſixths major and minor, being inverſions of the thirds in compoſition and accompaniment, may, in two parts, move in ſucceſſion upwards and downwards at pleaſure. It has, in a regular deſcent, a ſolemn and melancholy effect, more pleaſing than in a regular aſcent. In compoſition and accompaniment, this concord is accompanied by the $\begin{smallmatrix}8\\3\end{smallmatrix}$, or by its octave and a third, or by two thirds. In thorough-baſe, doubling the ſixth or third, when the movement is not very rapid, enriches the chord and the harmony more than the eighth.

Sixth *Rates*. See Rate.

SIXTUS I., pope, in *Biography*, was by birth a Roman, and ſucceeded Alexander I. about the year 119. Very little is known concerning him; and though there are two decretals aſcribed to him, they are generally regarded as forgeries. He died in the year 128, and has been ranked among the martyrs by the church of Rome, though it is not at all aſcertained that he actually ended his life by martyrdom.

Sixtus II., pope, was a deacon of the Roman church at the time he was elected to the pontificate, in the year 257, or, according to ſome authors, in 260. At the requeſt of Dionyſius, biſhop of Alexandria, he put an end to a diſpute commenced between his predeceſſor, Stephen, and St. Cyprian, concerning baptiſm adminiſtered by heretics. A perſecution was at this time raging againſt the Chriſtians in conſequence of a reſcript of the emperor Valerian, directing that ſearch ſhould be made for all biſhops, prieſts, and deacons, in order to be put to death. Sixtus was one of the firſt victims, being beheaded after he had occupied the papal chair almoſt a year.

Sixtus III., pope, a Roman, was long regarded as one of the principal ornaments of the church of Rome. In 418 he was a favourer and protector of the Pelagians; but when their opinions were condemned by Zoſimus, he was one of the firſt who pronounced an anathema againſt them, and made a public declaration of his orthodoxy. He was raiſed to the pontifical throne in 432, on the death of Celeſtine. It was about this period that the Eaſtern churches were divided concerning the condemnation of Neſtorius; Cyril, with the Egyptian biſhops, maintaining the juſtice of that act; while John of Antioch, and other Oriental biſhops, refuſed to concur in it. By the exertions of Sixtus the parties were reconciled. The Illyrian biſhops made an attempt in the pontificate of Sixtus to free themſelves from the papal juriſdiction, but they were induced by his letters to renounce their purpoſe. The munificence of this pontiff was diſplayed in various repairs and rich decorations of churches in

Rome. He died in 440, after a reign of eight years, and his name has been enrolled among thoſe of the ſaints of the holy Roman ſee.

Sixtus IV., pope, who aſſumed the name of Sixtus, inſtead of Francis della Rovere, was deſcended from a family of the ſame name in Savona, in the ſtate of Genoa. He was born in 1414, and at an early age entered into the Franciſcan order. He ſtudied in the univerſities of Pavia and Bologna, and having taken the degrees of doctor of philoſophy and theology, he gave public lectures in ſeveral of the principal cities of Italy, and acquired great reputation for learning. Having paſſed through ſome honourable offices in his order, he was at length raiſed to the head of it as general; and becoming known to cardinal Beſſarion, through his recommendation, and that of cardinal Gonzaga, he was promoted by pope Paul II., in 1467, to the purple, by the title of St. Peter ad Vincula. On the death of the pope, in 1471, he was raiſed to the pontifical chair; but on his coronation a tumult was excited that had nearly proved fatal to him. Eſcaping from the hands of the mob, he attempted to form a league among the Chriſtian princes againſt the Turks, who had made themſelves maſters of Boſnia, Iſtria, and great part of Dalmatia, and threatened Italy. With this view he ſent ſome of his moſt diſtinguiſhed cardinals as his legates to different courts, with inſtructions to endeavour to compoſe the diſputes exiſting between the ſeveral ſovereigns; but, as uſual in ſuch caſes, with ſmall effect. He procured to be fitted out an allied fleet of gallies, which recovered Smyrna from the Turks, but he did little beſides. He was more ſucceſsful at home, in an attempt to expel a number of petty tyrants who had ſeized upon the cities belonging to the church, and governed them as independent ſovereigns. With the aid of Ferdinand, king of Naples, he effectually cleared the eccleſiaſtical ſtates of theſe uſurpers, and thereby almoſt doubled his revenue. The year 1475 was that of the Jubilee, which was celebrated with great magnificence by Sixtus, and was dignified by an unuſual aſſemblage of crowned heads, though the reſort of pilgrims in general was leſs than on former occaſions.

This pontiff carried the vice of nepotiſm to as great a degree as any of his predeceſſors, and it was one of his firſt objects to make a ſplendid proviſion for his natural children, under the name of nephews, out of the dignities and offices of the church. It is ſaid, that one leading motive for his expelling the independent poſſeſſors of towns in the eccleſiaſtical ſtate was, that he might have territories to form principalities for his nephew; and in purſuance of this plan, he ſent Giulano de Rovere, afterwards Julius II., to take the city of Caſtello from Niccolo Vitelli. Niccolo, having obtained the aſſiſtance of the duke of Milan and the Florentines, made a vigorous reſiſtance, but was at length obliged to capitulate. This produced an alarm in the neighbouring ſtates, and occaſioned a defenſive league between the duke of Milan, the Venetians, and the Florentines. The latter people were under the influence of Lorenzo de Medici, whoſe political conduct could not but be highly diſpleaſing to the pope; and he diſplayed his reſentment by depriving Lorenzo of the office of treaſurer of the holy ſee, which he had conferred upon him in the days of their friendſhip. This, however, was not ſufficient, and he determined upon an attempt entirely to ſubvert the power of the Medici in Florence. In conjunction with his nephew, Girolamo Riario, he formed a moſt deteſtable conſpiracy. By means of the powerful family of the Pazzi, rivals to the Medici in Florence, a revolution was to be effected in the government of that city, commencing with the aſſaſſination of Lorenzo and Giuliano de Medici, when aſſiſting at maſs in one of the churches, and the elevation of the hoſt was to be the ſignal. Fortunately their plans miſcarried, but the pope thundered out an excommunication againſt Lorenzo and the magiſtrates of Florence, and laid the city and its territories under an interdict. Having in vain endeavoured by menace to induce the Florentines to deliver up Lorenzo, he formed a league with the king of Naples, whoſe troops, in conjunction with thoſe of the church, invaded the territory of Florence, and ſpread devaſtation through it. They were, however, encountered by an oppoſite league, and the pope was at length, by the interpoſition of the king of France, and the alarm excited throughout Italy in conſequence of the capture of Otranto by the Turks, obliged to conſent to a peace. Italy did not long remain in peace. In 1482, Sixtus joined with the Venetians in an attempt to diſpoſſeſs the duke of Ferrara of his territories, for which his motive was a hope of veſting the government of that city in one of his own family. The conſequence was an invaſion of the eccleſiaſtical ſtate by the duke of Calabria, ſon of the king of Naples, which however terminated in the duke's total defeat. The ſucceſs of the Venetians rendering them formidable to their neighbours, a league was formed againſt them, which the pope was perſuaded to join, and he iſſued a ſolemn excommunication againſt his allies. The confederates, however, receiving propoſals from the Venetians, concluded a peace without conſulting Sixtus. This affected his holineſs ſo much, that it occaſioned a ſevere fit of the gout, which put an end to his life in 1484, juſt after he had completed his 70th year, and in the 13th of his pontificate. "Sixtus IV." ſays his biographer, "ranks among the moſt unprincipled of the Roman pontiffs with reſpect to political conduct, which ſeems to have been governed by no other motive than the paſſion for aggrandizing his family, and indulging a rapacious diſpoſition. His concurrence in the deteſtable conſpiracy of the Pazzi, and the eagerneſs with which he fermented the wars which diſquieted Italy almoſt through the whole of his reign, ſhew him to have been ſteeled againſt all ſentiments of public juſtice and humanity. He has been taxed with avarice, but the imputation has been refuted by recounting the ſplendid edifices, and the numerous charitable and uſeful eſtabliſhments of which he was the founder. He was, in truth, liberal and magnificent in his expenditure; and having, like many other arbitrary princes of that character, exhauſted his reſources, he ſcrupled no means of repleniſhing them. In no pontificate were the offices and employments about the papal court more ſhameleſsly ſet to ſale, or the exactions in paſſing bulls and other official inſtruments from that court more ſcandalouſly augmented. The moſt favourable light in which he can be viewed, is as a munificent encourager of literature. He may almoſt be regarded as the founder of the Vatican library, for he not only enriched it with books, collected from various parts of the world, but cauſed them to be properly diſpoſed for the convenience of the public, to which he opened the library, placed them under the care of men deeply learned in different languages, with competent ſalaries, and aſſigned funds for the purchaſe of new books. It is, on the other hand, to be mentioned, that he was the firſt who inſtituted inquiſitors of the preſs, without whoſe licence no work was ſuffered to be printed." Sixtus was author of ſome theological pieces: ſeveral of his letters are extant, and he publiſhed ſome decrees, one of which had for its object to put an end to the diſputes then ſubſiſting relative to the conception of the Virgin Mary.

Sixtus V., pope, was born in 1521, in the Marche of Ancona, at La Grotte, a village in the territory of Montalto.

talto. His father, whoſe name was Peretti, was a vine-dreſſer, who not being able to maintain his ſon, placed him, when he was only nine years old, in the ſervice of a farmer, by whom he was, at firſt, chiefly employed in attending to his ſwine. While he was occupied in this low office, a Franciſcan friar paſſing that way, took the lad for his guide on a journey to Aſcoli. Pleaſed with the boy's vivacity, he cauſed him to accompany him to his convent, and introduced him to his father guardian, who admitted him into the convent in the quality of a lay brother. He ſoon manifeſted a great inclination for learning, and was taught the elements of the Latin language. He was ſoon admitted into the order, went through the uſual courſes of philoſophy and theology, was ordained prieſt in 1545, and ſhortly afterwards, being made a doctor in theology, he was appointed to a profeſſorſhip at Sienna, under the name of Montalto. He acquired a high reputation as a preacher in ſeveral Italian cities, and was in a very ſhort time nominated commiſſary-general at Bologna, and inquiſitor at Venice. In the exerciſe of the latter office he quarrelled with the ſenate, always jealous of eccleſiaſtical authority, and thought proper to make his eſcape from Venice by night. Going to Rome, he became one of the council of the congregation, and afterwards procurator-general of his order. He accompanied cardinal Buoncompagno to Spain, in quality of theologian to the ſenate, and counſellor of the holy-office. Thus elevated, he ſuddenly changed his demeanour, which had been harſh and petulant, and put on an appearance of extraordinary gentleneſs and humility. Cardinal Alexandrini, formerly his pupil, being raiſed to the papal dignity by the name of Pius V., ſent him the brief of general of his order, and ſoon after honoured him with the purple, when he took the name of cardinal Montalto. The ſucceſſor of Pius was Gregory XIII., formerly cardinal Buoncompagno.

Montalto, without influence or connections to puſh him forward at the next vacancy, determined to appear entirely void of wiſhes and expectation of farther elevation, in order that he might not become an object of jealouſy to any party. He accordingly withdrew from all public affairs, ſhut himſelf up like one entirely devoted to ſtudy and religious retirement, and ever complained of the infirmities of age hanging heavily upon him. Gregory died in 1585, and the cardinals ſplit into factions. Montalto appeared, but in the character of one bending under the weight of years, and as if ready to expire. In the courſe of the conteſts, which were long and ſevere, he was informed that the choice would probably fall on him; to which he replied by averring his own unfitneſs for the office; that his life would ſcarcely outlive the conclave; and that if he were elected, he ſhould only be pope in name, while all the authorities muſt devolve upon others. This ſort of argument, which he threw out as a bait to his ambitious brethren, was readily ſeized upon by them all, as well with the hope of a ſhort pontificate, as with the expectation that they ſhould all ſtrengthen themſelves againſt a new election. Montalto was choſen on the 24th of April, 1585. Scarcely, however, had the tiara been placed on his head, when he threw away his crutches, which had enabled him to aſſume his former character, walked perfectly erect, and chanted Te Deum with a voice ſo ſtrong, that the roof of the chapel in which the ceremony was performed re-echoed the ſound. He alſo gave his benediction to the people with ſuch an air of vigour, that they could ſcarcely believe him to be the decrepid cardinal Montalto. It was now that he aſſumed the name of Sixtus V., and he ſoon ſhewed them that his mind was as vigorous as his body. The territory of the church was at this time overrun with banditti, who plundered and even murdered the people with impunity; and in the metropolitan city itſelf, a relaxed police had encouraged all kinds of diſorders. The firſt object of Sixtus was to exterminate theſe evils, and no ſovereign ever employed the corrective powers with which he was inveſted with more vigour and effect. It had been uſual, for the ſake of acquiring popularity, on the election of a new pope, to ſet the impriſoned criminals at liberty; but the firſt act of Sixtus was to order four perſons to be hanged, on whom were found, a few days before, prohibited weapons. This ſyſtem of rigour he purſued with the moſt inexorable ſeverity, never, in a ſingle inſtance, pardoning a criminal. There is no doubt that ſignal ſeverity was neceſſary to ſtop the public diſorders, and in that view of the ſubject, Sixtus was certainly a benefactor to the ſtate; but unfortunately for his character as a juſt magiſtrate, in whom compaſſion ſhould be found tempering the rigour of the law, inſtances are recorded on the page of hiſtory which go to prove that he took a real pleaſure in acts of puniſhment, and that his ſoul was inſenſible to all the emotions of tenderneſs and pity; which, ſays a good writer and diligent obſerver of human nature, “ is not an unuſual effect of a monaſtic education.”

A Spaniſh gentleman having been ſtruck by a Swiſs guard with his halberd in a church, retaliated by a blow which proved fatal to the ſoldier. Sixtus, having examined into the affair, gave an order to the governor of Rome to have the offender executed before he ſhould ſit down to table. The Spaniſh ambaſſador, with four cardinals, waited upon his holineſs, not to plead for the criminal's life, but to entreat upon their knees, that, as he was a gentleman by birth, the puniſhment might be commuted to that of decapitation: this ſmall favour he abſolutely refuſed, and ſaid in a tone of anger, bordering on frantic rage, “ he ſhall be hanged; but to alleviate the diſgrace incurred by his family, I will do him the honour to aſſiſt at his execution.” He accordingly ordered the gallows to be erected before his own houſe, and was witneſs to the deed of horror. When the ſentence was executed, he turned with the utmoſt coolneſs to his domeſtics, and ſaid, “ Bring me my dinner; this act of juſtice has given me an additional appetite.” He cauſed the heads of all thoſe who had ſuffered the penalty of death for crimes committed againſt the ſtate, to be placed on the city gates, and on each ſide of the bridge of St. Angelo, and ſometimes went on purpoſe to view them; and a requeſt being made by the conſervators of the health of the city for their removal, when they, by their numbers and decay, became offenſive, he replied, “ You are too delicate; the heads of thoſe that rob the public are ſtill more offenſive.”

Another anecdote is told of him, to ſhew that he was not more rigorous to his own ſubjects, than ſtrenuous in maintaining the rights and authority of the holy ſee, with reſpect to foreign powers. When the ambaſſador of the king of Spain preſented him with a beautiful genet and a purſe of ducats, as a homage due for the kingdom of Naples, and complimented him in his maſter's name, Sixtus, in a tone of raillery, ſaid, that the compliment was very fine, but that it would require a deal of eloquence to perſuade him to take a horſe in exchange for the revenues of a kingdom. At the time of his acceſſion, France was in confuſion on account of the machinations of the Catholic league to exclude from the crown Henry, king of Navarre, its preſumptive heir. Though Sixtus did not approve the attempts of the Guiſes, at the head of the league, to obtain a ſuperiority over the king, Henry III.; yet he thought it became him, as head of the Catholic religion, to promote the excluſion of a Proteſtant heir, and he accordingly launched an excommunication againſt the king of Navarre, depriving him of the right of ſucceſſion. That prince procured an appeal from this ſentence to be fixed on the very gates of the Vatican, which act, Sixtus had the magnanimity to be pleaſed with, on account of the heroiſm which it diſplayed. When Henry III. had cauſed the duke of Guiſe to be aſſaſſinated, and the cardinal of Guiſe to be put to death, and the cardinal of Bourbon and the archbiſhop of Lyons to be impriſoned, the pope, highly incenſed at the violation of the eccleſiaſtical immunities in the perſons of the three laſt mentioned perſons, iſſued a monitory, requiring the king to ſet at liberty the cardinal and archbiſhop within ten days, on pain of excommunication; and he afterwards approved, in an open manner, the aſſaſſination of Henry by the Dominican Clement. He refuſed, however, to renew the excommunication of Henry IV., ſaying, that he would pray for his converſion, and that no prince was more deſerving a crown. He had alſo a high veneration for the character of queen Elizabeth of England, on account of the prudence and vigour of her government, though he was under the neceſſity of treating her as an enemy on account of her enmity to the Catholic religion. It is ſaid, and the fact is ſurely quite in character, that he envied her the good fortune in having had the pleaſure of taking off a crowned head, by the execution of Mary, queen of Scots. After the defeat of the Spaniſh armada, he entertained the deſign of wreſting the kingdom of Naples from Philip, but was prevented by death from making the daring attempt.

It was the ruling paſſion of this pontiff, who, as we have ſeen, was only a peaſant's ſon, to perpetuate his memory, by which he was led to many vain and oſtentatious, and to ſome great and uſeful enterpriſes. He had already, while cardinal, engaged the celebrated architect Fontana, in erecting a ſplendid chapel in the church of St. Maria Maggiore, which he had been obliged to diſcontinue, from the withdrawing of his allowance by Gregory XIII.; and now having the means, as well as the good will, he employed the ſame artiſt in the arduous taſk of ſetting upright the fallen obeliſk of Egyptian granite, which had once decorated the Circus of Nero. This was effected by great ſkill and labour, and the obeliſk was dedicated by Sixtus to the Holy Croſs. He afterwards cauſed three other obeliſks to be dug out of the ruins among which they lay, and placed before different churches. If mere vanity and oſtentation led him to erect uſeleſs buildings at his native place; it was univerſally allowed, that uſe and ornament were united in moſt of the works which he executed at Rome. For the ſupply of water to that metropolis, he directed the collection of a number of ſprings to one reſervoir, at the diſtance of thirteen miles, whence it was conveyed by an aqueduct to the Quirinal mount. He undertook to rebuild the Vatican library upon an enlarged and more magnificent plan, by his favourite architect Fontana, and erected very near it a very fine printing-office, deſtined to give ſplendid as well as correct editions of the fathers, and other works relative to religion. There was not a part of Rome to which he had not given decorations, and perhaps no pope left ſo many monuments of grandeur after a long reign as Sixtus V., after occupying the papal ſee little more than five years. On theſe objects he muſt have expended immenſe ſums, yet at his death he left five millions of crowns in the caſtle of St. Angelo, with an injunction to his ſucceſſor, that they ſhould be expended only for the ſervice of the church, againſt Turks and heretics, or to relieve the people in times of famine and peſtilence. For the ſupply of the great expenditure of his reign, and the accumulation of the ſums left behind him, he muſt have had recourſe to a ſyſtem of heavy taxation, although he managed his finances with great economy. He was not free from the papal vice of nepotiſm. Though never aſhamed of the meanneſs of his origin, which could not be concealed, he was determined to leave his family great. He ſent for a ſiſter, the widow of a poor countryman, and inſtantly gave her the rank of a princeſs, with a ſuitable maintenance; and he raiſed one of her grandſons to the cardinalate, with a very large revenue. He was equally liberal to his other relations. He fixed the number of cardinals to ſeventy, a number which has been adhered to by his ſucceſſors; and he decreed, that four at leaſt of the number ſhould be doctors of divinity, choſen from the religious orders. He is ſaid to have been a decided enemy to the Jeſuits, and was indignant that they ſhould aſſume a name that implied, that their founder was the meek and benevolent Jeſus; hence he propoſed that they ſhould change the name of their order to that of Ignatians. This celebrated pontiff died in Auguſt 1590, having reigned five years and four months. The news of his death was received with every demonſtration of joy at Rome, where his government had been oppreſſive and tyrannical; but the vigour of his adminiſtration, and the mighty works which he effected, have thrown a ſplendour about his name, and gave him rank among the diſtinguiſhed characters of the age. In the year 1590, a new Latin verſion of the Bible was made and printed by his order, of which a corrected edition was given in 1592, by Clement VIII.

SIZADA, in *Geography*, a town of Hindooſtan, in Allahabad; 20 miles S.E. of Corah.

SIZANDRO, a river of Portugal, which runs into the Atlantic, N. lat. 39° 2′. W. long. 9° 19′.

SIZE, the name of an inſtrument uſed to find the bigneſs of fine round pearls.

It conſiſts of thin pieces, or leaves, about two inches long, and half an inch broad; faſtened together at one end by a rivet. In each of theſe are ſeveral round holes drilled, of different diameters. Thoſe in the firſt leaf ſerve for meaſuring pearls from half a grain to ſeven grains. Thoſe of the ſecond, for pearls from eight grains, or two carats, to five carats, &c.: and thoſe of the third, for pearls from ſix and a half to eight and a half.

Size is alſo uſed for a kind of weak glue. (See Glue.) The ſhreds and parings of leather, parchment, or vellum, by being boiled in water and ſtrained, make ſize. Common ſize is made of leather boiled in water till it becomes of a viſcid conſiſtence. If it is wanted in painting for nicer purpoſes, it ſhould be prepared by taking any quantity of the ſhreds or cuttings of glovers' leather, and putting to each pound a gallon of water; let theſe be boiled for ſix or eight hours, ſupplying water, ſo that it may not diminiſh to leſs than two quarts. Then ſtrain the hot fluid through a flannel, and afterwards evaporate it till it is of the conſiſtence of a jelly when cold. The ſize uſed in burniſh gilding, and made of cuttings of parchment, is prepared much after the ſame manner. This ſubſtance is uſeful in many trades. Mr. Boyle mentions, among other uſes, that fine red ſtands, and hanging-ſhelves, are coloured with ground vermilion tempered with ſize, and when dry, are laid over with common varniſh.

Size, *Gold.* See Gold-*ſize.*

SIZE, *Iſinglaſs.* See ICHTHYOCOLLA.

SIZE, *Painting.* See DISTEMPER.

SIZE *for Silvering.* See SILVERING.

SIZE *of Cottage Grounds*, in *Agriculture.* See COTTAGE.

SIZE *of Farms*, the particular dimenſions or extents of them. The advantages of the different ſizes of farms, ſo far as they relate to the occupiers and the community at large, have not yet been by any means aſcertained. See FARM.

SIZE *of Fields or Incloſures.* See FENCE, FIELD, and INCLOSING *of Land.*

SIZEBOLI, in *Geography*, a town of European Turkey, in Romania, on a point of land which projects into the Black ſea, with a good road, in which men of war may moor. It is the ſee of a Greek archbiſhop; 14 miles E. of Burgos. N. lat. 42° 30′. E. long. 27° 44′.

SIZEL, in *Coining*, is uſed where pieces of money are cut out from flat bars of ſilver, after having been drawn through a mill into the reſpective ſizes or dimenſions of the money to be made; the reſidue is called ſizel, and melted down again.

SIZING, in *Mineralogy*, a term uſed by the Corniſh miners for a peculiar method of ſeparating the purer from the impurer parts of an ore, by means of ſieves. When the ore has been powdered, they put it into a wire-ſieve with fine holes, and in this they ſift it, till the fine part goes through: this is properly what is called ſizing. They ſend the larger or coarſer part to be powdered again, and putting the reſt into a ſieve with a cloſe bottom, they let in a ſtream of water from the cock, and by means of continued ſhaking it about, they cauſe the lighter and fouler parts to be waſhed over the rims of the ſieve, and the remaining powder is the black tin.

SIZRAN, in *Geography*, a town of Ruſſia, in the government of Simbirſk, on the Volga; 27 miles S. of Simbirſk. N. lat. 53° 10′. E. long. 48° 14′.

SIZUN, a town of France, in the department of Finiſterre; 6 miles S.E. of Landerneau.

SIZZELA, a town of Iſtria; 9 miles S.S.W. of Cape d'Iſtria.

SIZZING, in *Rural Economy*, a term provincially applied to yeaſt or barm.

SKABOUGAN, in *Geography*, a river of America, which runs into lake Michigan, N. lat. 44° 5′. W. long. 86° 46′.

SKAGAFIORD, a bay on the N. coaſt of Iceland. N. lat. 65° 50′. E. long. 15° 21′. This Fiord receives the waters of two rivers, one of which is large, and is called Kolbeinsdalſaa. On the weſtern ſide of the Skagafiord is ſituated a place of trade, called Hoſſos, with a bad harbour, ſo that only one merchant has ſettled there. At the head of the Skagafiord, not far from Hoſſos, is Hoolum, which, until the cloſe of the laſt century, was the ſeat of one of the biſhops of Iceland. A public ſchool was alſo eſtabliſhed there; but now (1810) the place conſiſts only of a few cottages; and in its preſent ſtate contains nothing particularly worthy of notice.

SKAGAFIORD *Syſſel*, a diſtrict of Iceland, containing 412 farms, 492 families, and a population of 3141 perſons.

SKAGASTRAND, a conſiderable place of trade on the northern coaſt of Iceland; ſituated on the weſtern ſide of the large promontory which bounds the Skagafiord. The harbour is bad; and towards the end of September is particularly unſafe, on account of its being expoſed to the north wind and floating ice. This place formerly furniſhed a cargo for one veſſel every year; but ſince the commencement of the war, the arrival even of one ſhip has not been regular.

SKAGEN, a promontory of Iceland, projecting from the N. coaſt, about 20 miles in length from N. to S. and from 5 to 15 in breadth; the N. point being in N. lat. 66°. E. long. 45° 51′.

SKAGEN. See SCAGEN.

SKAGER, a town of Sweden, in Weſt Gothland; 85 miles E.N.E. of Uddevalla.—Alſo, a lake of Sweden, in Warmeland; 5 miles E. from the Wenner lake.

SKALDA and SKALDS. See EDDA and SCALDS.

SKALE, in *Geography*, a ſmall iſland on the W. coaſt of Scotland, in Loch Fine. N. lat. 55° 54′. W. long. 5° 23′.

SKALEN, a town of Pruſſia, in the palatinate of Culm; 13 miles N. of Straſburg.

SKALEVAD, a town of Sweden, in the province of Angermanland; 50 miles N.N.E. of Hernoſand.

SKALGRUND, a ſmall iſland on the E. ſide of the gulf of Bothnia. N. lat. 55° 54′. W. long. 5° 23′.

SKALHOLT, a town of Iceland, the ſee of a biſhop, ſuffragan of Drontheim. N. lat. 64°. W. long. 16°. The ſituation of Skalholt, about 24 miles from *Thingvalla* (which ſee), is beautiful. Towards the ſouth there is a view of a noble river, formed by the junction of that diſcharged from Apa Vatn and the Huitea, bounded by a finely-ſhaped hill in the diſtance; another equally pictureſque hill riſing on the eaſtern bank of the latter, and facing Skalholt. Flat meadow land, gently ſwelling ground, and diſtant mountains towards the eaſt, among which are Eyafialla Jokul, and Hekla, form altogether a magnificent amphitheatre, and compoſe a landſcape which, even without wood, is highly gratifying to the eye. The firſt biſhop of Skalholt was Iſleif, who died in 1080; he was the earlieſt of the Icelandic hiſtorians, and a man of great general learning; but his works are now unfortunately loſt. Paul, another biſhop of Skalholt, as well as Sturleſon, were diſtinguiſhed by their attainments in mathematics and mechanical ſcience. During a period of ſeven centuries, Iceland was divided into two biſhoprics, that of Skalholt comprehending the ſouthern, and that of Hoolum the northern diſtricts of the iſland. The ſees becoming vacant at the ſame time, they were united, in 1797, by the order of the Daniſh government; and the title of biſhop of Iceland was conferred upon the learned and reſpectable Gein Vidalin, the preſent poſſeſſor of this dignity. The duties of his office are important and extenſive. The place of his ſtated reſidence is Reikiavik. His revenue, ſince the union of the ſees, is about 1800 dollars *per annum*, derived chiefly from the public treaſury of the iſland. The appointment of the biſhop is veſted in the crown. The church of Skalholt is a neat ſmall building of wood, erected on the ſcite of the former one, which was taken down about the year 1804. The church, the biſhop's houſe, and a few cottages, conſtitute the ſuppoſed capital of Iceland. The eaſieſt route from the ſouthern to the northern parts of Iceland is by the way of Skalholt. To Skagaſtrand, the neareſt road is by Thingvalla and Kalmanſtunga, which laſt place is ſituated to the N.E. of Reikholt. See Mackenzie's Travels in Iceland in 1810. See ICELAND.

SKALL, a town of Bohemia, in the circle of Boleſlaw; 4 miles N.N.W. of Turnau.

SKALLERUD, a town of Sweden, in the province of Weſt Gothland; 30 miles N.N.E. of Uddevalla.

SKALOE, a ſmall iſland of Denmark, near the N. coaſt of Laaland. N. lat. 55°. E. long. 11° 23′.

SKANANDO Creek, a ſmall water of Oneida creek, which riſes in Auguſta, Oneida county, runs northerly through the ſaid town and Vernon, and enters Oneida creek near the S.W. corner of Vernon. It furniſhes good mill-ſeats in Auguſta and Vernon. Its courſe is about four miles.

SKANDA, in *Hindoo Mythology*, is a name of Kartikya, commander of the celeſtial armies. He is a reputed ſon of Siva, and his hiſtory and exploits fill many volumes of Eaſtern poetry, tranſlated into a variety of languages from the Sanſcrit. He is alſo called Divimatri, having the ſame meaning in Sanſcrit, as Dimeter or Bimater among weſtern mythologiſts. Shanmuka, or ſix-faced, Seſhtimatriya, meaning with ſix mothers, are others of his names; the origin of which will be found under thoſe articles, and Kartikya. (See alſo Siva.) Sir W. Jones informs us that the Perſian poets, in borrowing their romantic hiſtories from thoſe of India, have ridiculouſly confounded the Skanda of the latter with Skander or Iſkander; their name of Alexander the Macedonian, as well as of a hero in their earlier romances.

SKANDERBORG, in *Geography*, a town of Denmark, in North Jutland, where the kings of Denmark have a royal palace: the chief trade of the inhabitants conſiſts in the produce of the country, and agriculture; 10 miles S.S.W. of Aarhuus. N. lat. 56° 55′. E. long. 9° 54′.

SKANEATETES, a lake of New York; 25 miles S.S.E. of lake Ontario.

SKANGERO, a ſmall Grecian iſland below that of Pelagniſi, and near the iſle of Dromi, in which are two rocks, called the "Brothers."

SKANKHEADHAW Lake, a lake of North America. N. lat. 49° 45′. W. long. 90° 45′.

SKANO, a town of Sweden, in Schonen; 20 miles S.S.W. of Lund. N. lat. 55° 24′. E. long. 12° 34′.

SKANTZE, a town of Sweden, in Weſtmanland; 9 miles N. of Stroemſholm.

SKAPTAA-JOKUL, lofty mountains ſituated in the interior of Iceland, and known to the natives themſelves only by the remote view of their ſummits, clad in perpetual ſnows. Theſe were the ſcene of a moſt dreadful volcanic eruption in the year 1783. This is repreſented as the moſt tremendous, perhaps, in its nature and extent, by which Iceland, or any other part of the globe, has been afflicted. The ſudden extinction of a ſubmarine volcano near Cape Reikianes, which, during ſome months, had continued to burn with extreme violence, was ſucceeded by frequent and dreadful earthquakes, and by the burſting out of the volcanic fire, in a tract of country nearly 200 miles diſtant. From this deſolate and unfrequented region vaſt torrents of lava iſſued forth, overwhelming all before them, and filling up the beds of great rivers in their progreſs towards the ſea. For more than a year, a denſe cloud of ſmoke and volcanic aſhes covered the whole of Iceland, obſcuring almoſt entirely the light of the ſun, and extending its effects even to the northern parts of continental Europe: the cattle, ſheep, and horſes of the country were deſtroyed; a famine, with its attendant diſeaſes, broke out among the inhabitants; and the ſmall-pox invaded the iſland at the ſame time with its former virulence and fatal effects. From theſe combined cauſes, more than 11,000 people periſhed during the period of a few years; an extent of calamity which can only be underſtood, by conſidering that this number forms nearly a fourth part of the whole preſent population of the country. The deſtruction of the fiſhery upon the ſouthern coaſts of the iſland, by the volcanic eruptions juſt deſcribed, was another more permanent ſource of diſtreſs, which, even at the preſent time (1810) is not entirely removed. Mackenzie's Travels in Iceland.

SKAPTAFELL, East, a diſtrict of Iceland, on the northern coaſt, containing 53 farms, 126 families, and a population of 911 perſons.

Skaptafell, *Weſt*, a diſtrict of Iceland, on the ſame coaſt, containing 133 farms, 248 families, and 1539 inhabitants.

SKARA, a town of Sweden, in Weſt Gothland, the moſt ancient town of the country, and formerly the capital of the kingdom of Gothland, and the reſidence of many of its kings. It had alſo ſeveral churches and convents, the ruins of which are ſtill viſible. The town was totally deſtroyed by fire in 1719; and the number of its inhabitants does not at preſent exceed 400. Its gymnaſium or ſeminary was eſtabliſhed in 1640, and its cathedral is one of the largeſt edifices of the kind in the whole kingdom. In 1611 the royal palace, built near the town in 1545, together with the whole town, was reduced to aſhes by the Danes. At a diſtance from it ſtands Brunſbo, an epiſcopal ſee; 50 miles E. of Uddevalla. N. lat. 58° 24′. E. long. 13° 30′.

SKARDSA, Biorno *á*, in *Biography*, a learned Icelander, was born at Ingelveſtad in 1574. Having loſt his father at eight years of age, he was placed by a relation under the care of Segurd Jonſen, who being well verſed in the ancient hiſtory of the country, inſpired Biorno with a ſtrong taſte for that kind of ſtudy. On the death of his maſter, in 1602, Biorno married, and having already been elected a magiſtrate, he applied himſelf with great diligence to hiſtory and juriſprudence. In old age he was borne down with heavy and very ſevere afflictions, became blind, and died a martyr to the ſtone in 1655. He collected a variety of documents and curious facts relating to the hiſtory of Iceland, and was, on account of his great knowledge in this department of learning, held in high eſtimation by his countrymen. His chief publication was "The Annals of Biörn à Skardſa, ſive Annales, &c. cum Interpretatione Latina, variantibus Lectionibus, Notis et Indice." He left behind him a great number of manuſcripts, both juridical and hiſtorical, a catalogue of which may be ſeen in the Eccleſiaſtical Hiſtory of Iceland by Johannæus; in Einarus' Literary Hiſtory; and in the preface to the ſecond volume of his Annals. Among his MSS. is one reſpecting Iceland, of which Torfæus made great uſe in his "Grönlandia Antiqua." Gen. Biog.

SKARDUPONEN, in *Geography*, a town of Pruſſian Lithuania; 1 mile N.W. of Stalluponen.

SKARO, a town of Norway; 32 miles N. of Stavanger.

SKARROE, a ſmall iſland of Denmark, near the S. coaſt of Fyen; 6 miles S. of Svenborg. N. lat. 55° 1′. E. long. 10° 29′.

SKARSTA, a town of Sweden, in Weſt Gothland; 40 miles E. of Uddevalla.

SKATE, in *Ichthyology*, the Engliſh name of a ſpecies of ray-fiſh, called by the generality of authors *raia undulata*, and *raia lævis*, and by ſome *rubus*.

It is diſtinguiſhed by Artedi by the name of the variegated ray-fiſh, with the middle of the back ſmooth, and with only one row of ſpines in the tail.

This ſpecies, which is the Raia *Batis* of Linnæus, (ſee Raia,) is the thinneſt, in proportion to its bulk, of any of the genus, and alſo the largeſt, ſome weighing near two hundred pounds. The noſe, though not long, is ſharp-pointed; above the eyes is a ſet of ſhort ſpines; the whole upper part of a pale-brown, and in ſome ſpecies ſtreaked with black; the lower part white, marked with many ſmall black ſpots; the jaws covered with ſmall granulated but ſharp-pointed teeth; the tail is of a moderate length; near the end are two fins; along the top of it is one row of ſpines, and on the edges are irregularly diſperſed a few others. In the males of this ſpecies the fins are full of ſpines. Skates generate in March and April, at which time they ſwim near the ſurface of the water, ſeveral males purſuing one female. The females begin to caſt their purſes, as the fiſhermen call the bags in which the young are included, in May, and continue to do it till September. In October they are very poor and thin, but begin to improve in November, and grow gradually better till May, when they are in the higheſt perfection. The males go ſooner out of ſeaſon than the females. Pennant.

SKAW, in *Geography*. See SKAGEN.

SKAWIN, a town of Poland; 10 miles S. of Cracow.

SKEATTA, or PENNY, in the *Hiſtory of Coinage*, one of the Heptarchic coins; the other being the *ſtyca*, which ſee. Dr. Combe, by cauſing two plates of the ſkeattas, or early pennies, to be engraved, brought them into notice. At firſt they had only rude figures of ſerpents, &c. but latterly they have legends. Theſe ſkeattas were ſtruck in Kent, and the other Heptarchic ſtates, from the ſixth to the eighth century, or from about the year 500 till 700. In 598 Kent was converted to Chriſtianity, and was followed in half a century by the other kingdoms. Moſt of the ſkeattas, as appears from their ſymbols, were ſtruck in the Pagan times. See *Modern* MEDALS and COINS.

SKEDE, in *Geography*, a town of Sweden, in Smaland; 42 miles S.E. of Jonkioping.

SKEEL, in *Agriculture*, provincially a large milking pail, having two handles, formed by two oppoſite ſtaves, which riſe above the reſt. It alſo ſignifies a broad flat creaming or milk-diſh, whether of lead or ſtone.

SKEEN, in *Geography*, a town of Norway, in the province of Chriſtiania; 38 miles S.W. of Chriſtiania.

SKEETS, in the *Sea Language*, narrow oblong ladles, or ſcoops, for wetting the ſails, decks, or ſides of a ſhip.

SKEG, in *Ship-Building*, the after-part of the keel, or that part whereon the ſtern-poſt is fixed.

SKEG-*Shores*, one or two pieces of four-inch plank, put up endways under the ſkeg of the ſhip, to ſteady the after-part a little, when in the act of launching. They are confined to the bottom of the ſlip by a hinge. The upper part is rounded, and they ſhould be ſo carefully fixed as to fall readily when the ſhip ſtarts. Skeg-ſhores are better avoided, as they have been the means of preventing ſhips from launching.

SKEGS, in *Agriculture*, a ſort of oat, ſometimes cultivated as a crop in Nottinghamſhire: the *avena ſtipiformis* of Linnæus. It is panicled, the calyces two-flowered, awns twice as long as the ſeed, culm branchy, and ſtipeform. They are a crop moſtly cultivated, according to the agricultural report of the above diſtrict, on the worſt land, ſometimes on a lea, ſometimes after turnips, often taken as a laſt crop. On bad land they may produce about four quarters *per* acre, which are generally about two-thirds of the price of oats. But they anſwer to ſow on good land, producing fourteen and fifteen quarters *per* acre. The kernel is reckoned remarkably ſweet and good food for horſes. They are ſometimes threſhed, ſometimes cut and uſed in the ſtraw. And they are chiefly grown about Carberton, and will grow where nothing elſe will. In regard to the quantity of ſeed *per* acre, eight ſtrikes are ſaid to be ſown, and yield a crop double that of other oats, in quantity; but not more than equal in weight. They will grow in the pooreſt land, and are reckoned very ſweet food. They are ſeldom brought to market; but eſteemed by farmers for their own uſe, and are often given in the ſtraw by them.

It is ſtated by Mr. Neville in the ſame Report, in a letter to ſir R. Sutton, that ſkegs are remarkably good for horſes, in the ſtraw, or threſhed, and in the ſtraw remarkably ſo for cows. Straw beaſts are alſo very fond of the ſtraw. He can get taking up weak land from the ſwarth, from four to ſix quarters an acre. On the ſame land he ſhould not have been able to get, perhaps, above three ſacks of black, red Frieſland, or what is called ſhort ſmall, or any other kind of corn. If land is in the ſtate in which all our bad land will be, more or leſs, after the ſeeds are quite run out, and as is frequently the caſe, when you cannot conveniently put it again into tillage ſo ſoon as you could wiſh, from either the too great quantity you may have to improve, or other circumſtances; if in this ſtate it were to be taken up with turnips, the moſt eligible way, it would be often impoſſible to provide manure *upon the farm* for any quantity of land ſufficient for the purpoſe; which makes ſkegs a very deſirable crop, and which, for that reaſon alone, he finds a great acquiſition, and feels a pleaſure in having been the firſt to introduce them into this country.

How far this crop may be capable of being grown in other diſtricts as the food of live-ſtock, in the green ſtate, muſt depend upon the trial.

SKEILAY ISLE, in *Geography*, a ſmall iſland of the Hebrides, is ſituated near the weſtern entrance of the ſound of Harris. It is comprehended in the pariſh of Harris and ſhire of Inverneſs.

SKELBOO, a town of Norway, on the Glanmen; 12 miles N.E. of Frederickſtadt.

SKELDNESS, a cape of Scotland, on the S.W. coaſt of the iſland of Shetland. N. lat. 60° 12′. W. long. 1° 48′.

SKELEFTEA, a town of Sweden, in Weſt Bothnia, on a river of the ſame name; 40 miles S. of Pitea.

SKELEFTEA, a river of Swediſh Lapland, which riſes on the borders of Norway, and runs into the gulf of Bothnia, S.E. of Pitea.

SKELETON, in *Anatomy*, from σκελλω, *to dry*, is the aſſemblage and combination of all the bones in the body, excepting the os hyoides: it conſtitutes the baſis or groundwork of the animal frame, being the point of ſupport and union for all the other organs. Its component parts form a ſeries of levers, of which the muſcles are the moving powers: thus the ſkeleton comprehends one diviſion of the moving organs. Its conſtituent pieces in ſome caſes form cavities, as thoſe of the head, cheſt, and pelvis, which contain the important internal organs, and protect them from external force.

The connections of the different pieces of the ſkeleton are called *joints*, and differ very conſiderably from each other; ſome of them admitting no motion, ſome an inconſiderable motion; and others allowing them to move freely, either in certain directions, or in every way. The word *ſkeleton*, denoting the bony fabric in its united ſtate, of courſe includes the joints or media of union; and in this reſpect we diſtinguiſh two kinds of ſkeletons. A *natural* ſkeleton is that in which the bones are all joined by their natural connections; that is, the articular ends are covered by their cartilaginous ſtrata, tied together by ligaments, and enveloped by ſynovial membranes: in this ſenſe the ſkeleton includes, beſides the bony ſyſtem, the acceſſory ſtructures of cartilage, ligament, and ſynovial membranes. When all the ſoft parts have been allowed to putrefy and rot, and the ſeparated bones, after being cleaned and dried, have been joined again by wires, &c. ſo as to be reunited artificially in their former order, an *artificial* ſkeleton is formed. In the ſpine and the ribs, the places of the cartilages, which are loſt in cleaning the bones, are ſupplied by portions of leather, cork, or other materials.

The latter, exhibiting merely the aſſemblage of the dried bones, is applicable to the ſtudy of oſteology only in the mechanical points of figure, ſize, &c.; and although extremely uſeful to the anatomiſt and ſurgeon, by repreſenting the parts in their natural connection and relations, is leſs convenient than the ſeparate bones for the ſtudy of many points, particularly the articular ends of the bones.

For the formation of artificial ſkeletons, the bones are deprived of their ſoft parts, either by boiling, or by maceration in water. The boiling muſt be continued until the tendons, ligaments, perioſteum, &c. are ſo looſened as to admit of being eaſily detached. The bony texture acquires in this method a dirty and greaſy appearance, which cannot be entirely got rid of by any after-proceſs. For the purpoſe of maceration, the bones, with the fleſh, &c. roughly cut off, muſt be left in the ſame water for ſome months; the ſoft parts will then fall off, and leave the bones of a much better colour, and freer from greaſe than when they have been boiled. Expoſure to the air, and frequently wetting them, will make them beautifully white after they have been well macerated. Their colour may be often much improved by expoſure to chlorine (oxymuriatic gas). The bones which poſſeſs large medullary cavities ſhould be bored at the articular ends, to get out the fatty ſubſtance.

Emaciated and particularly anaſarcous ſubjects are the beſt for making ſkeletons; becauſe there is no fat in the bones, and they conſequently continue dry and clean, when they have been originally well prepared. Perſons dying in good health, or from ſudden attacks, have ſo much adipous matter in the interior of their bones, that they continue greaſy, particularly at the articular ends, whatever pains may be taken to clean them.

In natural ſkeletons, the cartilages, ligaments, and ſynovial membranes being all left, the joints poſſeſs their natural mobility. But in order to keep them in this ſtate, they muſt be preſerved in ſpirits, or ſome other fluid capable of preventing the putrefaction of the ſoft parts. This is particularly neceſſary with the ſkeletons of young ſubjects, which are in great part cartilaginous. When a natural ſkeleton is dried, the ſoft parts ſhrink and are ſhrivelled up: the cartilages become contracted, and thus the natural figure is greatly impaired. The contraction of the cartilages diminiſhes the height by an inch or more.

So long as the bones are compoſed of ſeparate pieces, and have more or leſs cartilage in their ſtructure, the oſſeous ſyſtem can only be ſtudied in natural ſkeletons; but when the oſſification is complete, artificial ſkeletons are preferable.

The bones, being the levers by which the motions of the body are performed, have the muſcles or moving powers fixed to them. But as they are ſubſervient, in the conſtruction of our frame, to other purpoſes beſides thoſe of motion, there are ſome bones, though very few, to which no muſcles are attached: ſuch are the incus in the ear, the ethmoid and inferior turbinated bones, and ſome bones of the carpus.

Although the form of the bones is variouſly modified, according to the figure of the parts in which they are placed, or to their deſtinations, they may be claſſed under the three diviſions of broad or flat bones, cylindrical bones, and ſhort bones. The broad bones repreſent flat ſhells, and conſiſt of an inner ſtratum of reticular or ſpongy bony ſubſtance, which is covered on its ſurfaces with thicker or thinner plates of compact bony matter. The cylindrical, or long bones, form long ſhafts, expanded at their extremities into thicker heads, and containing a medullary cavity internally. The ſhort bones are ſuch as are nearly equal in their length, breadth, and thickneſs; variouſly ſhaped, according to their ſituations and offices; and conſiſt of the looſe ſpongy texture, covered by a thin rind of compact bone.

The long bones belong in general to the locomotive apparatus, where they form levers, moved by the muſcles in various directions: they are all placed in the limbs, where they form a central column, moveable in various directions. They diminiſh in length, and increaſe in number, ſucceſſively from above downwards; from the humerus and femur to the phalanges of the fingers and toes. Hence the upper part of the limbs is characteriſed by extent of motion, the lower by multiplicity and variety of movements.

The broad bones have not much to do with locomotion, except as they afford extenſive ſurfaces for the attachment of muſcles. They compoſe cavities, ſuch as thoſe of the cranium and pelvis, for which their form is well adapted. Several are united to form one cavity, and this circumſtance adds to the ſolidity of the ſtructure, as the effect of external force is loſt in the joints. They are generally concave and convex on their two ſurfaces.

The ſhort bones are found in parts which unite mobility and ſolidity, as the vertebral column, the carpus, and tarſus. They are always of inconſiderable ſize, and therefore are found in large number in the parts which they compoſe. Theſe parts are ſtrong, becauſe external force is loſt in the articulations: they are moveable, becauſe the combinations of ſeveral ſmall motions produce a conſiderable effect.

Of the firſt production of the bones, and their gradual developement while the fœtus remains in utero, and of the nouriſhment and growth of bone in general, an account is given in the articles EMBRYO and BONE: in the latter of which, and in EXTREMITIES, there is a deſcription of their external configurations, and of the diſpoſition of the bony ſubſtance. The organization and properties of the ſyſtem are conſidered under the article BONE. Under MEDULLARY *Syſtem* and CARTILAGE the accounts of theſe ſubjects will be found; and the perioſteum is deſcribed under MEMBRANE.

The ſkeleton is divided into the head, trunk, and extremities or limbs. As almoſt all the bones are formed originally of more than one piece, which ſeparate portions of oſſeous matter gradually come together, and are ultimately conſolidated, the number of diſtinct pieces of bone belonging to the ſkeleton is different at different ages. The following is the number of bones, when the oſſification is complete; that is, about the twentieth year.

I. In the HEAD, conſiſting of the *cranium*, and the FACE, the former is made up of

1 or 2 oſſa frontis,
2 oſſa parietalia,
1 os ſphenobaſilare, or ſpheno-occipitale,
2 oſſa temporum,
2 mallei,
2 incudes,
2 ſtapedes,
1 os ethmoideum.

The latter of

2 oſſa maxillaria ſuperiora,
2 oſſa palatina,
2 oſſa malarum, or zygomatica,
2 oſſa naſi,
2 oſſa lacrymalia,
2 oſſa turbinata inferiora,
1 vomer,
1 maxilla inferior,
32 teeth.

The whole amount of bones of the head is 59 or 60. The five pieces of the os hyoides added to theſe, make 64 or 65.

II. The Trunk, comprehending the ſpine, cheſt, and pelvis, conſiſts of

7 cervical
12 dorſal vertebræ,
5 lumbar
2 or 3 bones of the ſternum,
24 ribs,
1 ſacrum,
4 oſſa coccygis,
2 oſſa innominata.

III. The Extremities.

The upper contain

In the ſhoulders,	2 clavicles, 2 ſcapulæ.
In the arms,	2 humeri.
In the fore-arms,	2 radii, 2 ulnæ.
In the wriſts,	2 oſſa navicularia or ſcaphoidea, 2 oſſa lunaria, 2 oſſa cuneiformia, 2 oſſa piſiformia, or orbicularia, 2 oſſa trapezia, or multangula majora, 2 oſſa trapezoidea, or multangula minora, 2 oſſa capitata, 2 oſſa unciformia, or hamata.
In the metacarpi,	10 oſſa metacarpi.
In the fingers,	10 firſt or metacarpal phalanges, 8 middle or ſecond phalanges, 10 third or unguinal phalanges, 8 ſeſamoid bones.
	72

The lower extremities contain,

In the thighs,	2 femora.
In the legs,	2 tibiæ, 2 patellæ, 2 fibulæ.
In the tarſi,	2 aſtragali, 2 calcanei, or oſſa calcis, 2 oſſa navicularia, 2 oſſa cuneiformia magna, 2 ———————— parva, 2 ———————— media, 2 oſſa cuboidea.
	22
Brought over	22
In the metatarſi,	10 oſſa metatarſi.
In the toes,	10 firſt or metatarſal phalanges, 8 middle or ſecond phalanges, 10 third or unguinal phalanges, 6 ſeſamoid bones.
	66

The whole number of bones will be 259 or 261. There is frequently a ſmall bone of the ſeſamoid kind in the tendon of the external head of the gaſtrocnemius: and a roundiſh bit in the hyo-thyroid ligament. If both theſe ſhould exiſt, we muſt add four to the preceding number.

A complete dry natural ſkeleton of a male ſubject of the middle ſize, weighs from 150 to 200 ounces; that of a female, from 100 to 160 ounces.

Of the bones juſt enumerated, the frontal, ſpheno-occipital, vomer, lower jaw, vertebræ, ſacrum, coccyx, ſternum, and os linguale medium, are ſingle (imparia), and, being placed on the middle line of the body, ſymmetrical; all the others are double, or in pairs (paria); each pair being compoſed of a right and left correſponding bone. Hence the ſtructure of the whole ſkeleton is ſymmetrical; that is, if we imagine a perpendicular line to be drawn through the whole body, from before backwards, it will divide the ſkeleton into two correſponding halves, a right and left; the ſingle bones having their right and left ſides exactly alike.

This obſervation, however, of the ſymmetry of the ſkeleton, is not to be underſtood rigorouſly; ſince the right and left of the double bones, or the right and left ſides of the ſingle ones, are not accurately alike. The right or left bone, or the right or left ſide of a bone, may be longer or ſhorter, broader or narrower, &c. &c. than the other. The vomer is generally bent to one ſide; the internal ſurface of the ſkull ſeldom ſymmetrical. The laſt rib is often an inch longer on one ſide than on the other. The ſternum is ſeldom ſymmetrical; and the cartilages of the ribs are not fixed to it exactly oppoſite to each other. The articulations of the ribs with the ſpine often differ conſiderably on the two ſides. But the ſymmetry of the external form is not diſturbed by theſe differences. If the right ſide of a vertebra is more elevated than the left, the correſponding part of the neighbouring bone, or of the intervertebral cartilage, is accommodated to the deviation; ſo that the perpendicular line of the ſpinal column is not impaired, &c. &c.

The ſingle bones may be regarded as the media of union of the two lateral halves, which conſtitute the ſkeleton: they join together theſe two halves into one ſolid whole. In this reſpect there is a marked difference between the bones and the other organic inſtruments of locomotion, the muſcles. The diaphragm is the only muſcle placed on the median line, and its ſtructure is not ſymmetrical: it belongs in great meaſure to the internal or organic life, and correſponds, in its want of ſymmetry, to the arrangements of the internal organs. The ſkeleton, being the baſis or point of ſupport of the muſcles, as well as of all the other organs, conſtitutes an entire and firm fabric; an attribute which it derives from the ſingle bones, which may be regarded as the key-ſtones of the building. The muſcles, not contributing to the ſolidity of the animal ſtructure, are not united into ſuch a ſingle and firm aſſemblage.

The mode in which the different pieces of the ſkeleton are joined to each other, is conſidered under the article Joint; to which, and to that of Membrane, *Synovial*, we refer for the details regarding the anatomical ſtructure of theſe connections.

The oſteology of the head, including the teeth, is conſidered under CRANIUM; that of the vertebral column under SPINE; of the cheſt under LUNG; of the pelvis under HEAD; and of the limbs under EXTREMITIES. The os hyoides, or linguale, is deſcribed in the article DEGLUTITION. The joints are conſidered together with the bones which they unite; except that the articulation of the lower jaw is deſcribed under DEGLUTITION; and thoſe of the occiput, firſt and ſecond vertebræ, under HEAD.

The obſervation, which we have made of the bones in general, that they influence and determine the form of the ſoft parts, holds good more particularly of the whole ſkeleton. Its form, in all men, and in all ſtages of their life, correſponds ſo entirely to the configuration of their body, that an experienced eye would eaſily determine, from a tolerably preſerved ſkeleton, not only the age and ſex, but the growth and moſt ſtriking characters of bodily formation of the individual to whom it had belonged. Hence it is not enough for an artiſt to know the muſcles: he muſt begin with ſtudying the ſkeleton. However numerous the differences of individual configuration in the human race, ſtill retaining its general character and reſemblance, accurate examination will ſhew us not fewer diverſities in the ſtructure, form, ſize, greater or leſs elegance, and even greater or leſs fineneſs and firmneſs in the grain of the bone, in human ſkeletons, which ſtill preſerve the general character. Beſides theſe endleſs individual traits, diſtinguiſhing each ſkeleton from others, we find very ſtriking differences according to age and ſex.

With reſpect to the former of theſe circumſtances, ſkeletons have been divided into perfect and imperfect; the latter not very well choſen term being applied to fœtuſes, children, and ſubjects in whom the epiphyſes are not yet conſolidated with the bodies of the bones, or converted into true apophyſes; although, in relation to the reſt of the ſtructure, the bones are then as perfect as in the adult. The younger the ſubject, the more cartilage does the ſkeleton contain. Reckoning from the twentieth year backwards, the younger the ſubject the larger is the head, compared to the trunk and limbs; (the head is about one-half of the body, in the ſecond month of utero-geſtation; one-fourth in the ninth month; one-fifth at the age of three years; and one-eighth when the growth is complete:) the ſmaller are the bones of the face, and the larger the organ of hearing, in compariſon to the cranium; the larger are the fontanelles; the flatter is the lower part of the face; the larger the cheſt in relation to the pelvis; the ſhorter the limbs; the larger the clavicles; the ſmoother and flatter the broad bones, and the rounder the cylindrical bones. See Albert Durer on the proportions of the body, particularly at the end of the firſt book; and Sue ſur les Proportions du Squelette de l'Homme examiné depuis l'âge le plus tendre, juſqu'à celui de 25, 60 ans, &c. in les Mémoires préſentés, &c. p. 572.

The male and female ſkeleton differ, not only in the whole combination, or the general impreſſion, from a comparative ſurvey, but alſo in the form and properties of the individual parts. Theſe differences, however, are not clearly perceptible until ſome years have elapſed after birth. The plates of the female ſkeleton in Cheſelden and Sue are not to be compared to the accurate delineations of the male ſkeleton by Albinus. Soemmering has, however, ſupplied the deficiency in his beautiful "Tabula ſceleti feminei juncta deſcriptione," folio. He enumerates the following as the characters of the female. "The female ſkeleton is ſmaller and ſlenderer in all parts than the male. The ratio of the head, including the teeth, to the reſt of the bony ſtructure, is greater than in the male: the numbers are as 1 to 6 in the former, 1 to 8 or 10 in the latter. The circumference of the female ſkull is larger on the firſt view, in ſkeletons of the ſame height. The ſkull is larger in proportion to the face: its foramina, the palatine arch, and the whole cavity of the mouth, are ſmaller. The whole thorax is ſhorter; larger above, as far as the fourth rib, narrower below; more moveable, leſs conical; more convex in front; more diſtant from the pelvis, the interval between the laſt rib and the os innominatum being greater; leſs prominent anteriorly, ſo that when the trunk is ſupine, the ſymphyſis pubis is the higheſt point in the female, the thorax in the male ſubject. Generally, the cartilages of the true ribs are longer in proportion to the bone. The vertebral canal is more capacious, and the lateral openings for the nerves are alſo larger. The ſpinous proceſſes are leſs prominent; the ſternum is ſhorter, ending at the plane of the fourth rib, while it reaches to the plane of the fifth in the male.

"The loins are longer, and the angle between the laſt lumbar vertebra and the ſacrum, conſtituting the promontory, is more acute.

"All the diameters of the pelvis are greater; the criſtæ and tuberoſities of the oſſa innominata further apart; the ſpace between the oſſa pubis wider, and the ligaments of the ſymphyſis conſequently broader, although ſhorter.

"The ſacrum is turned more backwards, ſo that its apex and the coccyx do not project ſo much into the pelvis. The acetabula are farther apart, and hence the unſteady gait of the ſex: they are, however, nearer to the front of the pelvis, ſo that, when in the progreſs of pregnancy the centre of gravity is thrown more forwards, its equilibrium is better preſerved.

"The lower limbs form a more acute angle with the pelvis; the feet are ſmaller.

"The ſhoulders are more ſlanting, and the articulations nearer together; the upper limbs are ſhorter, and the fingers more pointed.

"Female bones are diſtinguiſhed from the male by having fewer aſperities, ſmaller ſpines and protuberances, ſhallower impreſſions, ſmaller articulations, and being on the whole ſmoother and more finely turned. The ſhaft or body of a cylindrical bone is more ſlender, in compariſon to the articular ends; and hence the fact which was ſpecified above, of the greater weight of the head in proportion to the reſt of the ſkeleton.

"The bones are not ſo hard in the female: they have, on the whole, a ſomething peculiar, a feminine character, which is not eaſily deſcribed. Their extremities remain longer cartilaginous.

"The frontal ſinuſes are ſmaller; the interval between them, or the glabella, leſs elevated; and the ſuperciliary arches leſs prominent. All the bones of the face are more ſlender. The figure of the alveolar circle is more elliptical in both jaws; in man more circular. The teeth are ſmaller. The os hyoides more ſlender.

"In the vertebræ, the bodies are longer, and more hollowed at the ſides; the tranſverſe proceſſes are directed more backwards, ſo that the channels on each ſide of the ſpinous proceſſes are deeper. The ſpinous proceſſes are ſharper pointed, ſhorter, and more ſlanting.

"The ribs are more ſlender, and flatter; their margins are conſequently ſharper.

"That the cartilages of the upper ribs are more frequently oſſified; that thoſe of the middle ribs are broader; and thoſe of the lower longer, which has been aſſerted by ſome anatomiſts, does not ſeem clearly made out.

"The firſt bone of the ſternum is longer in compariſon to the ſecond. The latter is more than double the length of the former in the male ſkeleton; but in the female it is often not ſo much as double. It is alſo thicker, in compariſon with the ſecond bone, in the female. Theſe differences are obſervable in the embryo.

“ The lumbar vertebræ are longer and more ſlender; the ſacrum broader and more excavated.

“ The oſſa coccygis are ſmaller, more moveable, and directed more forwards. Some have obſerved, that five of theſe bones are met with more frequently in the female than in the male.

“ The oſſa innominata are broader, flatter, and more expanded horizontally. The angle formed between the deſcending ramus of the pubes and the ſymphyſis is more open. The angle between the oſſa pubis is acute in the male, but of 80° to 90° in the female, where it approaches much more to the figure of an arch.

“ The iſchiatic tuberoſities are larger and ſmoother. The ſpace between the tuberoſity and the acetabulum is ſmaller; the iſchiatic notch more conſiderable; the foramen ovale larger; the notch for the tendon of the obturator externus leſs conſiderable.

“ The clavicles are leſs ſtrongly curved, ſo that the ſcapulæ are thrown backwards; the male clavicles are more arched, and the ſhoulders therefore brought more forwards. In the male ſkeleton, the clavicles are inclined a little downwards, ſo as to form an obtuſe angle with the ſternum; while they form nearly a right angle in the female.

“ The female ſcapulæ are ſmaller, ſlenderer, flatter, and have acuter angles.

“ In the female, the thigh-bones are bent more forwards; the neck forms a greater angle with the body; the internal condyle is larger, more prominent, and longer, in compariſon with the external.”

There are differences in ſome parts of the ſkeleton in the various races of mankind; that is, certain characters by which they can be diſtinguiſhed from each other. The head is the part in which the ſtrongeſt diſtinctive marks are obſervable. We have deſcribed theſe very fully, and entered at length into a conſideration of the way in which they are produced, in the articles Cranium and Man.

The national differences in ſtature, in the ſize, length, and proportion of the limbs, &c. muſt be accompanied with correſponding variations in the bony fabric. But there are no peculiarities of form in the individual bones, no varieties in the configuration of proceſſes, or articular heads and cavities, nor in their mutual adaptation. On this ſubject alſo we refer to the article Man.

The individual diverſities of ſize and form muſt be attended with differences in the ſkeleton. The bones are ſometimes longer, ſometimes thicker. The head may be comparatively large or ſmall; the ſhoulders broad or contracted; the thorax flat or prominent; the vertebral column more or leſs curved; the loins thick or ſlender; the thighs or legs, the fingers and toes, longer or ſhorter, &c.

Food ſeems to have no influence on the ſkeleton.

External cauſes have certainly, in ſome inſtances, influenced particular parts in individuals; as the application of artificial preſſure to the head of the newly born. (See Cranium.) The effect of analogous preſſure in contracting the feet of the Chineſe women, producing anchyloſis of the articulations, and thus rendering theſe inſtruments of locomotion nearly uſeleſs, is well known. Similar effects are produced daily on the feet, in compliance with the prevalent notions of beauty in Europe, under our own eyes.

But a more deſtructive proceſs is that of the tight-laced ſtays of European females, who chooſe to fancy that beauty conſiſts in having the cheſt large above and narrow below, although nature has reverſed theſe proportions. The ribs are contracted; the inferior aperture of the cheſt narrowed; the liver, ſtomach, and other abdominal viſcera, ſubjected to a ſevere and moſt injurious preſſure by this barbarous practice of civilized people. We have ſeen the figure of the thorax quite altered by this practice; the lower ribs being puſhed in on the liver, and having left deep indentations in that organ. See Sömmerring’s German treatiſe on this ſubject: “ Von der Schädlichkeit der Schnurbrüſten.”

The effect of artificial cauſes in modifying the form, has, however, been much exaggerated: the round ſhape of the ſkull in the Turks being aſcribed to their turbans, &c. A change is only to be effected by conſiderable and continued preſſure on the bones in their growing ſtate. Theſe alterations are merely individual; they do not affect the race; as the offspring are born with the ordinary formation and characters of the ſpecies. See Man.

For the anatomy of the ſkeleton, ſee Cheſelden's Oſteographia, or the Anatomy of the Bones, fol.; Traité d'Oſteologie, traduit de l'Anglois de Mr. Monro, &c. par Mr. Sue, 2 vols. fol.; C. J. Trew, Tabulæ Oſteologiæ, 1767, fol.; Albinus de Oſſibus Corporis Humani, 1726, 8vo.; Albinus de Sceleto Humano, 1762, 4to.; Albinus Tabulæ Sceleti & Muſculorum, 1747, fol.; Albinus Tabulæ Oſſium, 1763, fol.; Albinus Icones Oſſium Fœtus, 1737, 4to.; Albinus Annotationes Academicæ, 4to.; Soemmerring Tabula Sceleti Feminei, juncta Deſcriptione, fol.; Soemmerring de Corporis Fabrica, t. i.; J. G. Walter von trocknen Knochen, 1763, 8vo.; J. F. Blumenbach, Geſchichte und Beſchreibung der Knochen, 1786, 8vo.; Bertin Oſteologie, 4 tom. 8vo.; Boehmer Inſtitutiones Oſteologicæ, 8vo.

We have, in the Philoſophical Tranſactions, an account of a human ſkeleton, all the bones of which were ſo united, as to make but one articulation from the back to the os ſacrum, and downwards a little way. On ſawing ſome of them, where they were unnaturally joined, they were found not to cohere throughout their whole ſubſtance, but only about a ſixth of an inch deep all round. The figure of the trunk was crooked, the ſpine making the convex, and the inſide of the vertebræ the concave part of the ſegment. The whole had been found in a charnel-houſe, and was of the ſize of a full-grown perſon.

SKELETON, *Vegetable.* The preparations of leaves, fruits, roots, &c. called vegetable ſkeletons, are made in this manner. Chooſe for this purpoſe the leaves of trees or plants, which are ſomewhat ſubſtantial and tough, and have woody fibres, ſuch as the leaves of orange, jaſmine, bay, laurel, cherry, apricot, peach, plum, apple, pear, poplar, oak, and the like; but avoid ſuch leaves as have none of the woody fibres, which are to be ſeparated and preſerved by this method; ſuch are the leaves of the vine, lime-tree, and the like. The leaves are to be gathered in the months of June or July, and ſuch to be choſen as are ſound and untouched by caterpillars, or other inſects. Theſe are to be put into an earthen or glaſs veſſel, and a large quantity of rain-water to be poured over them; and after this they are to be left to the open air, and to the heat of the ſun, without covering the veſſel. When the water evaporates, ſo as to leave the leaves dry, more muſt be added in its place: the leaves will by this means putrefy, but they require a different time for this; ſome will be finiſhed in a month, and others will require two months or longer, according to the hardneſs of the parenchyma of them. When they have been in a ſtate of putrefaction ſome time, the two membranes will begin to ſeparate, and the green part of the leaf to become fluid: then the operation of clearing is to be performed. The leaf is then to be put upon a flat white earthen plate, and covered with clear water; and being gently ſqueezed with the finger, the membranes will begin to open, and the green ſubſtance will come out at the edges; the membranes muſt be carefully taken off with a finger, and great caution muſt be uſed in ſeparating them near the middle rib. When once there is an opening towards this ſeparation, the whole membrane always follows eaſily: when both membranes are taken off, the ſkeleton is finiſhed, and it is to be waſhed clean with water, and then preſerved between the leaves of a book.

The fruits are diveſted of their pulp, and made into ſkeletons in a different manner. Take, for inſtance, a fine large pear that is ſoft, and not ſtrong; let it be nicely pared without ſqueezing it, and without hurting either the crown or the ſtalk; then put it into a pot of rain-water, cover it, ſet it over the fire, and let it boil gently till it is perfectly ſoft, then take it out, and lay it in a diſh, filled with cold water; then hold it by the ſtalk with one hand, and with the other hand rub off as much of the pulp as you can with the finger and thumb, beginning at the ſtalk, and rubbing it regularly towards the crown. The fibres are moſt tender toward the extremities, and therefore to be treated with great care there. When the pulp is thus cleared pretty well off, the point of a fine penknife may be of uſe to pick away the pulp ſticking to the core. In order to ſee how the operation advances, the foul water muſt be thrown away from time to time, and clean poured on in its place. When the pulp is in this manner perfectly ſeparated, the clean ſkeleton is to be preſerved in ſpirit of wine.

Skeletons of roots which have woody fibres, ſuch as turnips, and the like, muſt be made by boiling the root, without peeling it, till it be ſoft, that the pulp may be ſqueezed away by the fingers in the ſame manner, in a diſh of water. Many kinds of roots are thus made into elegant ſkeletons, and the ſame method ſucceeds with the barks of ſeveral kinds of trees; which, when thus treated, afford extremely elegant views of their conſtituent fibres. Philoſ. Tranſ. N° 416.

SKELIGS, *The Three*, in *Geography*, iſlands in the Atlantic ocean, about 7 miles W. of Bolus Head, county of

Kerry, Ireland, one only of which, the Great Skelig, is inhabitable. On this there was formerly an abbey; but it was removed to Ballinaſkeligs, as a more convenient ſituation. See BALLINASKELIGS.

SKELL, a river of England, which runs into the Ure, near Rippon, in Yorkſhire.

SKELLENBERG, a mountain of Bavaria, near Donauwert, where the French and Bavarians were defeated by the duke of Marlborough and prince Lewis of Baden.

SKELLFLETE, a river of England, which runs into the Humber, 12 miles W. of Hull.

SKELLINGE, a town of Sweden, in the province of Halland; 20 miles S.S.E. of Konſback.

SKEMLIK. See KEMLIK.

SKENEATELES, a handſome poſt-village of America, in the ſtate of New York, in Marcellus, Onondaga county, at the outſet of the lake of the ſame name; 163 miles N. of W. from Albany. It has 60 houſes, a handſome Preſbyterian church, ſeveral mills, &c. on Skeneateles creek; and it has a briſk trade.

SKENEATELES *Lake*, a lake about fifteen miles long, and from half a mile to a mile and a half wide, principally in Onondaga county; ſix miles at its north end being in the townſhip of Marcellus. Its trout and ſalmon trout are very large. The outlet is at the north end near the village of the ſame name, and the creek runs north, through Marcellus and Camillus, about ten miles to Seneca river, affording many fine ſeats for mills. Skeneateles, in the dialect of the Onondaga Indians, ſignifies long; and hence the name of the lake.

SKENECTADY. See SCHENECTADY.

SKENEK. See SCHENCK.

SKENESBOROUGH, a town of America, in Waſhington county, in the ſtate of New York, ſituated on Wood creek, on the ſouth ſide of lake George; burned by the Americans in 1777, with their baggage and military ſtores, when they were retreating before the Britiſh army under general Burgoyne. See WHITEHALL.

SKEOTISVAY ISLE, one of the Hebrides, in the pariſh of Harris, and ſhire of Inverneſs. It is about a mile long, and till of late years was uninhabited.

SKEP, in *Agriculture*, a coarſe round farm baſket. It is alſo provincially uſed to ſignify a bee-hive.

SKEPLE, or SKUTTLE, a ſort of flat broad baſket for winnowing corn.

SKER POINT, in *Geography*, a cape on the coaſt of South Wales, in the Briſtol Channel. N. lat. 51° 27′. W. long. 3° 42′.

SKERAT, a rock in the Caledonian ſea, near the weſt coaſt of Skye. N. lat. 57° 24′. W. long. 6° 40′.

SKERENIZ, a town of Bohemia, in the circle of Chrudim; 5 miles N. of Hohemaut.

SKERGULE, a rocky iſland near the ſouth-weſt coaſt of Mull. N. lat. 56° 18′. W. long. 6° 21′.

SKERIVORE ISLES, a cluſter of ſmall iſlands, belonging to the Hebrides, Scotland; ſituated about 40 miles weſtward from the point of Mull.

SKERN, a river of England, in the county of Durham, which runs into the Tees.

SKERPING, a town of Sweden, in Upland; 38 miles N. of Upſal.

SKERRIES, a conſiderable fiſhing-town on the eaſt coaſt of Ireland, in the county of Dublin, near which are ſeveral ſeats and villas. Oppoſite to it are ſome rocks, called Skerries, from which much kelp is procured. There are other iſlands of the ſame name off the coaſt of the county of Antrim, near Portruſh.

SKERRIES, *The*, or *The Skerry Iſles*, a cluſter of ſmall iſlands, ſituated to the eaſtward of the Mainland of the Shetland iſles, to which they belong. The principal of them, and the only ones inhabited, are Bruray, Grunay, and Houſay, which united contain about a hundred inhabitants, who are chiefly employed in fiſhing. Theſe iſlands afford good anchorage for ſmall veſſels; but the want of a light-houſe renders the navigation in their vicinity very dangerous, and has been the occaſion of many melancholy ſhipwrecks. Carliſle's Topographical Dictionary of Scotland, 4to. 1813. Sinclair's Statiſtical Account of Scotland, vol. vi. 8vo. 1794.

SKERRIES, *Iſle of*, a ſmall iſland, included in the pariſh of Llan Fair yn Ghornwy, cwmwd of Tâl-y-bolion, cantraef of Cemmaes, (now called the hundred of Tâl-y-bolion,) and county of Angleſea, North Wales, is ſituated at the diſtance of a mile and a half from the Mainland, and affords paſturage for a few ſheep. The foſſile ſtone called *aſbeſtos*, is found here in great abundance; and at one extremity of the iſland is an excellent light-houſe, which is highly ſerviceable to veſſels navigating between Ireland and the ports of Cheſter and Liverpool. The Welſh call this iſland Ynys y Mael Rhoniaid, *i. e.* the Iſle of Seals. Carliſle's Topographical Dictionary of Wales, 4to. 1811.

SKERSTA, a town of Sweden, in Smaland; 10 miles N.N.E. of Jonkioping.

SKESMO, a town of Norway, in the province of Chriſtiania; 14 miles E.N.E. of Chriſtiania.

SKETHYE, a river of North Wales, in the county of Merioneth, which runs into the Iriſh ſea, 3 miles N.N.W. of Barmouth.

SKEUDITZ. See SCHKEUDITZ.

SKEVERI, a town of Hindooſtan, in Viſiapour; 10 miles S.W. of Raibaug.

SKEW, or SKILE, *Facets*, among *Jewellers*. See FACETS.

SKEWRING CHEESE, in *Agriculture*, the practice of thruſting ſtrong iron-wire ſkewers into cheeſes, in order to draw off and diſcharge the whey from them. The ſkewers for this uſe are moſtly about eighteen or twenty inches in length. See DAIRYING.

SKEYL, provincially to lean on one ſide, or throw up, as in unloading a cart.

SKEYL-*Beaſt*, in *Rural Economy*, provincially the partition of cattle-ſtalls.

SKEYLD, provincially parti-coloured, as geeſe, ducks, &c.; or ſhelled.

SKIALFAND'EFIORD, in *Geography*, a river of Iceland, which receives the waters of a large and rapid river called the Skialfandèfliot, and alſo a river called Laxaa, which flows from the lake Myoatn. Huſavik, a commercial ſtation, lies on this river, N.E. of Eyafiord. Here is no good fiſhing; but many ſeals are caught during winter. Eider-ducks are very abundant on the coaſt.

SKIATIC STAY, in *Rigging*, a contrivance for hoiſting and lowering burdens out of or in ſhips, which clinches or makes faſt with two half-hitches, and the ends ſtopt, round the heads of the main and fore-maſts, with a tackle depending from it over the hatchway.

SKIATO, in *Geography*, one of the Grecian iſlands, neareſt to the coaſt of Greece, ſeparated from the iſland of Scopoli only by a channel of about two leagues, and from the main land by one not much wider. Anchorages, rather numerous and ſafe, are to be found along the eaſt coaſt, and between the ſmall iſlets which are on the ſame ſide. To this circumſtance the advantages of this little iſland are nearly reduced.

SKIBBEREEN, a poſt-town of the county of Cork, Ireland, formerly called Stapletown. It is ſituated on the ſouth ſide of the river Ilen, which flows into Baltimore harbour. This river is navigable nearly from Skibbereen for lighters; yet the trade is chiefly carried on by land-carriage, becauſe the general prevalence of weſterly winds renders the communication by ſea always uncertain, and often tedious. Skibbereen, ſays Mr. Townſend, without patronage or encouragement, has, from the mere circumſtance of its ſituation, become populous, thriving, and wealthy. At its markets and fairs, beſides the other uſual articles of merchandize, very large quantities of coarſe linens and yarn are expoſed to ſale. The town is, notwithſtanding, ill built, with a number of wretched cabins, and very dirty. It is 160 miles S.W. from Dublin, and 38 W. by S. from Cork. Townſend's Statiſtical Survey.

SKICIE, a town of European Turkey, in Moldavia; 40 miles W. of Jaſſy.

SKID, in *Rural Economy*, a term applied to the chain by which the wheel of a waggon is faſtened, ſo as to prevent its turning round, upon deſcending a ſteep hill. See Drag.

Skid-*Beams*, in *Ship-Building*, are the beams in the waiſt, which connect the forecaſtle with the quarter-deck.

Skids, *Boat*, ſquare pieces of timber bolted one on each ſide, and projecting over the ſtern, with ſheaves in their outer ends to hoiſt the boat up. Boat-ſkids over the quarters are fixed at the heel, and ſuſpended by a lift at the head; the latter of iron lately in the navy.

Skids, *Whale*, are long ſquare pieces of timber, projecting from the ſides of Greenland ſhips, for the convenience of hoiſting and canting the whale out of the water.

SKIDDAW, in *Geography*, a mountain of Cumberland, England, is remarkable as being claſſed among the greateſt eminences of the iſland. It is alſo diſtinguiſhed for its romantic and grand ſcenery, as well as for the lakes in its different hollows, and near its baſe. Maurice, in his poem of "Netherby," thus characteriſes this auguſt mountain:

"There, tow'ring Skiddaw, wrapt in awful ſhade,
Monarch of mountains, rears his mighty head;
Dark'ning with frowns fair Keſwick's beauteous vale,
He views beneath the gathering tempeſts ſail,
Secure, nor heeds the rolling thunder's rage,
Though Schruffel, trembling, marks the dire preſage."

According to the trigonometrical ſurvey, by colonel Mudge and his aſſiſtants, it is ſtated that the higheſt point of Skiddaw is 3022 feet above the level of the ſea. Seafell, in the ſame county, is 3166 feet in height. Like the generality of mountains in this part of the kingdom, Skiddaw conſiſts of numerous inequalities; deep hollows, and bold crags; irregular fiſſures, and gentle ſlopes. Its ſurface alſo preſents a variety of ſubſtances, colours, and forms. In ſome places are vaſt maſſes of bare rock; in other parts, a ſoft ſhort graſs preſents itſelf; and in others are heath, furze, and brambles. Wildneſs and grandeur are the general features. Mrs. Radcliffe gives a very intereſting deſcription of different parts of this mountain, in her "Journey through Holland," &c. 2 vols. 8vo. 1795. Other accounts are given in the following works: Hutchinſon's Excurſion to the Lakes, 8vo. 1776; Weſt's Guide to the Lakes, 8vo. 1802; Gilpin's Obſervations relative chiefly to pictureſque Beauty on the Mountains and Lakes of Cumberland and Weſtmoreland, 2 vols. 8vo. 1786.

SKIERENDAL, a town of Norway, in the province of Aggerhuus; 20 miles N.W. of Chriſtiania.

SKIERN, a river of Denmark, which runs into the ſea, 12 miles S. of Ringkiobing.

SKIFF, a boat much uſed in the river Thames. It differs from a wherry by being ſhorter and broader in proportion, and having a tranſom abaft.

SKIFFI, in *Geography*, a ſmall iſland in the Grecian Archipelago. N. lat. 38° 44′. E. long. 24° 13′.

SKILI, a town of Aſiatic Turkey, in Natolia; 48 miles E.N.E. of Conſtantinople.

SKILLING, in *Rural Economy*, a term ſignifying an iſle, or bay of a barn; alſo a ſlight addition to a cottage.

SKILLINGE, in *Geography*, a town of Sweden, in the province of Blekingen; 4 miles W. of Carlſcrona.

SKILLINGS, a river of America, in the diſtrict of Maine, which runs into the ſea, 4 miles W. of New Briſtol.

SKILSKIOER, a ſea-port of Denmark, in the iſland of Zealand, in a bay which communicates with the Great Belt; 48 miles S.W. of Copenhagen. N. lat. 55° 16′. E. long. 11° 27′.

SKILUGRUND, a ſmall iſland on the eaſt ſide of the gulf of Bothnia. N. lat. 63° 55′. E. long. 20° 50′.

SKIM-Coulter, in *Agriculture*, a ſort of coulter invented by Mr. Ducket, for paring off the ſurface of coarſe graſs or other lands, and placing it in the bottom of the furrow, ſo as to be fully covered and ſecured. It has been uſed in different diſtricts with the greateſt advantage and ſucceſs. It is ſtated in the Agricultural Report of Hertfordſhire, that Mr. Biggs, near St. Albans, finds it of excellent effect in clover lays, and alſo wherever any rubbiſh is on the land that wants burying, as well as in breaking up old ſaintfoin lays. And it may be beneficially employed on many other occaſions.

Skim-*Coulter Plough*, that ſort of plough which has a ſkim-coulter of ſome kind or other attached to it. See Plough.

Skim-*Milk*, in *Rural Economy*, that ſort of milk which is left, after the cream has been taken away or ſkimmed off from the ſurface of it. This proceſs is moſtly performed by means of a ſlight thin ſkimming-diſh, after the milk has been ſet by for ſome time in ſhallow veſſels, either in its natural ſtate, or when having undergone, in ſome caſes, the operation of ſcalding. Where the latter practice is followed, though it might at firſt be reaſonably ſuppoſed that all the oily unctuous matter of the milk would be brought to the ſurface, yet it is found by experience that that is not the caſe; but that, on the contrary, the ſcalded ſkimmed-milk is much richer, and better even for the purpoſe of ſuckling calves, as well as capable of making far better cheeſe than the raw ſkimmed-milk. In Devonſhire, the ſcalded ſkim or ſkimmed-milk is eſtimated at the value of a penny farthing the quart, either for the uſe of cheeſe-making, or that of feeding hogs.

The ſkim-milk in the county of Eſſex, as well as in many others, eſpecially thoſe more towards the north, is converted to the purpoſe of keeping and fattening porkers, and that of being diſpoſed of, at the rate of about three-pence or four-pence the gallon, to the lower claſſes of the people; or that of taking in pigs to keep, at the price of about from three ſhillings and ſixpence to four ſhillings and ſixpence the week. A hog has been known to be fattened, in the above named diſtrict, in this way, to the weight of ſixty-ſix ſtone, without the offal, at eight pounds to the ſtone, ſkim-milk only being given for the purpoſe.

In other diſtricts, the farmers rear and bring up their calves, and keep their own hogs, on this ſort of milk, as well as prepare cheeſe from it, finding theſe the moſt profitable applications of it.

The reſult of a number of trials has ſhewn, that in forming ſkim-milk, about ten ounces of butter is taken from twelve pints of milk, under the ſcalding practice. See DAIRYING.

SKIM-*Milk Cheeſe*, that ſort of cheeſe which is made from ſkim or ſkimmed-milk. It is moſtly a poor inferior ſort of cheeſe, though much of it is made in different diſtricts of the kingdom. It is, however, frequently a practice to take away the cream from only a certain portion of the milk that is intended for cheeſe, as that of the night meal, &c. In Devonſhire, when cheeſe is to be made, much care is taken that the milk be not heated ſo far as to produce bubbles under the cream, which is firſt to be taken off from it, or when it is to be uſed with it.

SKIMMER, in *Ornithology*. See RYNCHOPS.

SKIMMIA, in *Botany*, a name adopted by Kæmpfer from its Japaneſe vernacular appellation, *Mijanea Skimmi*.—Kæmpf. Amœn. faſc. 5. 779. Thunb. Nov. Gen. 57. Fl. Japon. 4. Schreb. 81. Willd. Sp. Pl. v. 1. 671. Mart. Mill. Dict. v. 4. Juſſ. 425.—Claſs and order, *Tetrandria Monogynia*. Nat. Ord. *Plantæ incertæ ſedis;* Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, very ſmall, permanent, cloven nearly to the baſe into four, ovate, acute ſegments. *Cor.* Petals four, ovate, concave, minute. *Stam.* Filaments four, very ſhort; anthers ...... *Piſt.* Germen ſuperior, roundiſh; ſtyle ſolitary; ſtigma ...... *Peric.* Berry ovate, umbilicated, ſlightly furrowed, ſmooth, full of mealy pulp, and ſplitting imperfectly into four parts. *Seeds* four, nearly triangular or convex externally, oblong, white.

Obſ. The Perianth is occaſionally cloven into five ſegments.

Eſſ. Ch. Petals four, concave. Calyx four-cleft. Berry with four ſeeds.

1. S. *japonica*. Japaneſe Skimmia. Thunb. Japon. 62. Kæmpf. Ic. Select. t. 5.—Native of Japan, near Nagaſaki, ripening its fruit in December. *Stem* ſhrubby, erect, ſmooth. *Branches* alternate, nearly ſquare. *Leaves* at the ſummits of the branches, alternate, ſtalked, numerous, oblong, undulated, entire, ſlightly notched towards the tip, erect, about a finger's length, with a reflexed margin; green and rugoſe above; pale and dotted beneath. *Footſtalks* convex beneath, flat above, thickiſh, ſhort. *Flowers* white, on round, thickened ſtalks, in terminal panicles.

The foliage is evergreen, and has an aromatic flavour.

SKIMMING-DISH, in *Rural Economy*, that ſort of light thin-edged diſh, which is employed in ſkimming the cream off the ſurface of milk, in the practice of the dairy. Diſhes of this kind are made either of hard wood or tin, being formed in a nice, thin, light manner, with fine ſharp edges. See DAIRYING.

SKIMMING-*Spade*, in *Agriculture*, that ſort of ſharp-mouthed ſpade which is employed in ſkimming or paring off the graſſy ſurface, or ſward of land, which is intended to be burnt. See PARING and BURNING.

SKIN, in *Anatomy*, a large thick membrane, ſpread over the whole body, ſerving as the external organ of feeling, and as a covering and ornament of the parts underneath. See INTEGUMENTS.

SKIN, *Diſeaſes of the*. See CUTANEOUS *Diſeaſes;* where an outline of the claſſification of theſe maladies, deviſed by the late ingenious Dr. Willan, by whom the pathology of theſe neglected and undiſtinguiſhed diſorders has been greatly elucidated, will be found. For more particular information, conſult the articles LEPROSY, LICHEN, PSORIASIS, PORRIGO, HERPES, &c. and Dr. Bateman's Pract. Synopſis of Cutaneous Diſeaſes, according to the arrangement of Dr. Willan.

SKIN, in *Rural Economy*, the hide of an animal. The refuſe and waſte of it which are cauſed by the different manufactures, and which ariſe in the various purpoſes to which it is applied, are capable of forming very uſeful manures, when they are in any ſuitable quantity; ſuch as the chips of the ſhoemaker, the dreſſings and trimmings of the currier, the clippings of the farrier, and the waſte offal matters of the tan-yard as well as the glue manufactory.

It has been ſuggeſted by the writer of the work on "Agricultural Chemiſtry," that the gelatine which is contained in every kind of ſkin is in a ſtate fitted for its gradual ſolution or decompoſition; and that when buried in the ſoil, it laſts or continues for a conſiderable time, and conſtantly yields a ſupply of nutritious matter to the plants, which are placed within the neighbouring range of its action. All waſte matters of this nature ſhould therefore be carefully preſerved for the purpoſe of being applied as manures.

SKIN, in *Commerce*, is particularly uſed for this membrane ſtripped off the animal, to be prepared by the tanner, ſkinner, currier, parchment-maker, &c. and converted into leather, &c.

The uſe of ſkins is very ancient; the firſt garments in the world having been made of them. The Danes and other northern nations have a long time dreſſed themſelves in ſkins. Moroccoes are made of the ſkins of a kind of goats. (See MOROCCO.) Parchment is uſually made of ſheep-ſkins; ſometimes of goat-ſkins. (See PARCHMENT.) Velom is a kind of parchment made of the ſkin of an abortive calf, or at leaſt of a ſucking calf. (See VELOM.) The true ſhammy is made of the ſkin of an animal of the ſame name; though frequently it is counterfeited with common goats' and ſheep-ſkins. See SHAMMY.

The Indians in Carolina and Virginia dreſs buck and doe-ſkin in this manner: the felt being taken off, they ſtrain them, with lines or otherwiſe, much like the clothiers' racks, in order only to dry them. When the hunting time is over, the women dreſs the ſkins, by putting them in a pond or hole of water, to ſoak them well; then with an old knife, fixed in a cleft ſtick, they force off the hair whilſt they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deer's brains, dried and preſerved for this purpoſe, is put along with them; this veſſel is ſet on the fire till they are more than blood-warm, which will make them lather and ſcour clean; after this, with ſmall ſticks, they wreſt and twiſt each ſkin, as long as they find any wet to drop from them, letting them remain ſo wreſted for ſome hours, and then they untwiſt and ſtretch each of them in a ſort of rack, ſo that every part is extended, and as the ſkin dries, they take a dull hatchet, or ſome ſuch inſtrument, and rub them well over to force all the water and greaſe out of them, till they become perfectly dry, and then their work is done.

In this manner one woman (for the men never employ themſelves in this work) will dreſs eight or ten ſkins in a day, that is, begin and finiſh them. Phil. Tranſ. No. 194. See BUFF.

For the manner of preparing ſhagreen, ſee SHAGREEN.

SKINS, *lacquering and gilding*. See LACQUER.

SKINK. See SCINCUS.

SKINKER, a cup-bearer, or butler. See ARCH *Butler*.

SKINNER, STEPHEN, in *Biography*, an antiquary, was born about the year 1622, in or near London. He received his academical education at Chriſt-church college, Oxford, in the year 1638, but the civil war cauſed him to leave the univerſity without taking a degree. He thence travelled on the continent, and ſtudied at various univerſities. On his return to his native country, he went to Oxford, and took his degree in arts, and then ſettled as a phyſician at Lincoln, where he died in 1667. He was a man of very extenſive erudition, but is chiefly known by his works in etymology, which, after his death, came into the hands of Mr. Thomas Henſhaw, who digeſted, corrected, and enlarged them, and publiſhed them in 1671, with the title of "Etymologicon Linguæ Anglicanæ;" a work that has always been conſidered as of high authority among the learned, and is ſtill regarded as a moſt uſeful book of reference.

SKINNERA, in *Botany*, Forſt. Gen. t. 29, was ſo named in honour of Mr. Skinner, an Oxford gentleman, whom Forſter terms "a moſt acute and clear-ſighted botaniſt," but we have met with no record of him elſewhere; and the genus thus denominated is in no reſpect different from FUCHSIA; ſee that article. By the ſpecific name, *excorticata*, the author ſeems to have had a punning alluſion in his mind.

SKINNERS, *Company of*. See COMPANY.

SKINNING, in *Ship-Building*, a term often uſed for planking the bottom.

SKINOSA, in *Geography*, a deſart iſland, or rather rock, in the Grecian Archipelago, about 12 miles in circumference; 5 miles S. from the iſland of Naxia. N. lat. 36° 55′. E. long. 25° 32′.

SKINSKATTEBERG, a town of Sweden, in Weſtmanland; 25 miles N.N.W. of Stroemſholm.

SKINTEI, a town of European Turkey, in Moldavia; 10 miles S. of Jaſſi.

SKINUS, σχινος, a name given by the ancient naturaliſts to the lentiſk-tree, and alſo to a peculiar ſpecies of the ſquill, or ſcilla, which was not nauſeous and emetic as the common ſquill, but eſculent and pleaſant to the taſte.

SKIOLDS, in *Geography*, a town of Norway, in the province of Bergen; 32 miles N. of Stavanger.

SKION, a town of Sweden, in Medelpadia, near the coaſt of the gulf of Bothnia. The church was formerly a caſtle, and the ſteeple is full of loop-holes for arms; 30 miles S. of Hernoſand.

SKIPNESS POINT, a cape of Scotland, on the E. coaſt of Kintyre, with a village called Skipneſs; 22 miles N. of Cambletown. N. lat. 55° 49′. W. long. 5° 24′.

SKIPPACH CREEK, a creek of America, in the Delaware, where general Waſhington was encamped before the battle of German Town, in the county of Montgomery.

SKIPPACK, a townſhip of Pennſylvania; 20 miles N. of Philadelphia. Shippack and Perkiomen contain 902 inhabitants.

SKIPPER. See SHIPPER.

SKIPPER, an Engliſh name for the common gar-fiſh. See ACUS.

SKIPPON, in *Geography*, a river of England, in the county of Lancaſter, which runs into the Wyre.

SKIPSILAR, a town of European Turkey, in Romania; 72 miles E. of Emboli.

SKIPTON, or *Skipton in Craven*, a market-town in the eaſt diviſion of the wapentake of Staincliffe and Ewcroſs, Weſt Riding of the county of York, England, is ſituated at the diſtance of 48 miles W. by S. from the city of York, and 216 miles N.N.W. from London. This town, which previouſly was a poor place, has, ſince the incloſure of Knareſborough foreſt, become the chief mart for the diſtrict of Craven. The market-day is Saturday, weekly; when there is always a large ſupply of different ſorts of grain, which is thence diſperſed throughout Craven, and the manufacturing country in the north-eaſt part of Lancaſhire. Brown, in his Agricultural Survey of the Weſt Riding of the County, affirms that upwards of two hundred carts regularly attend this market. The fairs here are numerous, *viz.* on the firſt Saturday after old Twelfth-day, the 13th of March, the Saturday before Palm-Sunday, the Tueſday in Eaſter-week, and every other Tueſday till Whitſuntide, chiefly for lean cattle; Saturday before Whitſun-eve, and Saturday before Trinity Sunday, old St. James, old Martinmas, beſides fortnight fairs every other Tueſday throughout the year for fat cattle, ſheep, &c.

Skipton ſtands cloſe to the Leeds and Liverpool canal, a circumſtance which greatly facilitates its trade. It conſiſts chiefly of one very wide and long ſtreet, where the markets are held, with ſeveral ſtraggling lanes on each ſide of it. The church, which is ſituated at one extremity of the main ſtreet, is a ſpacious ſtructure, with a tower at the weſt end, which appears, from an inſcription thereon, to have been rebuilt, in 1655, by the celebrated Ann Clifford, counteſs of Dorſet, Pembroke, and Montgomery. Here are inſcriptions, on plain ſtones, in memory of the three firſt earls of Cumberland.

Skipton caſtle ſtands at a ſhort diſtance to the eaſtward of the church, and on the left ſide of the road leading to Knareſborough. This ancient ſtructure is ſaid to have been originally erected ſoon after the Conqueſt by Robert de Romeli, then lord of the honour of Skipton, whoſe daughter and heireſs carried it by marriage to William Fitz-Duncan, earl of Murray. From his family it paſſed in the ſame manner to William le Gros, earl of Albemarle, and afterwards ſucceſſively to William de Mandeville, earl of Eſſex, to Baldwin de Betun, and to William de Fortibus. In the reign of Richard I. Avelin, daughter to the ſecond William de Fortibus, a minor, ſucceeded, and became ward to king Henry III., who, in 1269, gave her in marriage to his ſon Edmund, earl of Lancaſter. On the forfeiture of her ſon, earl Thomas, for rebellion againſt king Edward II. the caſtle was granted, in 1309, to Robert de Clifford, a Herefordſhire baron, whoſe deſcendants, earls of Cumberland, continued to enjoy it till the early part of the ſeventeenth century, when it devolved to Richard Sacville, earl of Dorſet, by his marriage with Ann Clifford, the diſtinguiſhed lady above-mentioned. By her daughter and heireſs, Margaret, it was conveyed to John Tufton, ſecond earl of Thanet, in whoſe family it yet remains.

Skipton caſtle, though apparently little calculated for defence againſt the engines of modern warfare, appears to have been of conſiderable importance during the civil wars between king Charles and his parliament. It was firſt garriſoned in the royal cauſe, and is ſaid to have held the ſurrounding country for ſome time in great awe. At length, however, it was vigorouſly beſieged by a detachment of the parliamentary army, to whom it ſurrendered upon honourable terms on the 20th of December, 1645. In the following year, its works and defences were deſtroyed by order of parliament. Lady Clifford, after the death of her ſecond huſband, the earl of Pembroke, repaired this caſtle, in which ſhe was born, and made it occaſionally the place of her reſidence. Though not much elevated above the ſurrounding country, it nevertheleſs commands a pleaſing view over the town and vale of Skipton, which is one of the fineſt and moſt fertile in England, extending about twelve miles in length, and from one and a half to two miles in breadth. It contains little tillage, but diſplays the moſt luxuriant meadows and paſtures that can any where be ſeen.

Skipton, according to the parliamentary returns for 1811, contains 609 houſes, and 2868 inhabitants. The pariſh is of great extent, and is partly comprehended in Claro wapentake. Beauties of England and Wales, vol. xvi. by John Bigland, 1812. Pennant's Tour in Scotland, 4to. 1790. Whitaker's Hiſtory, &c. of Craven, 4to. 1805.

Skipton, a town of America, in Maryland, on the Potomack; 11 miles S.E. of Fort Cumberland.

SKIRINGLASS, a ſmall iſland near the W. coaſt of Scotland. N. lat. 58° 2′. W. long. 5° 10′.

SKIRINTARSAN, a ſmall iſland near the E. coaſt of Skye. N. lat. 57° 19′. W. long. 5° 33′.

SKIRKY, a cluſter of ſmall iſlands in Kenmare river, on the S.E. coaſt of Kerry; 5 miles E. of Lamb's Head.

SKIRMISH, in *War*, a diſorderly kind of combat, or encounter, in preſence of two armies, between ſmall parties, or perſons, who advance from the body for that purpoſe, and introduce to a general, regular fight.

The word ſeems formed from the French, *eſcarmouche*, which ſignifies the ſame, and which Nicod derives from the Greek χαρμη, which ſignifies, at the ſame time, both *light*, *combat*, and *joy*. Menage derives it from the German, *ſchirmen* or *ſhermen*, *to fence* or *defend*: Du Cange, from *ſcarramuccia*, a *light engagement*, of *ſcara* and *muccia*, a body of ſoldiers hid in ambuſh; in regard many ſkirmiſhes are performed by perſons in ambuſcade.

Skirmish *Bay*, in *Geography*, a bay on the E. coaſt of Chatham iſland, ſo called from an unhappy diſpute between captain Vancouver's crew and the natives. S. lat. 43° 49′. E. long. 183° 25′.

SKIRO. See Sciro.

SKIRRET, in *Botany*. See Sium.

SKIRRID Vawr, or *Great Skirrid*, in *Geography*, a mountain of Wales, in the county of Monmouth; 2 miles N. of Abergavenny.

SKIRRIES, a rock in the North ſea, near the E. coaſt of Scotland; 2 miles S. of Peterhead.

SKIRTING, in *Agriculture*, a mode of performing the buſineſs of ſod-burning. See Sod-*Burning*.

SKIT, in *Geography*, a town of Walachia, on the Ribnik; 80 miles N. of Buchareſt.

SKITTIKISS, a bay on the E. ſide of Waſhington's iſlands, near the W. coaſt of North America.

SKITTISH, in the *Manege*. A horſe is ſaid to be ſkittiſh, in French *écouteux*, or *retenu*, that leaps inſtead of going forward; that does not ſet out, or part from the hand freely, nor employ himſelf as he ought to do.

SKIVE, in *Geography*, a town of Denmark, in North Jutland; 15 miles N.W. of Viborg. N. lat. 56° 34′. E. long. 9° 1′.

SKLENO, or *Glaſs Huts*, a town of Hungary, celebrated for its warm baths; 5 miles N. of Cremnitz.

SKOBELEKA, a town of Ruſſia, in the government of Irkutſk; 48 miles S.S.W. of Kirenſk.

SKODNY, a town of Sileſia, in the principality of Oppeln, in which is a royal foundery for the caſting of bombs; 10 miles S. of Oppeln.

SKOFDE, a town of Sweden, in Weſt Gothland; 62 miles E. of Uddevalla.

SKOG, a town of Sweden, in the province of Helſingland; 34 miles W.N.W. of Hudwickſwall.—Alſo, a town of Sweden, in Angermanland, on a lake; 20 miles N. of Hernoſand.

SKOKHAM, *Iſle of*, a ſmall iſland ſituated in St. George's Channel, at the diſtance of five miles from St. Anne's Head, in Pembrokeſhire, South Wales. It contains 200 acres, 2 roods and 2 poles of ground, and is the property of John Lloyd of Mabus, eſq. Its products are barley, oats, rye-graſs, and rabbits. Fenton's Tour in Pembrokeſhire, 4to. 1810.

SKOKI, a town of the duchy of Warſaw; 18 miles N. of Poſen.

SKOLEN, or Schohlen, a town of Saxony, in Thuringia; 8 miles S. of Naumburg.

SKOLOMISI, a town of Poland; 25 miles N.E. of Cracow.

SKOLOSCHIA, a town of Ruſſia, in the government of Irkutſk; 44 miles N.E. of Kirenſk.

SKOMAR, *Iſle of*, a ſmall iſland ſituated on the ſouth ſide of St. Bride's bay, off the coaſt of Pembrokeſhire, North Wales. It is divided from the Mainland by a narrow ſtrait, called Jack's Sound. This iſle contains 700 acres of land, a large portion of which is under cultivation, and is moſt prolific in rabbits, 2000 couple being killed annually for ſale. It is the property of Charles Phillips, eſq. of St. Bride's Hill. Fenton's Tour in Pembrokeſhire, 4to. 1810. Carliſle's Topographical Dictionary of Wales, 4to. 1811.

SKOMPE, a town of the duchy of Warſaw; 16 miles N.E. of Wladiſlaw.

SKON, a town of Sweden, in the province of Medelpadia; 3 miles N. of Hernoſand.

SKONE. See Schonen.

SKONGEN, a town of Norway, on the coaſt of Drontheim bay; 26 miles N.N.E. of Drontheim.

SKOPIA, or Uskup, a town of European Turkey, in Macedonia, on the river Varda, the ſee of an archbiſhop; 54 miles N. of Akrida. N. lat. 42° 40′. E. long. 21° 2′.

SKOPIN, a town of Ruſſia, in the government of Riazan; 44 miles S. of Riazan. N. lat. 54°. E. long. 39° 14′.

SKORBY, a town of Sweden, in Schonen; 22 miles S.E. of Lund.

SKOTGRUND, a ſmall iſland on the eaſt ſide of the gulf of Bothnia. N. lat. 62° 17′. E. long. 21° 3′.—Alſo, a ſmall iſland on the weſt ſide of the gulf of Bothnia. N. lat. 60° 39′. E. long. 17° 28′.

SKOTSCHAU, Scholsch, or Skozow, a town of Sileſia, in the principality of Teſchen; 7 miles E.N.E. of Teſchen. N. lat. 49° 47′. E. long. 18° 45′.

SKOVES, in *Agriculture*, provincially reaps, ſhoves, grips, or bundles of unbound up grain; alſo unbound ſheaves of corn.

SKOUT, in *Ornithology*. See Lomwia.

SKRABBA, in *Ichthyology*, a name given by ſome to a fiſh, called by Jonſton and Schoneveldt the *ſcorpius marinus*, but wholly different from the *ſcorpæna* of other authors. See Father-*Laſher*.

SKREED, in *Agriculture*, provincially a border or narrow ſlip of land.

SKREEN. See Screen.

SKREY, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 8 miles S. of Rakonitz.

SKRUBBAN, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 63° 8′. E. long. 18° 34′.

SKRYNE, a ſmall town of the county of Meath, Ireland, which received its name from being ſuppoſed to contain the ſhrine (*ſcrinium*) of St. Columba. There were a caſtle and two abbeys here, of which ſome ruins remain. Skryne is 19½ miles N. by W. from Dublin.

SKRZIWANE, a town of Bohemia, in the circle of Rakonitz; 4 miles S. of Rakonitz.

SKUA, in *Ornithology*. See Cataracta.

This bird inhabits Norway, the Ferro iſles, Shetland, and the noted rock Foula, a little weſt of them. It is alſo a native of the South ſea. It is the moſt formidable gull; its prey being not only fiſh, but the leſſer ſorts of waterfowl,

fowl, as teal, &c. and it is alſo ſaid to prey on ducks, poultry, and even young lambs; it has all the fierceneſs of the eagle in defending its young; when the inhabitants of the Ferro iſlands viſit the neſt, it attacks them with great force, ſo that they hold a knife erect over their heads, on which the ſkua will transfix itſelf in its fall on the invaders. In Foula it is a privileged bird, becauſe it defends the flocks from the eagle, which it beats and pierces with great fury; and the natives impoſe a fine on any perſon who deſtroys one of theſe birds. Pennant.

SKUFE, in *Agriculture*, provincially a precipice or declivity.

SKULA, in *Geography*, a mountain of Sweden, in Angermanland; 10 miles N. of Hernoſand.

SKULL, in *Anatomy*. See Cranium.

Skull, *Injuries of the*, *&c.* See Injuries *of the Head*.

Skull-*Cap*, in *Botany*. See Scutellaria.

Skull-*Cap, Blue*, in *Agriculture*, the common name of a weed which is often found troubleſome on wet boggy grounds, or near the ſides of ponds. It is perennial in its growth, and of courſe more difficult in its removal from land. There is alſo a leſſer ſort, which has the ſame nature and habits of growth. They ſhould both be eradicated from out of the land as much as poſſible.

SKUNK, in *Zoology*. See *American* Pole-*Cat*.

SKUOE, in *Geography*. See Scuoe.

SKUPOPING, a lake of North Carolina. N. lat. 35° 45′. W. long. 76° 42′.

SKUPPERNONG, a river of North Carolina, which communicates by means of a canal with the lake in Diſmal Swamp.

SKURUP, a town of Sweden, in Schonen; 16 miles S.E. of Lund.

SKUSCH, a town of Bohemia, in the circle of Chrudim; 8 miles S.E. of Chrudim.

SKUTERAD, a town of Norway, in Aggerhuus; 22 miles W. of Chriſtiania.

SKUTTOCK Hills, five eminences in Hancock county, on the coaſt of Maine, that ſerve as landmarks for ſailing into Gouldſborough harbour.

SKWERNIOW, a town of Bohemia, in the circle of Kaurzim; 6 miles S. of Kaurzim.

SKWORETZ, a town of Bohemia, in the circle of Kaurzim; 12 miles W.N.W. of Kaurzim.

SKY, the blue expanſe of air or atmoſphere.

The azure colour of the ſky ſir Iſaac Newton attributes to vapours beginning to condenſe therein, which have got conſiſtence enough to reflect the moſt reflexible rays, *viz.* the violent ones; but not enough to reflect any of the leſs reflexible ones.

M. de la Hire attributes it to our viewing a black object, *viz.* the dark ſpace beyond the regions of the atmoſphere, through a white or lucid one, *viz.* the air illumined by the ſun; a mixture of black and white always appearing blue. But this account is not originally his; it is as old as Leonardo da Vinci. See Blueness and Colour *of the Clouds*.

Sky-*Colour*. To give this colour to glaſs, ſet in the furnace a pot of pure metal of frit from rochetta, or barilla, but the rochetta frit does beſt; as ſoon as the metal is well purified, take for a pot of twenty pounds of metal ſix ounces of braſs calcined by itſelf; put it by degrees, at two or three times, into the metal, ſtirring and mixing it well every time, and diligently ſcumming the metal with a ladle; at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole ſtand twenty-four hours longer in the furnace, and it will then be fit to work, and will prove of a moſt beautiful ſky-colour. Neri's Art of Glaſs, p. 40.

Sky-*Flower*, in *Botany*. See Cineraria.

Sky-*Rocket*. See Rocket.

SKYE, in *Geography*, one of the Hebrides, or Weſtern iſlands of Scotland, is ſituated off the coaſt of Inverneſs and Roſs-ſhires, from which it is ſeparated by the ſound of Skye, and a branch of the ſea called Lochalſh, while the Minch channel divides it from Long iſland. From the Point of Sleat in the ſouth-eaſt, to the Aird of Trotterniſh in the north-weſt, it extends 45 miles in length, but its breadth varies from 10 to 24 miles. The whole contents, meaſured carefully from Arrowſmith's map, are ſtated in the General Report of Scotland to amount to 535 ſquare miles, including 336,000 acres of land, and 10 ſquare miles of freſh-water lakes. From the numerous indentations of the ſea, no part of the land is farther diſtant from ſalt-water than four miles and a half.

The general aſpect of this iſland is extremely mountainous, ſo much ſo indeed, that not above twelve parts in a hundred of it are ſuſceptible of arable cultivation; and even theſe are diſpoſed in ſmall patches or ſtrips by the margin of the different bays, except at its north-weſterly extremity, where, for four miles, the land is flat, the ſoil fertile and well cultivated, and the farms incloſed and divided. But notwithſtanding this great proportion of mountain, Skye is far from being ſterile or barren. On the contrary, its hills, ſo widely extended, and towering ſo proudly to the ſkies, are in general of conſiderable value, from the excellent paſture with which they abound. This is particularly the caſe in the central and ſouthern diſtricts, where the hills of Cullin, reſting on a bed of limeſtone, produce very rich herbage, on which are fed a remnant of the ancient herds of deer, for which this iſland was formerly famed, and which continue ſtill to roam at large on theſe verdant heights. Moſt of the hills, in remote times, were clothed with wood; but except on the ſouth coaſt of Sleat, ſcarcely any foreſt-timber now remains in Skye. Here, however, are ſtill ſome good ſtools of natural wood, conſiſting of oak, aſh, elm, and birch, beſides alder and willow.

The crops cultivated in this iſland are beans, oats, potatoes, and ſome flax. Artificial graſſes and turnips are little known; but they are partially introduced, and it ſeems probable will ſoon become more extenſive, as they are ſo very eſſential to the welfare of cattle, which are the ſtaple land commodity of the iſland. In the gardens and "kail yards," moſt of the eſculent vegetables cultivated on the Mainland are raiſed with great ſucceſs, as are alſo the ſmaller fruits.

The live-ſtock of Skye is eſtimated at 4000 horſes, of a ſmall but hardy race; 18,000 head of cattle of an excellent breed, of which about 3800 are exported annually, forming the principal export of the iſland. The ſheep are computed at about 40,000 in number; but this computation is confeſſed by the reporter to the Board of Agriculture to be little more than conjecture. They conſiſt partly of the native yellow-faced kind, partly of Cheviots, and partly of the black-faced Lintons, which are the moſt eſteemed. Several thouſands of this uſeful animal are exported every year. Hogs, goats, and rabbits abound here, but they are all of them ſo wild, and ſo little under controul, as to afford no permanent ſource of revenue. Game of all kinds is abundant, but is thought to decline more and more, in proportion as the country is progreſſively cultivated. There are on the iſland two kinds of ſerpents or vipers, both of which are reckoned very venomous.

In the ſurrounding ſeas, which embrace 750 miles of coaſt, there are myriads of fiſh, particularly herring, mackarel, turbot, ſkate, ling, cod; and ſhell-fiſh, ſuch as oyſters, lobſters, &c.; ſo that combining the ſituation with other facilities, the inhabitants of Skye have an opportunity of enriching themſelves by the fiſheries, beyond any other iſlanders in Scotland, and in fact they apply themſelves to them with conſiderable induſtry, and frequently with great effect. Sometimes, however, they are miſerably tantalized with a profuſion of fiſh, when they cannot procure an ounce of ſalt to cure them, owing to the diſtance from the cuſtom-houſe, and to the complicated ſalt-duty regulations, which ſhut them up completely from either bettering their own circumſtances, or promoting the general proſperity of the nation by this otherwiſe abundant bounty of providence.

Kelp is made annually to the extent of 500 tons; and the manufacture of this article is capable of being greatly increaſed, to the no ſmall emolument of the natives, as well as to the increaſe of proprietors' rents.

The want of good roads has hitherto greatly retarded the internal proſperity of Skye, from the difficulty of conveyance, and this diſadvantage does not admit of being eaſily removed; not merely from the inequality of the ſurface, but from the circumſtance of its being ſo much cut up by brooks and rivulets, which, on every ſhower, ſwell into torrents that would require a great number of bridges.

The number of inhabitants in Skye, which, notwithſtanding continued emigration, is ſtill increaſing, was 17,775 in 1809, the time when the laſt cenſus was made; being at the rate of 33 to the ſquare mile, reckoning the whole iſland, or 275 to the ſame extent, limiting the eſtimate to the cultivated land only. It has been for many ages, and ſtill is, the property of the great clans, Macdonald, Macleod, and, till of late, Mackinnon. From the firſt of theſe has lately ſprung up the kindred clan of Macaliſter. The people, ingenious, ſhrewd, and active, are nearly all of the eſtabliſhed church of Scotland. Among them reſide a number of gentlemen, who have been in the army or navy, cadets of the chief families, whoſe manners have given a poliſh to thoſe of the inhabitants at large, which is obſervable in the behaviour even of the loweſt peaſant. In fact, every man in Skye ſeems to be a gentleman; whilſt the demeanour of the females exhibits an eaſe and an affability that no perſon could expect in a country ſo remote, and having ſo little communication with ſtrangers. Mr. Macdonald, in his Survey, juſtly obſerves, that "it is in truth a ſingular iſland, well deſerving the attention of the geologiſt and natural hiſtorian, and capable, by nature, of one day aſtoniſhing the patriot and political economiſt."

The General Report, &c. of Scotland, drawn up under the directions of ſir John Sinclair, bart. 8vo. 1814. Huſbandry of Scotland, by ſir John Sinclair, 8vo. 1815. Johnſon's Journey to the Weſtern Iſlands of Scotland, 8vo. 1775. Martin's Deſcription of the Weſtern Iſlands, 8vo. 1716. Account of the preſent State of the Hebrides, by James Anderſon, L.L.D. 8vo. 1787. Macdonald's Survey of the Hebrides, 8vo. 1807.

SKYRO. See SCIRO.

SKYTTE, JOHN, in *Biography*, was born at Nyköping in 1577. After being ſome time ſecretary in the Swediſh chancery, he was choſen by the ſtates to be preceptor to prince Guſtavus Adolphus, and at the ſame time by king Charles to ſuperintend the education of John, duke of Oſtrogothia, who was five years older than Guſtavus. It was, therefore, conſidered as a maſter-piece of policy in the king, that he placed the crown-prince and the pretender to the throne under the inſpection of ſo faithful and truſty an inſtructor. In 1622 he was made chancellor of the academy of Upſal, and in 1629 governor-general of Ingria, Livonia, and Carelia. He was held in high eſtimation by the learned of his time, and acquired great celebrity on account of his eloquence, and was employed either as envoy or ambaſſador to many foreign courts. Guſtavus Adolphus entertained for him the higheſt reſpect, and in 1624 the rank of baron was conferred on him. He was a great patron of literature, and rendered eſſential ſervice to the academy of Upſal, by founding a profeſſorſhip for the cultivation of the Latin language, literary criticiſm, and the political ſciences. As a politician, he was a determined enemy of the ariſtocracy, and laboured with great zeal to eſtabliſh royal authority. He died in 1645. Among his works was one, of which the following was the title; "Brief Inſtructions in regard to the Virtues and Arts which a Prince, who wiſhes to rule happily over his Kingdom and States, ought to exerciſe and employ; addreſſed to that exalted Lord and Prince Guſtavus Adolphus."

SKYTTE, BENEDICT, ſon of the preceding, was born in 1614, and ſtudied at Upſal. In 1629 he accompanied the Swediſh ambaſſador, general Spence, to England, where, on taking his leave, he was knighted by king Charles I. After this he continued his ſtudies at Dorpat, and travelled for his improvement, during which queen Chriſtiana gave him a place in her houſehold. He bore the marſhal's ſtaff at the diet in 1648, was appointed chancellor of the academy of Dorpat, and the year after was ſent to Denmark, to be queen Chriſtiana's proxy at the baptiſm of the princeſs Sophia Amelia, daughter of Frederic III. He enjoyed for ſeveral years the favour of his ſovereign, and in 1651, when the queen eſtabliſhed the order of the Amaranth, he was nominated one of the knights. Afterwards he fell into diſgrace, and was brought to trial, but he made ſuch an able defence that he was acquitted, and all the proceedings againſt him were annulled. He was reſtored to his ſeat as ſenator, and in 1665 was appointed governor of Eſthonia. He was employed on an important miſſion from king Charles Guſtavus to the duke of Courland, and he managed the buſineſs ſo well, that he received the approbation and cordial thanks of his ſovereign. In 1663 he was made ſupreme judge in Ingria, preſident of the tribunal of Wiſmar, and at the ſame time envoy in Germany. But his good fortune again deſerted him, he was diſmiſſed from his offices at the diet held in 1664, and declared incapable of ever being employed either at home or abroad. After this he retired to his eſtate, and ſpent his time in literary purſuits till his death, in 1683. He was a man of great learning, and made himſelf known by various works, among which were the following: "Diſſertatiuncula de Argumento quod Fœminæ Officium Legati mandari poſſit," 4to. "Oratio qua probatur Utilitatem pro Juſtitia, in Adminiſtratione Rerum publicarum colendam." Gen. Biog.

SLAA, in *Geography*. See SALLEE.

SLAB, an outſide ſappy plank or board ſawed off from the ſides of a timber-tree: the word is alſo uſed for a flat piece of marble.

SLABS *of Tin*, the leſſer maſſes which the workers at the tin-mines caſt the metal into: theſe are run into moulds made of ſtone.

SLAB-*Line*, in *Sea Language*, a ſmall cord paſſing up behind a ſhip's main-ſail or fore-ſail, and being reeved through a block attached to the lower part of the yard, is then tranſmitted in two branches to the foot of the ſail to which it is faſtened.

It is uſed to truſs up the ſail as occaſion requires, and more particularly for the convenience of the pilot or ſteerſman,

man, that they may look forward beneath it as the ſhip advances. Falconer.

SLABBERING-Bit, in the *Manege.* See Mastigadour.

SLABETZ, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 7 miles S. of Rakonitz.

SLABODA, a town of Poland, in the palatinate of Braclaw; 40 miles N.W. of Braclaw.

SLAB-TOWN, a village of America, in Burlington county, New Jerſey, about half-way between Burlington and Mount Holly, and about four or five miles from each.

SLACK, in *Agriculture*, provincially a valley or ſmall ſhallow dale or dip.

Slack *a Leg*, in the *Manege*, called in French *mollir la jambe*, is ſaid of a horſe when he trips or ſtumbles.

Slack *the Hand*, is to ſlack the bridle, or give a horſe head.

SLACK-CLOTH, in *Sail-Making*, a certain quantity of cloth allowed to be gradually gathered up, in ſewing on the bolt-rope to the ſail, more than the length of the bolt-rope; otherwiſe the rope, by ſtretching in the wearing, might occaſion the ſail to ſplit.

SLACKEN, in *Metallurgy*, a term uſed by the miners to expreſs a ſpongy and ſemivitrified ſubſtance, which they uſe to mix with the ores of metals, to prevent their fuſion. It is the ſcoria, or ſcum, ſeparated from the ſurface of the former fuſions of metals. To this they frequently add a lime-ſtone, and ſometimes a kind of coarſe iron-ore, in the running of the poorer gold-ores.

SLACK-WATER, in *Sea Language*, denotes the interval between the flux and reflux of the tide, or between the laſt of the ebb and the firſt of the flood, during which the current is interrupted, and the water apparently remains in a ſtate of reſt.

SLADE, in *Agriculture*, a term provincially ſignifying a ſledge. See Sledge.

Slade, *Down*, a provincial term ſignifying to draw back part of the mould into the interfurrow with the plough dragging or ſlading upon its ſide.

Slade *Point*, in *Geography*, a cape on the N.E. coaſt of New Holland; 15 miles S.E. of Cape Hillſborough.

SLAG, in *Metallurgy*, &c. denotes vitrified cinder. See Smelting.

Slag is found an uſeful material in repairing the roads in many places.

SLAGE, Slagen, or *Schlagen*, in *Geography*. See Schlawa.

SLAGELSE, a town of Denmark, in the iſland of Zealand; 42 miles W.S.W. of Copenhagen. N. lat. 55° 26′. E. long. 11° 29′.

SLAIGHTWAITE, a townſhip and chapelry in the pariſh of Huddersfield, in Aylrig wapentake, and Weſt Riding of the county of York, England, is four miles from the town of Huddersfield, and 190 from London. According to the population reports of 1811, this townſhip contained 425 houſes and 2277 inhabitants, the greater part of whom are engaged in the manufacture of cotton goods, which is the ſtaple trade of this diſtrict.

SLAKE, in *Agriculture*, a term ſignifying the ſaturating of quick-lime with moiſture, as water, &c.

SLAKED Lime, ſuch as is reduced into a powdery ſtate by the action of water upon it, or the hydrate of lime. In this caſe, the lime is combined with about one-third of its weight of water, that is, about 55 parts of the former abſorb or drink up about 17 parts of the latter. See Lime.

SLAM, the refuſe of alum-works, which is uſed as a manure with ſea-weed and lime, in Yorkſhire.

SLAMMERSDORP, in *Geography*, a town of the duchy of Holſtein; 7 miles N.E. of Segeborg.

SLANDER, in *Law*. See Scandalum *Magnatum*.

SLANE, in *Geography*, a poſt-town of the county of Meath, Ireland, ſituated on the river Boyne. In the time of Hugh de Lacy this was a town of ſome note, being one of the boroughs in his palatinate of Meath. Here were many religious buildings, one of which was ſometimes uſed as the reſidence of a royal prince, and was rebuilt by the lord of Slane in 1512. In the preſent remains of lord Slane's building, there are, according to Mr. Archdale, ſeveral fragments of the ancient abbey, and many of the architraves were evidently cut out of the ornamental parts, particularly one with the appearance of a head crowned. The caſtle that belonged to the lords of Slane, and was forfeited by them in 1641, is now the property of the Conyngham family. It has been much beautified, and is an elegant reſidence. At New Grange, near Slane, is a moſt remarkable mount, barrow, or rath, with a curious chamber in the centre, conſtructed of rude ſtones, and acceſſible only by a long paſſage, low, and very narrow. Governor Pownall has given a minute deſcription of this barrow in the Archæologia, &c. It is alſo deſcribed in the "Collectanea de Rebus Hibernicis." Slane is 24 miles N. by W. from Dublin.

SLANETZ, a river of Ruſſia, which runs into the Tobol; 60 miles S. of Tobolſk.

SLANEY, a river of Ireland, riſing in the Wicklow mountains, near the ſource of the Liffey, and flowing in a ſouthern direction through the counties of Wicklow, Carlow, and Wexford, to the harbour of Wexford. The towns of Stratford on Slaney, Baltinglaſs, Rathvilly, Tullow, Newtown Barry, Enniſcorthy, and Wexford, are ſituated on it, and it receives the waters of the Derry, Bann, Urrie, and ſeveral ſmaller ſtreams. It is navigable for ſmall ſloops to Enniſcorthy.

SLANGE, Nicholas, in *Biography*, a Dutch hiſtorian of conſiderable celebrity, was born at Slagelſe in the year 1657, of which place his father was the miniſter, and he was afterwards biſhop of Viborg. Nicholas travelled at an early period, and in 1679 he paid a viſit to Oxford, and in the year following he went to Cambridge. On his return he became, in 1681, ſecretary to the Daniſh chancery, and after going through various gradations of rank and office, he was ennobled in the year 1731. He died in 1737. He wrote "A Hiſtory of Chriſtian IV." which was publiſhed at Copenhagen in 1749, in two volumes, folio. It was afterwards tranſlated into the German language. Gen. Biog.

SLANGER, in *Geography*. See Tumb.

SLANGERUP, a town of Denmark, in Zealand; 16 miles N.W. of Copenhagen. N. lat. 45° 51′. E. long. 12° 10′.

SLANT, in *Commerce*, a copper coin of Sweden. Here are ſingle and double ſlants, at 1 and 2 ore ſilver, or 3 and 6 ore kopper; and rundſtycken, of 1 ore kopper; and alſo half rundſtycken: 96 double ſlants, 192 ſingle ſlants, or 576 rundſtycken, are to paſs for 1 ſpecie rikſdaler: and this, commonly called the Swediſh dollar, is worth 4*s.* 7½*d.* ſterling.

SLAPANITZ, in *Geography*, a town of Moravia, in the circle of Brunn; 5 miles E.S.E. of Brunn.

SLAPDASH, in *Rural Economy*, provincially rough caſt, or the liquid external coating of buildings.

SLAPER's Bay, in *Geography*, a bay on the W. coaſt of Africa; 10 miles E. of Cape Blanco.

SLARADIA, a town of Aſiatic Turkey, in Natolia; 28 miles N.N.W. of Eſkir-Shehr.

SLASHER, in *Rural Economy*, a term ſometimes applied to a plaſher of hedges.

SLATCH, at *Sea*. When a rope or cable hangs ſlack, the ſeamen call the middle part, which hangs down, *the ſlatch of the cable*, or rope: ſo alſo, after long foul weather, if there come a ſmall interval of fair, they ſay, *this is a ſlatch of fair weather*. But the term is generally applied to the period of a tranſitory breeze of wind.

SLATE, *Argillaceous Schiſtus* and *Argillite* of Kirwan; *Clay-ſlate*, Jameſon; *Thonſchiefer*, Werner; *Schiſte Argileux*, Fr.; in *Mineralogy* and *Geology*, one of the great rock-formations compoſing the cruſt of the globe, of which roof-ſlate is a well-known variety. The ſlaty or ſchiſtoſe ſtructure is common to numerous rocks, which differ from each other, both in their geological poſition and conſtituent parts; hence we have a great variety of ſlate-rocks, amongſt rocks which have been denominated primary, tranſition, and ſecondary. (See Rocks.) The term ſlate appears to have a more appropriate meaning, when reſtricted to thoſe rocks which, in their compoſition and ſtructure, are moſt nearly allied to roof-ſlate or the clay-ſlate of Werner.

The moſt common colours of ſlate are a yellowiſh-grey, a greeniſh-grey, or a dark-blue or purple-grey: ſome varieties incline to a red, and others to a black-grey. Slate of the moſt perfect kind has a gliſtening luſtre. It paſſes by gradation into mica-ſlate in the rocks called primary; and in rocks conſidered as ſecondary, it paſſes into ſlate-clay or ſhale.

The ſtructure of ſlate-rocks *en maſſe* is tabular, the ſmall ſtructure laminar, the cleavage of the laminæ being parallel with the tables; hence ſlate has been repreſented by ſome geologiſts as moſt diſtinctly ſtratified; and the ſlaty cleavage is ſaid to be always parallel with the ſtrata; but this we believe to be a miſtake, ariſing from confounding the diviſions or joints of the tabular maſſes with the inclination of the beds. In the ſlate-quarries of Weſtmoreland and Cumberland, we have invariably obſerved the tables or diviſions of the ſlate riſe at a more elevated angle than the bed of which they form a part; and they are ſometimes perpendicular, when the true dip of the bed is not more than forty degrees.

The ſlaty ſtructure of the ſtone is the reſult of a proceſs analogous to cryſtallization, by which the ſlate is divided into rhomboidal blocks or tables: between the bottom of one block and the top of another, there is frequently a ſeam of clay, which forms, what the workmen call, the foot of the ſlate. The ſlate will divide to this ſeam in a direction nearly at right angles with it; and ſometimes between the upper and the lower block, there will be a thin horizontal ſtratum of ſlate occupying the place of the clay. This proves that the ſlate is not formed by mechanical ſtratification, and that the elevation of the tabular maſſes is unconnected with the elevation of the rock itſelf.

Slate-rocks vary in hardneſs, but they yield to the knife. They conſiſt of an intimate intermixture, in various proportions, of ſiliceous earth, alumine, and iron; and ſometimes contain a portion of lime, magneſia, manganeſe, and bitumen. Slate forms entire mountains, and mountain chains, and ſometimes diſtinct beds, alternating with other rocks. It moſt frequently reſts upon granite, gneiſs, or mica-ſlate.

Slate-rocks are frequently interſected by veins of quartz, and by metallic veins of lead, cobalt, and ſilver: it alſo contains beds of copper pyrites, red copper-ore, copper-green, malachite, iron pyrites, magnetic pyrites, glance cobalt, grey cobalt-ore, arſenical pyrites, blende and galena. The tin-veins in Cornwall ſometimes paſs through the killas, which is a variety of ſlate-rock.

Various rocks frequently occur imbedded in ſlate, particularly whet-ſlate, or hone, chlorite-ſlate, talcous-ſlate, drawing-ſlate, and alum-ſlate. Beds of flinty ſlate occur in this rock, and alternate with as well as graduate into it. Flinty ſlate appears to be ſlate in which a large proportion of ſiliceous earth is combined, until it approaches nearly to the nature of chert or flint. Organic remains are occaſionally found in ſlate, on which account it is not conſidered by many geologiſts as a primary rock, if indeed there be any to which that term is appropriate. The ſlate which contains organic remains has been called by the Germans *the newer clay-ſlate*, and *tranſition-ſlate*; but remains of vegetables have been diſcovered in the ſlate of the Higher Alps in the vicinity of Mont Blanc, which may be ſuppoſed to have a better claim to the rank of primary than any other ſlate-rocks in Europe.

In a very large proportion of ſlate-rocks, the baſis of the ſlate is intermixed with particles or fragments of other rocks; and when theſe are ſufficiently large to be diſcerned without a lens, this kind of rock has received from the Germans the name of *grauwacke ſlate*. It is generally incumbent on the rocks denominated primary, and is ſuppoſed to be of more recent origin than the finer ſlate; but late obſervations have ſhewn that grauwacke is ſometimes covered with granite and mica-ſlate. The killas of Cornwall appears, in many ſituations, to approach the nature of mica-ſlate, having a ſhining luſtre, and a light grey colour, as if compoſed of an intimate intermixture of clay-ſlate with mica-ſlate. In Cornwall and Devonſhire it occupies, in general, the ſame relative poſition with granite, in which mica-ſlate frequently occurs in other diſtricts reſting immediately upon it. The metallic veins which interſect theſe rocks are principally filled with ores of tin and copper, imbedded in a matrix of quartz; but it is obſerved, that the contents of the vein frequently vary as it paſſes through different rocks: if it contain tin-ore in the granite, it will change to copper-ores in the killas; and if tin be moſt abundant in the killas, the vein will change its contents as it paſſes into the granite. Veins of granite are alſo obſerved to ſhoot up into the killas, which is a proof that this kind of ſlate-rock is at leaſt as ancient as the granite. This fact has given riſe to ſome controverſy among geologiſts, the diſciples of Werner contending that the granite in the ſlate or killas was not in veins, but formed ridges or inequalities riſing above the ſurface, which had been incloſed by ſubſequent depoſitions of the ſlate. For this explanation there can be no better reaſon given than its convenience in ſuiting a particular hypotheſis reſpecting the formation of theſe rocks. Among other facts, which might be cited to prove that the granite veins penetrate the ſlate, there is one deſcribed in the "Annals of Philoſophy," May 1814, which appears deciſive. It occurs in Touſchole, in Cornwall. "The ſlate or killas is of a greyiſh dark colour, rather hard, but breaks into large fragments in the direction of the ſtrata. The granite is of a fine grain, and the felſpar is of a light fleſh-colour, and contains but a ſmall portion of mica. At the junction, numerous veins of granite may be traced from the rock of granite into the ſlate. Some of theſe veins may be obſerved upwards of fifty yards, till they are loſt in the ſea; and in point of ſize, vary from a foot and a half to leſs than an inch.

It may deſerve notice, that as the felſpar is of a fleſh-red colour, it is impoſſible for any obſerver to conſider them as quartz veins. One of theſe large veins is diſlocated, and heaved ſeveral yards by a croſs courſe. Another of theſe veins of granite, after proceeding vertically ſome diſtance, ſuddenly forms an angle, and continues in a direction nearly horizontal for ſeveral feet, with ſchiſtus, or ſlate, both above and below it. This appearance moſt completely deſtroys one of the theories ſuggeſted for the explanation of ſimilar veins at St. Michael's Mount; *viz.* that a ridge of projecting granite had been left, and ſlate depoſited afterwards on its ſides." It is, indeed, quite impoſſible to conceive that a narrow vein of granite ſhould ſhoot up into empty ſpace for a conſiderable diſtance, and then aſſume a zig-zag direction, unſupported by any ſolid ſubſtance on the ſides. The ſlate-rock muſt have exiſted when the vein was formed, and from its reſiſtance have given it the form above deſcribed. Slate is one of the moſt abundant rocks in alpine diſtricts, though that variety which ſplits into thin durable laminæ, forming good roof-ſlate, is far from being ſo common. The localities of common ſlate are ſo numerous in mountainous diſtricts, that it were uſeleſs to point them out. Roof-ſlate, the *ſchiſte ardoiſe* of the French, is found on the weſtern ſide of our iſland in the counties of Cornwall and Devon, in various parts of North Wales and Angleſea, on the north-weſt parts of Yorkſhire, near Ingleton, and in Swaledale, alſo in the counties of Cumberland and Weſtmoreland. It occurs in a low range of mountains at Chamwood foreſt, in Leiceſterſhire, near the centre of England. Several geologiſts have ſtated that ſlate is found in Derbyſhire, which is a miſtake, as no rock ſimilar to clay-ſlate or roof-ſlate occurs in that county. The inhabitants of that part of England make uſe of a micaceous ſand-ſtone for roofing, which they denominate ſlate. This ſtone is found in ſtrata among the other ſtrata accompanying coal. Of the quality of the different kinds of Engliſh roof-ſlate, we ſhall offer ſome obſervations at the concluſion of this article. Slate abounds in various parts of Scotland, and in the county of Wicklow, and other mountainous parts of Ireland. France poſſeſſes many valuable beds of roof-ſlate, near Laferriere in Normandy, and in the neighbourhood of Angers. The laſt is the moſt important, as furniſhing ſlate of the moſt perfect quality, and its extent and prodigious thickneſs make it regarded as inexhauſtible. It is further remarkable on account of the very ſingular and intereſting organic remains that occur between ſome of the laminæ of ſlate. It is, perhaps, one of the moſt valuable repoſitories of ſlate at preſent known.

This bed extends for a ſpace of two leagues, paſſing under the town of Angers, which is built, as well as covered, with the ſlate; thoſe blocks being employed in maſonry which are the leaſt diviſible. The quarries which are actually explored, are all in the ſame line from weſt to eaſt, as well as the ancient pits, the bed of the beſt roof-ſlate riſing to the ſurface in this direction. Immediately under the vegetable earth is found a brittle kind of ſlate, which, for four or five feet deep, ſplits into rhomboidal fragments.

A little lower is what is called the building-ſtone, which is a firm ſlate, but ſcarcely diviſible. This is employed in the conſtruction of houſes, after it has been ſufficiently hardened by expoſure to the air. At fourteen or fifteen feet from the ſurface is found the good ſlate, which has been quarried to the perpendicular depth of about three hundred feet; the remaining thickneſs being unknown.

As to the interior ſtructure of this great maſs of ſlate, it is divided by many veins or ſeams of calcareous ſpar and quartz, about two feet thick, by fifteen or ſixteen in height: theſe veins are parallel, and proceed regularly from weſt to eaſt, in a poſition riſing ſeventy degrees to the ſouth; they are interſected by other veins at intervals of a ſimilar kind, but whoſe riſe is ſeventy degrees north; ſo that when they meet the former, they either form rhombs, or half rhombs, which have been compared to the letter V, ſome being upright, and others reverſed.

All the layers, or laminæ, of the ſlate, have a direction ſimilar to thoſe of the veins of quartz, which riſe ſouth ſeventy degrees; and when interſected by veins that have an oppoſite inclination, the direction of the ſlaty laminæ is not changed. The whole maſs is thus divided into immenſe rhomboids, compoſed of plates all parallel among themſelves, and with two of the faces of the rhomboid.

The ſlate of Angers is extracted in blocks of a fixed ſize, which are divided into leaves for roofing-ſlate. It is betwixt theſe leaves that there are frequently found veſtiges of marine animals, and particularly pyritous impreſſions of *pous de mer* (the ſea-louſe, a ſmall univalve ſhell), alſo of ſmall cheviettes (ſhrimps or prawns), and a ſpecies of crab, of which the body is about a foot in breadth, and fourteen or fifteen inches in length, the tail having nine or ten rings. The ſhrimps are ſometimes ſo numerous, that forty have been counted on a ſlate of a foot ſquare.

None of the above animals reſemble any known exiſting ſpecies. But the moſt remarkable circumſtance in theſe impreſſions, particularly in the large crabs, is, that though there be no ſign of the body having been cruſhed, yet it can ſcarcely be ſaid to have any thickneſs whatever. They rather reſemble engravings than figures in relievo, the convexity of theſe crabs above a thin leaf of ſlate not riſing more than the fourth, and ſometimes not more than the tenth part of a line; nor is it perceivable that the body of theſe crabs penetrates into the leaves of ſlate. What adds to the ſurpriſe, is the nearly vertical poſition in which theſe impreſſions are found in the mine.

A ſeries of theſe leaves of ſlate may be compared to a ſet of books placed upon ſhelves; and the impreſſions of crabs, and other marine animals, to engraved plates in the volumes: they do not, in fact, occupy more thickneſs. It is equally difficult to conceive how the bodies of theſe animals, though perfectly defined, could be reduced to a ſimple ſurface, without thickneſs. Theſe ſlates alſo preſent beautiful dendritical pyrites, more than a foot in extent. The pyrites are ſometimes in ſmall grains, diſſeminated, like duſt, upon the ſurface of the ſlates, where may alſo be obſerved many little ſtars of ſelenite.

When the blocks of ſlate have been drawn from the quarry, if they are left expoſed to the ſun, or the open air, for ſome days, they loſe what is called the *quarry-water*, and then become hard and untractable, and can only be employed as building ſtone. Froſt produces a ſingular effect on theſe blocks: while frozen they may be broken with more eaſe than before; but if thawed rather quickly, they are no longer diviſible: yet this quality may be reſtored by expoſing them once more to the froſt; but if the operation be often repeated, it becomes impoſſible to reduce them to leaves.

Some ſmaller beds of ſlate are worked on the northern declivities of the Pyrenées; but we have no account of any ſlate-quarries on the ſouthern ſide, or in any part of Spain: yet it can ſcarcely be doubted that this rock exiſts in ſome of the mountainous parts of that kingdom.

Only one quarry of ſlate is ſaid to be opened in Italy; it is at Lavagna, in the ſtate of Genoa, and furniſhes ſlate of an excellent quality, and ſo impervious, that it ſerves to line the ciſterns in which olive oil is preſerved. The canton of Glaris, in Switzerland, is the only one in which roof-ſlate is procured. Roof-ſlate occurs in Saxony, and in various mountainous diſtricts in the north of Europe; it is found alſo on the continent of North America; and as it is only a modification of clay-ſlate, which is an abundant rock, it is probable that its localities are much more numerous than are at preſent known in alpine diſtricts in every part of the globe.

As this ſubſtance forms the moſt light, elegant, and durable covering for houſes, and is, of courſe, of conſiderable value; it is rather ſurpriſing that ſo much indifference prevails reſpecting the ſearch for it, in thoſe diſtricts where common ſlate, or *clay-ſlate*, abounds. We believe all the roof-ſlate quarries at preſent worked are thoſe which accident has diſcovered. This neglect is the more remarkable, when we conſider the great expence frequently incurred in ſearching for coal, a ſubſtance of much leſs value in proportion to the weight.

All the beſt beds of roof-ſlate with which we are acquainted, improve as they ſink deeper into the earth; and few, if any, are of a good quality near the ſurface, or are indeed ſuitable for the purpoſe of roofing. There cannot be a doubt that many beds of ſlate, which appear ſhattered and unfit for architectural uſe, would be found of a good quality a few yards under the ſurface; for the beſt ſlate, in many quarries, loſes its property of ſplitting into thin laminæ by expoſure to the air. Notwithſtanding the value of ſlate, few quarries are worked to a very great depth, or have ſubterranean galleries, like mines. The quarry or ſlate-mine at Rimagne, four leagues to the weſt of Charleville, on the Meuſe, in France, is an exception. The mouth of the mine is near the ſummit of a hill: the bed inclines forty degrees to the horizon: it is about ſixty feet in thickneſs, but its extent and depth are unknown. It has been purſued, by a principal gallery, to the depth of 400 feet; and they have driven many lateral galleries, which extend about 200 feet on the ſide of the main gallery, where 26 ladders are placed in ſucceſſion, for the paſſage of the workmen and the carriage of the ſlate. In this bed, which is 60 feet in thickneſs, there are only forty feet of good ſlate, the other being mixed with quartz. They cut the ſlate into blocks of about 200lbs., which they call *faix*: every workman, in his turn, carries them on his back to the very mouth of the pit, mounting the 26 ladders, or a part of them, according to the depth of the bed where he is working. When brought to day, theſe blocks are firſt ſplit into thick tables, which are called *repartons*. The workman holds the block between his legs, puts a chiſſel on the ſide, and divides it with a blow of a mallet. The *repartons* are divided in a ſimilar manner into roof-ſlates. Theſe operations muſt be performed ſoon after the blocks are drawn from the quarry; for if the ſtone has time to dry, it would no longer be poſſible to ſplit it. Some of the ſlate-galleries paſs under the river Meuſe.

There are few places in Great Britain where ſlate is worked as a mine under ground; moſt of the quarries are open to the day; and the covering of other rocks, or of coarſe ſlate, which requires removing, greatly increaſes the expence. There is one ſlate-quarry worked as a mine by penetrating the interior of the mountain at Place-Fell, on the head of the lake of Ullſwater, in Cumberland. Slate is alſo worked under ground on the weſtern ſide of Yorkſhire, adjoining Weſtmoreland. In many other ſituations it is probable that ſlate might be worked to advantage, in ſubterranean galleries, ſimilar to thoſe deſcribed in the quarries at Charleville; for as this mineral is generally of a better quality at a conſiderable depth, the expence of procuring it by mining would be much leſs than that of removing the load of upper rocks, and working it in open quarries, as at preſent; at leaſt the moſt valuable ſlate might be purſued to a far greater depth than is practicable in the common method in open quarries.

Slate, to be of a good quality for roofing, ſhould have the property of ſplitting into thin even laminæ: it ſhould reſiſt the abſorption of water; to prove which, it ſhould be kept ſome time immerſed in water, being weighed before and after the immerſion, wiping the ſurface dry; it is obvious, that the ſlate which gains the leaſt weight by this proceſs is the leaſt abſorbent. It ſhould reſiſt the proceſs of natural decompoſition by air and moiſture: this depends on its chemical compoſition and compactneſs, and is ſhewn by its reſiſting the proceſs of vegetation. That ſlate which is the moſt liable to decay, will be the ſooneſt covered with lichens and moſſes. The ſlate from Charnwood foreſt, in Leiceſterſhire, reſembles, in colour and appearance, the Weſtmoreland ſlate, but it will not ſplit ſo thin, nor would this be deſirable, for the vegetation which takes place upon it requires the roofs to be frequently ſcraped; this carries away a portion of the ſurface: a ſecond growth of moſſes produces a further wearing of the ſlate: hence a ſlate of a certain thickneſs from this part of England is not ſo durable as that from North Wales, Cornwall, or Weſtmoreland. This decay is probably owing to the greater quantity of alumine in its compoſition; it does not contain pyrites, nor have any organic remains been diſcovered in it.

Few ſlate-rocks have been accurately analyſed; a reddiſh-purple ſlate from North Wales contained, according to Kirwan, .38 ſilex, .26 alumine, .8 magneſia, .4 lime, and .14 parts iron; but as there is in this analyſis a loſs of 10 *per cent.*, it cannot be conſidered as very accurate. As the hardneſs of ſlate ariſes principally from the ſilex it contains, which is of all the earths the leaſt favourable to vegetation, thoſe ſlates which are the hardeſt when firſt taken from the quarry, and which have the leaſt ſpecific gravity, are to be preferred; for the increaſe of weight in ſlates is owing to the preſence of iron, either in pyrites, or a ſtate of oxyd. To the preſence of iron, many kinds of ſtone and ſlate alſo owe their tendency to decompoſition. The pyrites being decompoſed by moiſture, and the iron admitting a ſtill higher degree of oxygenation, the ſurface of the ſtone ſwells and peels off, or falls into an ochrey powder.

According to Dr. Watſon, (biſhop of Landaff,) the ſpecific gravity of the Weſtmoreland ſlate varies in different quarries, from 2797 to 2732 ounces the cubic foot. The effect of froſt is very ſenſible on tiled houſes, but is ſcarcely felt on ſlated houſes; for good ſlate imbibes very little water. According to an experiment made by Dr. Watſon on Weſtmoreland ſlate, compared with tile, in which two pieces of each, about 30 inches ſquare, were immerſed in water 10 minutes, and then taken out and weighed as ſoon as they ceaſed to drop; the tile had imbibed about $\frac{1}{7}$th of its weight of water, and the ſlate had not abſorbed the $\frac{2}{100}$th part of its weight: indeed the wetting of the ſlate was merely ſuperficial. When placed before the fire, in a quarter of an hour the ſlate was of the ſame weight as it had been before it was put into the water; but the tile had only loſt about 12 grains of its moiſture, which was as near as could be expected to the quantity which had been ſpread over its ſurface; for it was the amount gained by the ſlate, the ſurface of which was equal to that of the tile. The tile was left to dry ſix days, in a room heated to ſixty degrees, but did not loſe all the water it had imbibed till the end of that time.

The ſlate in Weſtmoreland is blaſted from the quarry in large maſſes, and ſplit with proper tools by the workmen. Though the ſpecific gravity of Weſtmoreland ſlate from different quarries is nearly the ſame, yet all the ſorts are not capable of being ſplit into an equal degree of thinneſs. Here alſo the quality varies with the depth of the quarry, that being the beſt which is raiſed from the greateſt depth.

The grey-blue ſlate from Donyball, in Cornwall, weighs only 2512 ounces to the cubic foot, which is conſiderably lighter than that of Weſtmoreland. This ſlate is generally preferred to any other for its lightneſs, and enduring the weather; but Dr. Watſon is of opinion, that in durability it does not excel that of Weſtmoreland. The Donyball ſlate is ſplit into laminæ about one-eighth of an inch thick when it is applied to the covering of a roof; it then weighs rather more than 26 ounces to the ſquare foot. The pale blue ſlate from Ambleſide, in Weſtmoreland, weighs about two ounces more in the ſquare foot than the former. In many inſtances, we believe ſlate of a thinner kind is uſed in ſeveral modern buildings to ſave the expence of timber in the roof, where cheapneſs rather than durability is a principal object with the architect. According to an eſtimate of Dr. Watſon, the relative weights of a covering of the following different materials, for forty-two ſquare yards of roof, are as under:

	Cwt.
Copper - - -	4
Fine ſlate - - -	26
Lead - - - -	27
Coarſe ſlate - - -	36
Tile - - - -	54

A ton of fine ſlate will cover a larger ſurface than a ton of lead; and where there is water-carriage, does not coſt one-fourth of the price. Slate might, therefore, be uſed generally inſtead of lead, with great advantage. Watſon's Chemical Eſſays, vol. iv.

The moſt extenſive ſlate-quarries in Great Britain are the property of lord Penryn, near Bangor, in Caernarvonſhire. There is a rail-road formed from the quarries to the ſea for the conveyance of the ſlate, which is of an excellent quality, and is ſent to various parts of the world. The moſt remarkable ſituation where ſlate is procured in Cumberland, or perhaps in Great Britain, is Hourlton cragg, a lofty mountain near the lake of Buttermere, about 2000 feet above the level of the lake, and nearly perpendicular. On account of the difficulty of acceſs, the workmen take their proviſions for the week, and ſleep in temporary huts on the ſummit. During the winter months they are generally involved in clouds, and not unfrequently blocked up by the ſnow. The ſlate is conveyed down a zigzag path cut in the rock on ſledges, one man attending to prevent the acceleration of the deſcent. When the ſlate is emptied at the bottom, the ſledge is carried back on his ſhoulders to the ſummit.

There are conſiderable ſlate-quarries near Ulverſtone, in Lancaſhire. A coarſe ſlate is got near Ingleton, in Yorkſhire, and alſo in the vicinity of Settle in that county. The Ingleton ſlate frequently contains cubical pyrites, and is ſometimes covered with dendritical pyrites.

Alum-ſlate, *ampellite* of Haüy, is ſometimes imbedded in clay-ſlate, but more frequently in ſtratified ſecondary rocks, and is not eſſentially different from ſome of the coal-ſhales. (See ALUM.) The alum-ſlate, or alum-ſhale of Whitby, is of vaſt and unknown thickneſs, forming the baſe of the Cleveland Hills in the North Riding of Yorkſhire, extending about thirty miles eaſt and weſt from Robinhood's bay, to Ginſborough, Stokeſly, and Oſmotherly. On the ſouth ſide of the Cleveland Hills the alum-ſlate is principally covered by ſand-ſtone and marle. On the north-eaſt, the alum-rock extends along the coaſt, about thirty miles from Robinhood's bay to Huntcliff. The height of the alum-cliffs, which are perpendicular from the ſea, varies from 100 to 140 yards. Whitby abbey ſtands near an awful precipice of alum-ſlate or rock, which is undermined by every returning tide. At low water the alum-rock may be ſeen extending far to the eaſt, forming a flat pavement, on which the obſerver may walk ſecure, treading at almoſt every ſtep on the organic remains of the inhabitants of a former world, which are abundantly diſſeminated through the whole maſs beneath, and projecting from the ſides of the black and frowning cliffs above. The alum-ſlate has been perforated near the ſea to the depth of 130 yards, without diſcovering the ſubjacent rock, to which we may add the height of the cliffs above, which will make a total thickneſs exceeding 220 yards. The upper parts of the bed are found more productive of alum than the lower. From the quantity of pyrites contained in this rock, it ſometimes takes fire ſpontaneouſly, when a heap of it which has fallen from the cliffs becomes moiſtened with ſea-water.

The animal remains are ſcattered through every part of the rock. They conſiſt principally of numerous ammonites, nautilites, belemnites, foſſile vertebræ (ſuppoſed to belong to the ſhark), with bivalve ſhells, foſſile wood, and jet. Mr. Bakewell conſiders the alum-ſhale or ſlate, and the ſtrata which cover it, as a peculiar local formation ſubjacent to the roe-ſtone, but above the coal-formation of Yorkſhire or Durham. The alum-ſlate is in fact a thin bed of indurated pyritous ſlate-clay, differing little, except in geological poſition and its organic remains, from ſome of the coal-ſhales.

The alum-ſlate of Whitby has a very dark grey colour, a ſlaty ſtructure, and rather a ſilky luſtre; it ſplits, by expoſure to the atmoſphere, into very thin laminæ; it varies in hardneſs, but is all ſofter than roof-ſlate. The particular advantage which the country near Whitby poſſeſſes for the manufacture of alum, is derived from the alum-ſlate riſing in precipitous cliffs, which afford facilities for working and burning the ſtone. Though many of the coal-ſhales might yield an equal quantity of alum, the difficulty of raiſing them to the ſurface would in moſt ſituations be too great to repay the expence. The alum-ſlate is piled in vaſt heaps and ſet fire to; a ſlow combuſtion is continued for ſeveral months, by the inflammable matter combined with the ſtone. The ſaline contents are extracted by ſolution, a ſmall quantity of potaſh is added, and the alum is cryſtallized by evaporation. (Bakewell's Introduction to Geology.) From the alum-rock of Yorkſhire, nearly all the alum of commerce in England is produced.

According to the analyſis of Klaproth, alum-ſlate contains

Sulphur - - - - -	0.28
Carbon - - - - -	1.96
Alumine - - - - -	1.60
Silex - - - - - -	4.00
Black oxyd of iron - - -	64
Sulphate of iron, lime, and potaſh, each	15
Water - - - - - -	70

M. Klaproth remarks, that the ſulphur in the alum-ſlate which he analyſed was not united to the iron but to the carbon, in a manner at preſent unknown. In the alum-ſlate of Whitby, we believe the ſulphur is combined both with the iron and carbon.

Drawing-ſlate frequently accompanies alum-ſlate; it is much ſofter than common ſlate, and contains, like alum-ſlate, a conſiderable portion of carbon: its colour is a greyiſh-black: it is known by the property which it poſſeſſes of leaving a dark line when rubbed on paper. It is ſoft, and ſometimes rather unctuous: ſome varieties have a ſmall degree of luſtre. The fracture, in ſmall fragments, is ſcarcely ſlaty, and ſometimes approaches the conchoidal. Drawing-ſlate is eaſily cut with the knife. Under the blowpipe it turns white or yellow. It ſometimes effloreſces like alum-ſlate. According to Wiegleb, it contains

Silex	64
Alumine	21.25
Carbon	11
Oxyd of iron	2.75
Water	7.50

Drawing-ſlate is employed by maſons, carpenters, &c. to mark with. When fine and pure, it is uſed by artiſts for deſigns. In France it is called *pierre d'Italie*, in England, *French chalk.* It is found in France, near Séer, in the department of l'Orne, and in the environs of Cherbourgh. It is found alſo in Spain and Italy.

Whet-ſlate, or hone, the *novaculite* of Kirwan, occurs imbedded in clay-ſlate: its moſt common colour is greeniſh-grey, inclining to yellow: it is much harder than common ſlate: its texture is fine-grained, nearly compact, and the fracture of the ſmall pieces ſplintery or conchoidal, reſembling flinty ſlate. Its ſpecific gravity is about 2.72. Whet-ſlate is tranſlucent on the edges; it does not efferveſce with acids, and it melts into a brown enamel under the blowpipe. From its green colour, and rather greaſy feel, it may be conſidered as intermediate between hard talcous-ſlate and clay-ſlate. Though it yields to the point of a knife, or even of a copper tool, it acts upon the flattened or round ſurfaces of metals, and is uſed for ſharpening and poliſhing the finer kinds of cutlery. It is of conſiderable value on account of this property, and was firſt brought from the Levant. We have no whet-ſlate of a fine quality in England. An inferior kind is procured from Chamwood foreſt, in Leiceſterſhire. It exiſts of a finer quality in the promontory of Howth, near Dublin. The common whet-ſlate of commerce is procured from Saxony.

SLATE-*Spar, Schiefer-ſpath*, Werner, occurs in lime-ſtone beds, in mountains called primitive. Its colour is milk-white, or greeniſh and reddiſh-white, its luſtre ſhining and pearly. Slate-ſpar is tranſlucent and ſoft, its ſtructure coarſely lamellar, paſſing into ſlaty, and ſometimes curved or undulating: it is infuſible, and efferveſces with violence in acids.

SLATE, in *Rural Economy*, a well-known, neat, convenient, and durable material, for the covering of the roofs of buildings. There are great varieties of this ſubſtance; and it likewiſe differs very greatly in its qualities and colours. In ſome places it is found in thick laminæ, or flakes; while in others it is thin and light. The colours are white, brown, and blue.

It is ſo durable, in ſome caſes, as to have been known to continue ſound and good for centuries. However, unleſs it ſhould be brought from a quarry of well reputed goodneſs, it is neceſſary to try its properties, which may be done by ſtriking the ſlate ſharply againſt a large ſtone, and if it produce a complete ſound, it is a mark of goodneſs; but if in hewing it does not ſhatter before the edge of the *ſect*, or inſtrument commonly uſed for that purpoſe, the criterion is deciſive. The goodneſs of ſlate may be farther eſtimated by its colour: the deep black-blue is apt to imbibe moiſture, but the lighter blue is always the leaſt penetrable: the touch alſo may be in ſome degree a guide, for a good firm ſtone feels ſomewhat hard and rough, whereas an open ſlate feels very ſmooth, and as it were greaſy. And another method of trying the goodneſs of ſlate, is to place the ſlate-ſtone lengthwiſe, and perpendicularly in a tub of water, about half a foot deep, care being taken that the upper or unimmerſed part of the ſlate be not accidentally wetted by the hand, or otherwiſe; let it remain in this ſtate twenty-four hours; if good and firm ſtone, it will not draw water more than half an inch above the ſurface of the water, and that perhaps at the edges only, thoſe parts having been a little looſened in the hewing; but a ſpongy defective ſtone will draw water to the very top. There is ſtill another mode, held to be infallible. Firſt, weigh two or three of the moſt ſuſpected ſlates, noting the weight; then immerge them in a veſſel of water twelve hours; take them out, and wipe them as clean as poſſible with a linen cloth; and if they weigh more than at firſt, it denotes that quality of ſlate which imbibes water: a drachm is allowable in a dozen pounds, and no more.

It may be noticed, that in laying of this material, a buſhel and a half of lime, and three buſhels of freſh-water ſand, will be ſufficient for a ſquare of work; but if it be pin plaſtered, it will take above as much more: but good ſlate, well laid and plaſtered to the pin, will lie an hundred years; and on good timber a much longer time. It has been common to lay the ſlates dry, or on moſs only, but they are much better when laid with plaſter. When they are to be plaſtered to the pin, then about the firſt quantity of lime and ſand will be ſufficient for the purpoſe, when well mixed and blended together, by properly working them.

Slates differ very much in thickneſs as well as colour, which ſuits them for different ſituations and purpoſes. A great deal of good ſlate of various kinds is raiſed in different parts of Wales, and much excellent blue and other coloured ſorts is procured from the northern parts of Lancaſhire, and other neighbouring places, as well as from different other counties throughout the kingdom. In ſome parts the ſlate is diſtributed into three kinds, as the beſt, the middling, and the waſte or common ſort. See QUARRY.

SLATE-*Axe*, provincially a mattock with a ſhort axe-end, uſed in ſlating, &c.

SLATE *Mount*, in *Geography*, a mountain of Virginia; 6 miles W. of Richmond. N. lat. 37° 35′. W. long. 72°.

SLATE *River*, a river of Virginia, which runs into James river, N. lat. 37° 40′. E. long. 78° 34′.

SLATEE, an African appellation of free black merchants, often traders in ſlaves.

SLATERS, in *Entomology*. See MILLEPEDES and ONISCUS.

SLATERS *and Tilers*, are thoſe artificers who are employed in ſlating or tiling houſes. In calculating and eſtimating the value of their work, they find the content of a roof by multiplying the length of the ridge by the girt over from eaves to eaves; making allowance in this girt for the double row of ſlates at the bottom, or for the quantity or ſpace by which one row of ſlates or tiles is laid over another. In angles formed in a roof, running from the ridge to the eaves, when the angle bends inwards, it is called a valley; but when outwards, it is called a hip. And in tiling and ſlating, it is common to add the length of the valley or hip to the content in feet. Deductions are ſeldom made for chimney-ſhafts, or ſmall window-holes. *E. gr.* Required the content of a ſlated roof, the length being 45 feet 9 inches, and whole girt 34 feet 3 inches.

SLATINA, in *Geography*, a town of Bohemia, in the circle of Schlan; 6 miles E. of Schlan.—Alſo, a town of Walachia, on the E. ſide of the river Alaut; 2 miles N.E. of Brancovani.—Alſo, a town of European Turkey, in Moldavia; 18 miles N.W. of Niemecz.

SLATTBOG, a town of Sweden, in the province of Smaland; 15 miles N.W. of Wexio.

SLATY ROCK, or *Schiſtus*, in *Agriculture*, a ſubſtance of a mouldering, enriching nature, which is ſometimes blended up with other matters as a compoſt for land. The ſort of material of this kind which forms the under-ſoil in many parts of Cornwall, and ſome other diſtricts, is of an argillaceous, unctuous, ſoapy quality; which in ſome caſes is ploughed up with a ſtrong plough; and after being well expoſed to the ſummer ſun and winter froſt, is mixed with lime or ſand; in which ſtate it is ſaid to become a very capital thickener and fertilizer of thin poor worn-out ſoils, and by which much improvement is afforded at little trouble or expence.

SLAVANESS, in *Geography*, a cape on the E. coaſt of the iſland of Shetland. N. lat. 60° 31′. W. long. 1° 13′.

SLAVE, a perſon in the abſolute power of a maſter, with regard to his life, liberty, and fortune. See SERVANT.

Menage and Voſſius derive the word from *Sclavus*, the name of a Scythian people, whom Charlemagne condemned to perpetual impriſonment. See SCLAVONIC.

The Romans called their ſlaves, *ſervi*, from *ſervare, to keep*, or *ſave*; as being ſuch as were not killed, but ſaved to yield money, either by ſale, or by their work. Though other authors are of opinion, that the Roman name *ſervi* might come from that of *ſerbi*; as that of ſlaves from *Sclavi, a people.*

The term for a ſlave born and bred in the family, was *verna*; equivalent to *ſcurra*, denoting the petulance and impudence of theſe ſlaves. They ſeem to have been entitled by cuſtom to privileges and indulgences beyond others.

Among the Romans, when a ſlave was ſet at liberty, he changed his name into a ſurname; he took the nomen or prenomen of his maſter, to which he added the cognomen he had been called by when a ſlave. See NAME.

Among thoſe who were denominated ſlaves in the more lax and general uſe of the term, we may reckon thoſe who were diſtinguiſhed among the Romans by the appellation of "mercenarii," ſo called from the circumſtance of their *hire.* Theſe were free-born citizens, mentioned in the law-books by the name of *liberi*, and thus contradiſtinguiſhed from the *alieni*, or foreigners, who, from the various contingencies of fortune, were under a neceſſity of recurring for ſupport to the ſervice of the rich. To this claſs belonged thoſe who, both among the Jews and Egyptians, are recorded in the ſacred writings. (Gen. ch. xlvii. Levit. xxv. 39, 40.) The Grecian *Thetes* (θητες, ſee Hom. Odyſſ. Δ. 642.) were alſo of this deſcription. The ſituation of theſe perſons reſembled that of our ſervants; a contract ſubſiſting between the parties, and moſt of the ſubordinate dependants having a right to demand and obtain their diſcharge if they were ill uſed by their maſters.

Among the ancients there was another claſs of ſervants, which conſiſted wholly of thoſe who had ſuffered the loſs of liberty from their own imprudence. Such were the Grecian *prodigals*, who were detained in the ſervice of their creditors, till the fruits of their labour were equivalent to their debts; the *delinquents*, who were ſentenced to the oar; and the German *enthuſiaſts*, mentioned by Tacitus, who were ſo addicted to gaming, that when they had parted with every thing, alſo ſtaked their liberty and their perſons. "The loſer," ſays the hiſtorian, "goes into a voluntary ſervitude; and though younger and ſtronger than the perſon with whom he played, patiently ſuffers himſelf to be bound and ſold. Their perſeverance in ſo bad a cuſtom is ſtyled *honour.* The ſlaves thus obtained are immediately exchanged away in commerce, that the winner may get rid of the ſcandal of his victory." The two claſſes now enumerated comprehend thoſe that may be called *voluntary* ſlaves, and they are diſtinguiſhed from thoſe denominated *involuntary* ſlaves; who are forced, without any previous condition or choice, into a ſituation, which, as it tended to degrade a part of the human ſpecies, and to claſs it with the brutal, muſt have been, of all ſituations to which a human being can be reduced, the moſt wretched and inſupportable.

We find no mention of ſlaves before the Deluge, but immediately after, *viz.* in the curſe of Canaan, Gen. ix. 25; whence it is eaſily inferred, that ſervitude commenced ſoon after that time; for in Abraham's days we find it generally eſtabliſhed. Some will have it to have commenced under Nimrod, becauſe it was he who firſt began to make war, and of conſequence to make captives; and to bring ſuch as he took, either in his battles or irruptions, into ſlavery.

"Proud Nimrod firſt the bloody chace began,
Almighty hunter, and his prey was man." Pope.

Hence probably aroſe the connection between victory and ſervitude, an idea of which has prevailed among the nations of antiquity, and which has uniformly exiſted, in one country or another, to the preſent day. Accordingly, the firſt claſs of *involuntary* ſlaves, included thoſe who were "priſoners of war;" and theſe were more ancient than the *voluntary* ſlaves, who are firſt mentioned in the time of Pharaoh. The practice of reducing priſoners of war to the condition of ſlaves, ſubſiſted both among the eaſtern nations and the people of the Weſt; for as the Helots became the ſlaves of the Spartans, merely from the right of conqueſt, ſo priſoners of war were reduced to the ſame ſituation by the other inhabitants of Greece. The Romans, alſo, were actuated by the ſame principle; and all thoſe nations which contributed to overturn the empire, adopted a ſimilar cuſtom; ſo that it was a general maxim in their polity, that thoſe who fell under their power as priſoners of war, ſhould immediately be reduced to the condition of ſlaves. See PRISONERS *of War.*

The ſlaves of the Greeks were generally, or very commonly, barbarians, and imported from foreign countries.

By the civil law, the power of making ſlaves is eſteemed a right of nations, and follows, *jure gentium*, as a natural conſequence of captivity in war. "Jure gentium ſervi noſtri ſunt, qui ab hoſtibus capiuntur." Juſtinian, l. i. 5. 5. 1.

This is the firſt origin of the right of ſlavery aſſigned by

Juſtinian, Inſt. i. 3, 4. whence ſlaves are called *mancipia quaſi manu capti*.

The conqueror, ſay the civilians, had a right to the life of his captive; and having ſpared that, has a right to deal with him as he pleaſes. But this poſition, taken generally, is denied by judge Blackſtone; who obſerves, that a man has a right to kill his enemy only in caſes of abſolute neceſſity, for ſelf-defence: and, it is plain, this abſolute neceſſity did not ſubſiſt, ſince the victor did not kill him, but made him priſoner. Since, therefore, the right of making ſlaves by captivity depends on a ſuppoſed right of ſlaughter, that foundation failing, the conſequence drawn from it muſt fail likewiſe. Farther, it is ſaid that ſlavery may begin "jure civili," when one man ſells himſelf to another: but this, when applied to ſtrict ſlavery, in the ſenſe of the laws of old Rome or modern Barbary, is alſo impoſſible. Every ſale implies a price, a *quid pro quo*, an equivalent given to the ſeller in lieu of what he transfers to the buyer; but what equivalent can be given for life and liberty, both of which, in abſolute ſlavery, are held to be at the maſter's diſpoſal? His property, alſo, the very price he ſeems to receive, devolves *ipſo facto* to his maſter the inſtant he becomes his ſlave: and beſides, if it be not lawful for a man to kill himſelf, becauſe he robs his country of his perſon, for the ſame reaſon he is not allowed to barter his freedom: the freedom of every citizen conſtitutes a part of the public liberty. In this caſe, therefore, the buyer gives nothing, and the ſeller receives nothing; of what validity then can a ſale be, which deſtroys the very principles upon which all ſales are founded? Laſtly, we are told, that beſides theſe two ways by which ſlaves "fiunt," or are acquired, they may alſo be hereditary, "ſervi naſcuntur;" the children of acquired ſlaves are, *jure naturæ*, by a negative kind of birthright, ſlaves alſo; but this being founded on the two former rights, muſt fall together with them. If neither captivity, nor the ſale of one's ſelf, can, by the law of nature and reaſon, reduce the parent to ſlavery, much leſs can they reduce the offspring. Blackſt. Comm. b. i. c. 14. Monteſquieu's Spirit of Laws, b. 15. c. 2, &c.

The Lacedæmonians, ſay ſome, or, as others ſay, the Aſſyrians, firſt introduced the practice; which the Romans not only approved of, but they even invented new manners of making ſlaves; for inſtance, a man born free among them might ſell his freedom, and become a ſlave. This voluntary ſlavery was firſt introduced by a decree of the ſenate, in the time of the emperor Claudius, and at length was abrogated by Leo.

The Romans had power of life and death over their ſlaves, which no other nations had; but this ſeverity was afterwards moderated by the laws of the emperors; and by one of Adrian it was made capital to kill a ſlave without a cauſe.

The ſlaves were eſteemed the proper goods of their maſters, and all they got belonged to them: but if the maſter were too cruel in his domeſtic corrections, he was obliged to ſell his ſlave at a moderate price.

The cuſtom of expoſing old, uſeleſs, or ſick ſlaves in an iſland of the Tyber, there to ſtarve, ſeems to have been pretty common in Rome; and whoever recovered, after having been ſo expoſed, had his liberty given him, by an edict of the emperor Claudius, in which it was likewiſe forbidden to kill any ſlave merely for old age or ſickneſs. (Suet. in Claud.) Neverthleſs, it was the profeſſed maxim of the elder Cato, to ſell his ſuperannuated ſlaves for any price, rather than maintain what he deemed an uſeleſs burden. (Plut. in Caton.) The ergaſtula, or dungeons, where ſlaves in chains were forced to work, were very common all over Italy. Columella (l. i. c. 6.) adviſes that they be always built under ground; and recommends it as the duty of a careful overſeer, to call over every day the names of theſe ſlaves, in order to know when any of them had deſerted. Sicily was full of ergaſtula, and was cultivated by labourers in chains. Eunus and Athenio excited the ſervile war, by breaking up theſe monſtrous priſons, and giving liberty to 60,000 ſlaves.

In the ancient and uncivilized ages of the world, "piracy" was regarded as an honourable practice; and this was ſuppoſed to give a right of making ſlaves. "The Grecians," ſays Thucydides (l. i.) "in their primitive ſtate, as well as the contemporary barbarians, who inhabited the ſea-coaſts and iſlands, addicted themſelves wholly to it: it was, in ſhort, their only profeſſion and ſupport." The writings of Homer are ſufficient to eſtabliſh this account; as they ſhew that this was a common practice at ſo early a period as that of the Trojan war. The reputation which piracy ſeems to have acquired among the ancients, was owing to the ſkill, ſtrength, agility, and valour, which were neceſſary for conducting it with ſucceſs; and the erroneous notions that were thus entertained concerning it led to other conſequences, immediately connected with the ſlavery of the human ſpecies. Avarice and ambition availed themſelves of theſe miſtaken notions; and people were robbed, ſtolen, and even murdered, under the pretended idea that theſe were reputable adventures. But in proportion as men's ſentiments and manners became more refined, the practice of piracy loſt its reputation, and began gradually to diſappear. The practice, however, was found to be lucrative; and it was continued, with a view to the emolument attending it, long after it ceaſed to be thought honourable, and when it was ſinking into diſgrace. The profits ariſing from the ſale of ſlaves preſented a temptation which avarice and intereſt could not reſiſt; many were ſtolen by their own countrymen, and ſold for ſlaves; and merchants traded on the different coaſts in order to facilitate the diſpoſal of this article of commerce. The merchants of Theſſaly, if we may credit Ariſtophanes, (Plut. Act ii. Sc. 5.) who never ſpared the vices of the times, were particularly infamous for this latter kind of depredation; the Athenians were notorious for the former; for they had practiſed theſe robberies to ſuch an alarming degree of danger to individuals, that it was found neceſſary to enact a law, which puniſhed kidnappers with death. From the above ſtatement it appears, that among the ancients there were two claſſes of involuntary ſlaves; one conſiſting of thoſe who were taken publicly in a ſtate of war; and another compoſed of thoſe who were privately ſtolen in a ſtate of peace. To which might be added a third claſs, comprehending the children and deſcendants of the former.

The condition of ſlaves, and their perſonal treatment, were ſufficiently humiliating and grievous; and may well excite our pity and abhorrence. They were beaten, ſtarved, tortured, and murdered at diſcretion; they were dead in a civil ſenſe; they had neither name nor tribe; they were incapable of judicial proceſs; and they were, in ſhort, without appeal. To this cruel treatment, however, there were ſome exceptions. The Egyptian ſlave, though perhaps a greater drudge than any other, yet if he had time to reach the temple of Hercules (Herodotus, l. ii. 143.), found a certain retreat from the perſecution of his maſter; and he derived additional comfort from the reflection that his life could not be taken with impunity. But no place was ſo favourable to ſlaves as Athens. Here they were allowed a greater liberty of ſpeech; they had their convivial meetings, their amours, their hours of relaxation, pleaſantry, and mirth; they were treated in ſuch a manner as to warrant the obſervation of Demoſthenes, in his ſecond Philippic, " that the condition of a ſlave at Athens was preferable to that of a free citizen in many other countries." And here, if perſecution exceeded the bounds of lenity, they had their temple, like the Egyptian, for refuge; where the legiſlature was ſo attentive, as to examine their complaints, and to order them, if they were founded in juſtice, to be ſold to another maſter. Beſides, they were allowed an opportunity of working for themſelves; and if their diligence had procured them a ſum equivalent to their ranſom, they could immediately, on paying it down, demand their freedom for ever. To this privilege Plautus alludes, in his " Caſina," where he introduces a ſlave, ſpeaking in the following manner:

> " Quid tu me vero libertate territas?
> Quod ſi tu nolis, filiuſque etiam tuus
> Vobis *invitis*, atque amborum *ingratiis*,
> *Una libella liber poſſum fieri.*"

Thus we find, to the eternal honour of Egypt and Athens, that they were the only places, if we except the cities of the Jews, where ſlaves were conſidered with any humanity at all. The inhabitants of all other parts of the world ſeemed to vie with each other in the debaſement and oppreſſion of theſe unfortunate people.

The writer, of whoſe valuable publication we are now availing ourſelves, and to whom the cauſe of humanity is under inexpreſſible obligations, proceeds to inquire by what circumſtances the barbarous and inhuman treatment of ſlaves was produced?

The firſt of theſe circumſtances, which he mentions, was " commerce;" for if men could be conſidered as " poſſeſſions;" if, like " cattle," they might be *bought* and *ſold*, it will be natural to ſuppoſe, that they would be regarded and treated in the ſame manner. This kind of commerce, which began in the primitive ages of the world, depreſſed the human ſpecies in the general eſtimation; and they were tamed, like brutes, by the ſtings of hunger and the laſh, and their education was ſo conducted, as to render them commodious inſtruments of labour for their poſſeſſors. This degradation of courſe depreſſed their minds, reſtricted the expanſion of their faculties, ſtifled almoſt every effort of genius, and exhibited them to the world, as beings endued with inferior capacities to the reſt of mankind. But for this opinion there ſeems to have been no foundation in truth or juſtice. Equal to their fellow-men in natural talents, and alike capable of improvement, any apparent or even real difference between them and ſome others muſt have been owing to the mode of their education, to the rank they were doomed to occupy, and to the treatment they were appointed to endure.

This commerce of the human ſpecies, which produced ſo pernicious an effect on the nature and ſtate of man, commenced at a very early period. The hiſtory of Joſeph, recorded in the book of Geneſis, leads us to a very remote era for the introduction of this nefarious traffic. In his time it ſeems to have been prevalent, and to have been carried on in a manner, that ſufficiently indicated its having been long before eſtabliſhed. Egypt ſeems to have been at this time the principal, as it was probably the firſt, market for the ſale of the human ſpecies. It was, indeed, ſo famous, as to have been known, within a few centuries from the time of Pharaoh, both to the Grecian colonies in Aſia, and the Grecian iſlands. Homer mentions Cyprus and Egypt as the common markets for ſlaves, about the time of the Trojan war. (Odyſſ. l. xvii. 448. l. xxvi.) Egypt is alſo repreſented, as we have already intimated, in the book of Geneſis, as a market for ſlaves, and in Exodus (ch. i.) as famous for the ſeverity of its ſervitude. Homer alſo, in the place above cited, points out to us Egypt as a market for the human ſpecies, and by the epithet of " *bitter* Egypt," alludes in the ſtrongeſt manner to that ſeverity and rigour, of which the ſacred hiſtorian tranſmitted to us the firſt account. The Odyſſey of Homer ſhews farther, that this ſpecies of traffic was practiſed in many of the iſlands of the Ægean ſea; and the Iliad informs us, that it had taken place among thoſe Grecians on the continent of Europe, who had embarked from thence on the Trojan expedition. To this purpoſe, at the end of the ſeventh book, a fleet is deſcribed, as having juſt arrived from Lemnos, with a ſupply of wine for the Grecian camp. The merchants are deſcribed alſo, as immediately expoſing it to ſale, and as receiving in exchange, among other articles of barter, " a number of ſlaves." Tyre and Sidon, as we learn from the book of Joel, ch. iii. 3, 4, 6, were notorious for the proſecution of this trade. This cuſtom appears alſo to have exiſted among other ſtates; it travelled all over Aſia; it ſpread through the Grecian and Roman world; it was in uſe among the barbarous nations, which overturned the Roman empire; and was therefore practiſed, at the ſame period, throughout the whole of Europe. However, as the northern nations were ſettled in their conqueſts, the ſlavery and commerce of the human ſpecies began to decline, and on their full eſtabliſhment they were aboliſhed. Some writers have aſcribed their decline and abolition to the prevalence of the feudal ſyſtem; whilſt others, much more numerous, and with greater ſtrength of argument, have maintained, that they were the natural effects of Chriſtianity. The advocates of the former opinion allege, that " the multitude of little ſtates, which ſprung up from one great one at this era, occaſioned infinite bickerings and matter for contention. There was not a ſtate or ſeigniory, which did not want all the hands they could muſter, either to defend their own right, or to diſpute that of their neighbours. Thus every man was taken into the ſervice: whom they armed they muſt truſt: and there could be no truſt but in free men. Thus the barrier between the two natures was thrown down, and ſlavery was no more heard of in the weſt."

That this was not the neceſſary conſequence of ſuch a ſituation, is apparent. The political ſtate of Greece, in its early hiſtory, was the ſame as that of Europe, when divided by the feudal ſyſtem into an infinite number of ſmall and independent kingdoms. There was the ſame matter, therefore, for contention, and the ſame call for all the hands that could be muſtered: the Grecians, in ſhort, in the heroic, were in the ſame ſituation, in theſe reſpects, as the feudal barons in the Gothic times.

It muſt be allowed, on the ſlighteſt conſideration of the ſubject, that Chriſtianity was admirably adapted to this purpoſe. It taught, " that all men were originally equal; that the Deity was no reſpecter of perſons; and that, as all men were to give an account of their actions hereafter, it was neceſſary that they ſhould be free." Theſe doctrines could not fail of having their proper influence on thoſe who firſt embraced Chriſtianity, from a conviction of its truth; and on thoſe of their deſcendants afterwards, who, by engaging in the cruſades, and hazarding their lives and fortunes there, ſhewed at leaſt an attachment to that religion. We find them accordingly actuated by theſe principles. We have a poſitive proof, that the feudal ſyſtem had no ſhare in the honour of ſuppreſſing ſlavery, but that Chriſtianity was the only cauſe; for the greateſt part of the charters, which were granted for the freedom of ſlaves in thoſe times (many of which are ſtill extant), were granted "pro amore Dei, pro mercede animæ." They were founded, in ſhort, on religious conſiderations, "that they might procure the favour of the Deity, which they conceived themſelves to have forfeited, by the ſubjugation of thoſe, whom they found to be the objects of the divine benevolence and attention equally with themſelves."

Theſe conſiderations, which had thus their firſt origin in Chriſtianity, began to produce their effects, as the different nations were converted; and procured that general liberty at laſt, which, at the cloſe of the twelfth century, was conſpicuous in the weſt of Europe.

Within two centuries after the ſuppreſſion of ſlavery in Europe, the Portugueſe, in imitation of thoſe piracies which exiſted in the uncivilized ages of the world, made their deſcents on Africa, and committing depredations on the coaſt, firſt carried the wretched inhabitants into ſlavery. This practice, thus inconſiderable at its commencement, became general; and our own anceſtors, together with the Spaniards, French, and moſt of the maritime powers of Europe, ſoon followed the piratical example: and thus did the Europeans, to their eternal infamy, revive a cuſtom, which their own anceſtors had ſo lately exploded, from a conſciouſneſs of its impiety. The unfortunate Africans fled from the coaſt, and ſought, in the interior part of the country, a retreat from the perſecution of their invaders; but the Europeans ſtill purſued them; they entered their rivers, ſailed up into the heart of the country, ſurpriſed the Africans in their receſſes, and carried them into ſlavery. The next ſtep, which the Europeans found it neceſſary to take, was that of ſettling in the country; of ſecuring themſelves by fortified poſts; of changing their ſyſtem of force into that of pretended liberality; and of opening, by every ſpecies of bribery and corruption, a communication with the natives. Accordingly they erected their forts and factories; landed their merchandize; and endeavoured, by a peaceable deportment, by preſents, and by every appearance of munificence, to allure the attachment and confidence of the Africans.

The Portugueſe erected their firſt fort at D'Elmina, in the year 1481, about 40 years after Alonzo Gonzales had pointed out to his countrymen the ſouthern Africans as articles of commerce.

The ſcheme ſucceeded: an intercourſe took place between the Europeans and Africans, attended with a confidence highly favourable to the views of ambition and avarice. In order to render this intercourſe permanent as well as lucrative, the Europeans having diſcovered the chiefs of the American tribes, paid their court to theſe; and at length a treaty of peace and commerce was concluded; in which it was agreed, that the kings, on their part, ſhould, from this period, ſentence *priſoners of war* and *convicts* to European ſervitude; and that the Europeans ſhould ſupply them, in return, with the luxuries of the north. This agreement immediately took place, and laid the foundation of that commerce, of which the following articles contain a brief hiſtory.

Slavery is abſolutely aboliſhed in England and France as to perſonal ſervitude; our ſervants are not ſlaves, but only are ſubject to certain determinate ſervices. It is ſaid, that the moment a ſlave ſteps on Engliſh ground, he by law becomes free. See NEGRO.

When an attempt was made to introduce ſlavery within this nation, by ſtat. 1 Edw. VI. c. 3. which ordained, that all idle vagabonds ſhould be made ſlaves, and fed upon bread, water or ſmall drink, and refuſe of meat; ſhould wear a ring of iron round their necks, arms, or legs; and ſhould be compelled, by beating, chaining, or otherwiſe, to perform the work aſſigned them, were it ever ſo vile; the ſpirit of the nation could not brook this condition, even in the moſt abandoned rogues; and, therefore, this ſtatute was repealed in two years afterwards. 3 & 4 Edw. VI. c. 16.

For the cuſtom of marking or ſtigmatizing ſlaves, ſee STIGMATIZING.

SLAVE-TRADE. At the cloſe of the preceding article we have ſtated the manner in which this ſpecies of commerce commenced; nor is it neceſſary to mention one oſtenſible reaſon that was alleged for introducing the Africans, in particular, as labourers into the newly diſcovered parts of the weſtern world, and placing them under European maſters, *viz. the duty of converting the heathen;* becauſe this was but an idle pretence. It was ſoon found that a uſage, different from that which Chriſtianity would have dictated, was neceſſary, where people were tranſported, and made to labour againſt their will. A ſyſtem, therefore, of ſeverity ſprung up, as it related to their treatment, which became by degrees ſtill more cruel and degrading; ſo that when in after-times the ſituation of maſter and ſlave came to be viewed, as it exiſted in practice between the two, the maſters ſeemed to have attained the rank of monarchs, and the ſlaves to have gone down to the condition of brutes. Hence, very early after the commencement of the ſlave-trade, the objects of it began to be conſidered as an inferior ſpecies, and even their very colour as a mark of it; and under this latter notion they continued to be tranſported for years and years, till different perſons, taking an intereſt in their ſufferings, produced ſuch an union of public ſentiment in their favour in England, that the parliament there were obliged, as it were, to conſider their caſe, by hearing evidence upon it. It is from this evidence, as from the higheſt authority, which was heard in the years 1791 and 1792, that we ſhall chiefly give our account of the trade in queſtion.

The treaty to which we have referred, ſtipulated to ſupply the Europeans with captives and convicts; but theſe were not ſufficient for their demand, on the eſtabliſhment of their weſtern colonies. In order, therefore, to augment the number, not only thoſe who were fairly convicted of offences were now ſentenced to ſervitude, but even thoſe who were ſuſpected; and with regard to priſoners of war, they delivered into ſlavery not only thoſe who were taken in a ſtate of public enmity and injuſtice, but thoſe alſo who, conſcious of no injury whatever, were taken in the arbitrary ſkirmiſhes of the venal ſovereigns of Africa. Wars were made, not as formerly, from motives of retaliation and defence, but for the ſake of obtaining priſoners alone, and the advantages reſulting from the ſale of them. When an European ſhip came in ſight, this was conſidered as a motive for war, and a ſignal for the commencement of hoſtilities. The deſpotic ſovereigns of Africa, influenced by the venal motives of European traffic, firſt made war upon the neighbouring tribes, in the violation of every principle of juſtice; and if they did not thus ſucceed in their main object, they turned their arms againſt their own ſubjects. The firſt villages at which they arrived were immediately ſurrounded, and afterwards ſet on fire; and the wretched inhabitants ſeized, as they were eſcaping from the flames. Theſe, conſiſting of whole families, fathers, brothers, huſbands, wives, and children, were inſtantly driven in chains to the merchants, and conſigned to ſlavery. Many other perſons were kidnapped, in order to glut the avarice of their own countrymen, who lay in wait for them; and they were afterwards ſold to the European merchants:

while the ſeamen of the different ſhips, by every poſſible artifice, enticed others on board, and tranſported them to the regions of ſervitude.

The collectors of ſlaves were diſtributed into ſeveral claſſes. The firſt conſiſted of ſuch black traders as preſerved a regular chain of traffic, and a regular communication with each other, from the interior parts of the country to the ſea-ſhore. Many of the ſlaves, thus driven down, are reported to have travelled at leaſt 1200 miles from the place where they were firſt purchaſed. A piſtol or a ſword may have been the full value of one of theſe ſlaves, at the firſt coſt; but his price advances, as he travels towards the ſea-ſhore. The ſecond claſs of ſlave-traders is compoſed of ſuch as travel inland, but have no chain of commerce or communication with the ſhore. At a certain diſtance they ſtrike off in a line parallel to the ſhore, and viſiting the fairs and villages in their way, drop down occaſionally to the coaſt, as they have procured ſlaves. The third claſs conſiſts of ſuch as travel by water up the great rivers, in their canoes, which are very long, well-armed, and carry from 50 to 70 hands. Theſe often proceed to the diſtance of 1000 miles, and bring down from 60 to 120 ſlaves at a time. The fourth claſs includes thoſe who, living near the banks of the rivers, or the ſea-ſhore, ſcarcely travel at all, but coming by ſome means or other into the poſſeſſion of ſlaves, either drive them, or ſend them immediately to the ſhips and factories. Moſt of the traders now deſcribed traffic on their own account; but there are ſome of the poorer ſort, who travel for the ſhips. The different ſorts of goods, with which the traders deal for ſlaves in the inland country, may be divided into three ſorts, *viz.* Eaſt Indian, home-made or colonial, and Venetian. The firſt conſiſts of cowries, or ſmall ſhells, which paſs for money on ſome parts of the coaſt; blue and white baffs, romals, bandanoes, and other cloths and productions of the Eaſt. The ſecond conſiſts of bar-iron, muſkets, powder, ſwords, pans, and other hardware; cottons, linen, ſpirits in great abundance, with other articles of leſs note. The third conſiſts totally of beads. Almoſt every ſhip carries the three ſorts of articles now ſtated, but more or leſs of one than of the other, according to the place of her deſtination; every different part of the coaſt requiring a different aſſortment, and the Africans, like the Europeans, repeatedly changing their taſte. This is particularly the caſe with reſpect to beads. The ſame kind of beads, which finds a market one year in one part of the coaſt, will probably not be ſaleable there the next. At one time the green are preferred to the yellow, at another the opaque to the tranſparent, and at another the oval to the round.

The ſlave-trade, at the time of its ſubſiſtence, may be ſaid to have begun at the great river Senegal, and to extend to the farther limits of Angola, a diſtance of many thouſand miles. On the rivers Senegal and Gambia, the Europeans proceed in their ſhips till they come to a proper ſtation, and then ſend out their boats armed to different villages; and on their approach to them, fire a muſket, or beat a drum, to appriſe the inhabitants that they are in want of ſlaves. The country people ſupply them in part, and they alſo procure them from the large canoes above-mentioned.

The Moors, who inhabit the left bank of the river Senegal, are notorious for depredations of this ſort. They croſs the river without any previous provocation, and make war upon thoſe on the other ſide of it, and bring them in as priſoners, and ſell them at Fort St. Louis for ſlaves. Mr. Kiernan has ſeen the remains of villages, which they had broken up in ſuch expeditions.

Captains Hills and Wilſon, and Mr. Wadſtrom, and lieutenant Dalrymple, inform us, that the kings in this part of the country do not heſitate to make war upon their own ſubjects, when in want of money. They ſend out their ſoldiers in the night, who lying before, or attacking or burning a village, ſeize ſuch as come out of it, and return with them as ſlaves.

On the river Sierra Leona there are ſeveral private factories, belonging to the merchants of Europe, in which their agents, being white people, reſided. Theſe agents kept a number of boats, which were ſent up the river for ſlaves; and thus they procured for the factories a regular ſupply.

On the Windward Coaſt, which reaches from Cape Mount to Cape Palmas, the natives, when they have any ſlaves to ſell, generally ſignify it by fires. Practices ſimilar to thoſe already recited prevail from the river Gambia to the end of the Windward Coaſt. Lieutenant Storey ſays, that public robbery is here called war. Mr. Bowman, another evidence, ſays, that when parties of robbers were ſetting fire to villages, war was ſaid to be carrying on. This account is confirmed by Mr. Town and ſir George Young, and all of them concur in ſtating, that theſe parties go out at night, break up villages, and carry off the inhabitants as ſlaves. Meſſrs. Town, Bowman, and Storey, have ſeen them ſet out upon ſuch expeditions; and the latter, to ſatisfy himſelf, accompanied them on one occaſion. Theſe came to a town in the dead of the night, ſet fire to it, and took away many of the inhabitants. The above practice is ſo common, that both up the river Scaſſus, Sierra Leona, and Junk, and at Cape Mount and Baſſau, the remains of burnt and deſerted villages are to be ſeen, on which ſuch attacks have been made, and that the natives are found to be conſtantly armed. In one of the towns, two or three houſes only are deſcribed to have been left ſtanding, and two plantations of rice, which were ready for cutting down, but which the inhabitants, by being carried off, had been deprived of enjoying. Lieutenant Simpſon, of the royal marines, another evidence, underſtood that the villages on the Windward Coaſt were always at war; and the reaſon given was, that the kings were in want of ſlaves. Mr. Morley, another evidence, ſpeaks in the ſame language. Slaves, he ſays, are generally made by robbers going from village to village in the night.

The Gold Coaſt, which is next to the Windward Coaſt, preſents us with the ſame melancholy ſcene. The Rev. Mr. Quakoo, who had reſided as chaplain to one of the factories there for many years, informed lieutenant Simpſon that wars were often made for the ſole purpoſe of making ſlaves. Dr. Trotter ſays, by priſoners of war, the traders mean ſuch as are carried off by robbers, who ravage the country for that purpoſe; the Buſh-men making war to make trade, being a common way of ſpeaking among them; and in a large cargo of ſlaves, he could only recollect three who had not been ſo obtained. Surgeon Falconbridge defines the term war, when uſed by the ſlave-dealers on this part of the coaſt, to mean a piratical expedition for making ſlaves. Mr. Morley ſays, what they call war, is putting the villages in confuſion, and catching the inhabitants, whom they carry down to the coaſt and ſell, where, it is well known, no queſtions are aſked how they had been obtained. Indeed a ſlave-captain, when examined by the houſe of commons, acknowledged, that he believed a captain would be reckoned a fool by any trading man, to whom he ſhould put ſuch a queſtion. And Mr. Marſh, the reſident at Cape Coaſt caſtle, told Mr. How, that he did not care how the ſlaves he purchaſed had been obtained; and ſhewed him inſtruments which were put into the ſlaves' mouths, to prevent

vent their crying out for aſſiſtance, while the robbers were conveying them through the country.

From the end of the Gold Coaſt to the extremity of Angola, which is the boundary of the ſlave-trade, and which vaſt diſtrict comprehends many navigable rivers, we are ſhocked by the repetition of the ſame atrocious practices. Here, as before, going to towns in the night, ſetting them on fire, and ſeizing the people, or putting the villages in confuſion, and catching the inhabitants, are called *war*. Theſe piratical expeditions are frequently made by water in theſe parts. Mr. Douglaſs ſays, when a ſlave-ſhip arrives, the king ſends his war-canoes up the river, where they ſurpriſe and ſeize all they can. Surgeon Falconbridge, Mr. Morley, and Mr. Iſaac Parker, confirm the account. Up the great rivers Bonny and Calabar the king ſends fleets of canoes, with armed men, which return with ſlaves. Mr. I. Parker was twice up the river Calabar in one of theſe fleets, and perhaps the only white perſon who was ever permitted to go with them. In the day-time, he ſays, when they approached a village, they lay under the buſhes; but at night flew up to it, and ſeized every one they could catch. In this way they proceeded up the river, till they had gotten forty-five perſons, which they brought back to New Town, and ſold to the European ſhips. About a fortnight afterwards, he was allowed to accompany them on another expedition. Here, he ſays, they plundered other villages higher up the river than before, taking men, women, and children, as they could catch them in their huts. They ſeized on much the ſame number, and brought them to New Town, as before.

On the Gold Coaſt, a veſſel ſeeking ſlaves, generally anchors at Annamaboe. A certain quantity of gold muſt be included in the articles deſigned for purchaſing ſlaves, or elſe none can be obtained. At Whidah, Bonny, Calabar, Benin, and Angola, gold is not demanded in exchange; and boats are unneceſſary, except for reaching the ſhore, wooding and watering, and ſervices of a ſimilar kind. This is particularly the caſe at Calabar and Bonny, which have been the greateſt markets for ſlaves. The traders of the firſt claſs, after an abſence of about nine days, have returned frequently with 1500 or 2000 ſlaves at a time.

The number of ſlaves that have been annually tranſported from the African coaſt has fluctuated according to circumſtances. In the year 1768, 104,000 natives of Africa were taken from their own continent; and it continued much the ſame for the next five years. During the American war it was diminiſhed. In the year 1786 the numbers may be ſtated at 100,000, and the ſhips that conveyed them to the colonies at 350. The trade, before the abolition, was confined to the Engliſh, Dutch, Danes, Portugueſe, and French. England, in 1786, employed 130 ſhips, and carried off about 42,000 ſlaves. Theſe were fitted out from the ports of London, Briſtol, and Liverpool; the latter of which alone ſent out 90 veſſels.

The unhappy ſlaves are divided by Mr. Clarkſon into ſeven claſſes. The moſt conſiderable, and that which contains at leaſt half of the whole number tranſported, conſiſts of kidnapped people. This mode of procuring them includes every ſpecies of treachery. Mr. Wadſtrom tells us, that at Dakard lived one Ganna, who was a notorious man-ſtealer, and employed as ſuch by the merchants there. He ſaw a boy and a woman there in confinement, both of whom had been ſtolen. The boy had been privately taken from his parents, in the interior part above Cape Rouge; and the woman from her huſband and children at Ruffſque. He ſaw afterwards many of the natives, who had been thus taken, brought to Goree. At Sallum the king ſent for a poor woman, under pretence of buying her millet, and then ſeized and ſold her. General Rooke, who was governor of Goree, detected three young perſons who had been ſtolen and brought there; and at their requeſt, he ſent them back to their friends. The ſame governor was applied to by three ſlave-captains, to kidnap one hundred and fifty men, women, and children, the king of Cayor's ſubjects, who had come to Goree in conſequence of the friendly intercourſe which had ſubſiſted between him and that king. He refuſed, and was much ſhocked by the propoſition; but the captains ſaid, ſuch things had been done by a former governor of the place. Captain Wilſon ſays, that in his time, when he commanded the Racehorſe ſhip of war, ſuch private robberies were frequent on the continent, oppoſite to Goree. His predeceſſor, captain Lacy, had ſent one of the natives into the country with diſpatches on his Britannic majeſty's account; but the poor man was ſoon way-laid, ſeized, and ſold. Captain Wilſon reſcued him afterwards from the hold of a ſlave-veſſel, where his life had been endangered by the inhumanity of the French captain. So generally prevalent were theſe robberies, that they were acknowledged by all. It was the firſt principle of the natives, never to go out unarmed while a ſlave-veſſel was upon the coaſt, for fear of being ſtolen. When he has met them armed, and enquired the reaſon, they have pointed to a ſhip of this deſcription then lying at Portudal, and ſaid, their fears aroſe from that quarter. Captain Hills, when he commanded the Zephyr ſloop of war on the ſame part of the coaſt, came to the knowledge of facts ſimilar to thoſe related. He tells us, he knew the ſame Ganna mentioned by Mr. Wadſtrom, and that this very Ganna offered him a young man for ſale, whom he had kidnapped; and that all the natives went armed, for fear of being ſo taken. Captain Hills, while lying in the river Gambia, expreſſed a wiſh, in the hearing of the black pilot, to obtain a few black volunteers for his ſhip. Upon this the black pilot called to two boys, who were on the ſhore carrying baſkets of ſhallots, and aſked captain Hills if he thought the boys would ſuit him; in which caſe, he would take them off, and bring them on board. The captain declined taking them. The black pilot appeared much mortified, and ſaid that the merchantmen would not have refuſed ſuch an offer. On the Windward Coaſt, robbery of this kind was ſo notorious, that, according to ſir George Young and captain Thompſon, it went by a diſtinct name. It was there called *panyaring*. Many are the inſtances teſtified in the evidence of this kind of depredation, and this all over the coaſt. Let the following ſuffice. At Sierra Leona a beautiful boy is ſtolen. Off Galenas a trader, returning home with goods, is ſeized by the way, and ſold. Lower down a young man is ſurpriſed on the beach, and diſpoſed of in the ſame manner. Off Piccanini Seſtus not only a young girl is kidnapped, but her kidnapper is ſeized in turn, and ſold to the ſame veſſel. To the right of Piccanini Seſtus a young man is invited to a feaſt, and then betrayed and enſlaved. A little farther on, a countryman, having occaſion to go to a black trader's houſe, the trader aſks him if he had ſeen a ſhip: the other replying, no; he then engages to ſhew him one. Taking him on board a veſſel, he receives the money for him, and leaves him there. A young woman comes out of the woods at Bonny Point to bathe: robbers watch her, and then ſeize her, and ſell her. Three perſons, croſſing the river Benin, are overtaken by a black trader and his people in one of their large canoes, and carried to a ſhip, and ſold. On the other ſide of the river Benin, a woman is kidnapped, as ſhe is returning from a viſit; and a father and his ſon, as they are planting yams for food; and all of them paſſed down to the ſhore, and diſpoſed of in the ſame manner.

The ſecond order of ſlaves, and that not inconſiderable, conſiſts of thoſe whoſe villages have been depopulated for obtaining them. The third claſs conſiſts of ſuch as have been ſaid to be convicted of crimes. Captain Wilſon ſays, that ſuch as are ſold on this account are ſold for the benefit of their kings or judges. On aſking king Damel's officer, who had brought down a culprit for ſale, whether the man was guilty of the crime imputed to him, he was anſwered by the officer, that this was of no conſequence. Mr. Town ſays, it is not uncommon to impute crimes falſely, or to bring on palavers, that is, accuſations or trials, in order to make ſlaves. Mr. Morley remembers a woman ſold on pretence of adultery at Old Calabar; and in the river Ambris, ſays Mr. Falconbridge, a king's officer wanting brandy and other goods, but having no ſlave with which to purchaſe them, accuſes a man of extortion in the ſale of his fiſh, and after a ſummary trial on the ſpot, procures him to be condemned and ſold.

The fourth claſs includes priſoners of war; being either ſuch as are the produce of wars that have originated in common cauſes; or ſuch as have been ſupplied by wars made ſolely for the purpoſe of obtaining them. The fifth claſs comprehends thoſe who are ſlaves by birth. Some traders on the coaſt, it is ſaid, who have ſlaves in their poſſeſſion, make a practice of breeding from thoſe, for the purpoſe of ſelling to others. After having been brought up to a certain age, they are reckoned ſaleable. The ſixth claſs is compoſed of thoſe, who have ſacrified their liberty to gaming. The ſeventh and laſt claſs conſiſts of thoſe, who having run into debt, are ſeized according to the laws of the country, and ſold to their creditors. The two laſt claſſes are very inconſiderable, and ſcarcely deſerve mention.

Having loſt their liberty in one or other of the ways now deſcribed, they are conveyed to the banks of the rivers, or to the ſea-coaſt. Some are found to have belonged to the neighbourhood; others to have lived farther up the country; and others in very diſtant parts. It has been calculated, that ſome of the latter have been brought 1000 miles from their homes. Of thoſe who come from a diſtance, many have travelled by water, many have been made to walk alſo over land. Theſe march in droves, or cauffles, as they are called. They are ſecured from riſing or running away, by pieces of wood, which attach the necks of two and two together; or by other pieces, which are faſtened by ſtaples to their arms. They are made to carry their own water and proviſions, and ſome of them elephants' teeth, and other commodities, which their maſters may have picked up on their route. They are watched and followed by drivers, who make the weak keep up with the ſtrong. As they paſs through different places, others, who have been reduced to ſlavery in a ſimilar manner, are purchaſed, and added to the cauffle. Many in theſe cauffles ſpeak different languages, and cannot at all underſtand one another.

When they reach the banks of the rivers on the coaſt, they are offered for ſale: ſome to land factories, or depots kept for that purpoſe by the Europeans; others, where the rivers are ſmall and ſhallow, to ſhips' boats and tenders, which are conſtantly plying about to purchaſe them; and others immediately to the ſhips themſelves. In the rivers Senegal and Gambia, from ten to forty are brought down at a time; in the rivers Bonny and Calabar, from a thouſand to fifteen hundred; and on the Windward Coaſt, perhaps a ſolitary individual, or only two or three at a time; ſo that ſlaving, as it is called, is very tedious in that quarter. All thoſe, who are thus offered for ſale, undergo previous examination by a ſurgeon; and none are taken but ſuch as are free from diſorder, and in the prime of life. Indeed 25 years of age is the ſtandard, beyond which the purchaſers do not like to take them. In making their bargains, the goods as well as the ſlaves are valued by a medium, which is known to the parties concerned. From Senegal to the end of the Windward Coaſt, this medium is called a bar both by African and European brokers; on the Gold Coaſt and at Whidah, an ounce; at Calabar, a copper; at Benin, a pawn; and at Angola, a piece. Thus every ſlave is valued at ſo many bars, ounces, &c. Every piece of goods, every barrel of powder, every knife and cutlaſs, is valued in like manner. One article is marked half a bar or ounce; another a whole bar or ounce; another five, ten, twenty, and ſo on. By means of this arrangement, the bill is eaſily made out on both ſides. The Europeans reckon the amount by pen and ink; the Africans by ſmall ſtones or beads. Some of the latter, however, reckon entirely by their heads, and are found to be correct.

When the ſlaves are conveyed to the ſhore, they are carried in boats to the different ſhips whoſe captains have purchaſed them. The men are immediately confined two and two together, either by the neck, leg, or arm, with fetters of ſolid iron. They are then put into their apartments; the men occupying the fore-part, the women the after-part, and the boys the middle of the veſſel. The tops of theſe apartments are grated for the admiſſion of light and air, and they are ſtowed like any other lumber, occupying ſuch quantity of room as has been allotted to them. Many of them, whilſt the ſhips are waiting for their full lading, and whilſt they are near their native ſhore, from which they are to be ſeparated for ever, have manifeſted great appearance of oppreſſion and diſtreſs; and in ſome caſes have recurred, for apprehended relief, to ſuicide; others have been affected with delirium and madneſs; others, again, have been actuated by a ſpirit of revenge, and have reſolved on puniſhing their oppreſſors at the hazard of their own lives. In the day-time, if the weather be fine, they are brought upon deck for air. They are placed in a long row of two and two together, on each ſide of the ſhip; a long chain is then made to paſs through the ſhackles of each pair, by which means each row is at once ſecured to the deck. In this ſtate they take their meals, which conſiſt chiefly of horſe-beans, rice, and yams, with a little palm-oil and pepper. Captain Hall informs us, that they are made, after meals, to jump as high as their fetters will let them, on beating a drum. If they refuſe, they are whipped till they comply. This the ſlave-merchants call dancing. Surgeon Falconbridge explains to us the reaſon of this cuſtom, by ſtating that the ſlaves are compelled to jump for exerciſe; and ſurgeon Claxton ſays, that the parts on which the ſhackles are faſtened, are often excoriated by the violent exerciſe they are forced to take: and of this they made many grievous complaints to him. In the ſame manner the ſong is ſaid to be promoted among them; whereas all their ſongs, ſays ſurgeon Falconbridge, Mr. Morley, ſurgeon Claxton, Mr. Elliſon, and others, are of a melancholy nature, conſiſting of lamentations for the loſs of their country and of their friends.

When the number of ſlaves is completed, the ſhips weigh anchor, and begin what is termed the *Middle* paſſage, to carry them to their reſpective colonies. The veſſels in which they are tranſported are of different dimenſions, from 11 to 800 tons, and they carry from 30 to 1500 ſlaves at a time. The height of the apartments is different, according to the ſize of the veſſel, but may be ſtated to be from ſix feet to leſs than three; ſo that it is impoſſible to ſtand erect in moſt of the veſſels that tranſport them, and in ſome ſcarcely to ſit down in the ſame poſture.

When the veſſel is full, their ſituation is truly pitiable. A grown-up perſon is allowed, in the beſt regulated ſhips, but ſixteen Engliſh inches each in width, two (Engliſh) feet eight inches in height, and five feet eleven inches in length; or, as ſurgeon Falconbridge expreſſes himſelf, not ſo much room as a man has in his coffin. Surgeon Wilſon deſcribes the ſlaves as much crowded below. He generally took off his ſhoes before he went down among them, and was obliged to be very cautious how he walked, leſt he ſhould tread upon them. Captain Knox admits, that they had not room to lie on their backs. It alſo appears, that if they are the leaſt dilatory or reluctant in packing themſelves, they are quickened by the application of the whip. Dr. Trotter ſays, they are ſo crowded below, that it is impoſſible to walk through them without treading on them; and alſo, that it is the firſt mate's duty to ſee them ſtowed or packed together. Thoſe who do not get quickly into their places, are compelled by a cat-o'-nine-tails. But now their ſituation becomes too wretched to be deſcribed. No language has words to explain it properly. Captain Hall has often heard them cry out from below for want of air. The ſpace between decks was ſo hot, that often, after he has been there but a few minutes among them, he found his ſhirt ſo wetted by perſpiration, that he could have wrung it. Mr. Elliſon ſays, that the ſteam from their confined bodies below comes up through the gratings like a furnace. Surgeon Wilſon has often heard them complain of heat. The bad effects, which reſulted from this and their confinement, were weakneſs and fainting. He has ſeen ſome die a few minutes after being brought up, which proceeded from corrupted air and heat jointly. He has ſeen others go down apparently well at night, and found them dead in the morning. He had an hoſpital on board, but the ſick ſlaves were obliged to lie on the bare boards, ſo that the motion of the veſſel often occaſioned excoriations from the prominent parts of their bodies. Surgeon Falconbridge declares, that he has known ſlaves go down apparently in health, and brought up dead in the morning. He once opened one of them ſurgically, to diſcover with certainty what was the cauſe of his death; and found, from the appearance of the thorax and abdomen, that it was from ſuffocation. He ſays, that once on going below, he found that twenty of the ſlaves had fainted. He got them inſtantly hauled up on deck; but notwithſtanding the quickneſs of his movements on this occaſion, two or three of them died. And once, though he was only fifteen minutes in their room below, he became ſo ill himſelf, that he could not get up again to the deck without help; and he never was below many minutes together, but his ſhirt was as wet as if it had been dipt in water. He ſays alſo, that as the ſlaves, whether well or ill, always lie on the bare planks, the motion of the ſhip rubs the fleſh from the prominent parts of their body, and leaves the bones almoſt bare. And when the ſlaves have the flux, which is frequently the caſe, the whole place becomes covered with blood and mucus, like a ſlaughter-houſe; and as they are fettered and wedged cloſe together, the utmoſt diſorder ariſes from endeavours to get to three or four tubs, which are placed among them for neceſſary purpoſes: and this diſorder is ſtill further increaſed, by the healthy being not unfrequently chained to the diſeaſed, the dying, and the dead. Dr. Trotter, ſpeaking on the ſame ſubject, gives us an equal melancholy account. When the ſcuttles, ſays he, in the ſhip's ſides, are obliged to be ſhut in bad weather, the gratings are not ſufficient for airing the rooms. He never himſelf could breathe freely below, unleſs immediately under the hatchway. He has ſeen the ſlaves drawing their breath with all that laborious and anxious effort for life, which are obſerved in expiring animals, ſubjected by experiment to foul air, or in the exhauſted receiver of an air-pump. He has alſo ſeen them, when the tarpaulings have been thrown over the gratings, attempting to heave them up, crying out, in their own language, *Kickeraboo, kickeraboo*, that is, “We are dying.” Moſt of them have been recovered, by being brought upon deck; but ſome have periſhed, and this entirely by ſuffocation, as they had no previous ſigns of indiſpoſition.

The ſlaves, after having been ſtowed, ſoon begin to experience the effects that might be naturally expected from their ſituation. The peſtilential breath of many in ſo confined a ſtate renders them ſickly, and the viciſſitude of heat and cold generates a flux. Several die, and others are induced to deſtroy themſelves, or to revenge themſelves on their oppreſſors. The ſhips, having completed the middle paſſage, anchor in their deſtined ports; and the unhappy Africans on board are prepared for ſale. Some are conſigned to brokers, who ſell them for the ſhips. With this view they are examined by labourers, who want them for their farms; and in the ſelection of them, friends and relations are parted without any conſideration; and when they part with mutual embraces, they are ſevered by a laſh. Another mode of ſale is by vendue; in which caſe, they are carried to a tavern, or other public place, where, being put up to ſale, they become the property of the higheſt bidder. Theſe are uſually ſuch as are in a ſick and emaciated ſtate, and are generally ſold for a few dollars. The third mode of ſelling them is by the “ſcramble.” In this caſe, the main and quarter-decks of the ſhip are darkened by ſails, which are hung over them at a convenient height. The ſlaves are then brought out of the hold, and are made to ſtand in the darkened area. The purchaſers, who are furniſhed with long ropes, ruſh, as ſoon as the ſignal is given, within the awning, and endeavour to encircle as many of them as they can.

Theſe ſcrambles, however, are by no means confined to the ſhips. They are made frequently on the ſhore. When the latter happens to be the caſe, the unhappy objects of them are ſhut up in an apartment, or court-yard, the doors of which being thrown open, the purchaſers ruſh in, with their ropes in their hands, as before deſcribed.

Nothing can exceed the terror which the wretched Africans exhibit on theſe occaſions. An univerſal ſhriek is immediately heard. All is conſternation and diſmay. The men tremble. The women cling together in each other's arms. Some of them faint away, and others have been known to expire. If any thing can exceed the horror of ſuch a ſcene, it muſt be the iniquity of valuing a part of the rational creation in ſo debaſed a light, and of ſcrambling for human fleſh and blood.

During the time that elapſes from the ſlaves being put on board, on the African coaſt, to the time when the receivers leave the colonies, after having diſpoſed of their cargoes, about 25,000 lives are deſtroyed, *i. e.* one-fifth, or nearer one-fourth of the number put on board. About 20,000 of thoſe who are annually imported die during the “ſeaſoning;” which ſeaſoning is ſaid to expire, when the firſt two years of ſervitude are completed. This is the time which an African muſt take to be ſo accuſtomed to the colony, as to be able to endure the common labour of a plantation, and to be put into the *gang*. From the period when their ſeaſoning terminates, their ſituation is as follows. They are ſummoned at five in the morning to begin their work. This work may be divided into two kinds, the culture of the

the fields, and the collection of graſs for cattle. The laſt is the moſt laborious and intolerable employment; as the graſs can only be collected blade by blade, and is to be fetched frequently twice a day at a conſiderable diſtance from the plantation. In theſe two occupations they are jointly taken up, with no other intermiſſion than that of taking their ſubſiſtence twice, till nine at night. They then ſeparate for their reſpective huts, when they gather ſticks, prepare their ſupper, and attend their families. This employs them till midnight, when they go to reſt. Such is their daily way of life for rather more than half the year. They are ſixteen hours, including two intervals at meals, in the ſervice of their maſters: they are employed three afterwards in their own neceſſary concerns; five only remain for ſleep, and their day is finiſhed.

During the remaining portion of the year, or the time of crop, the nature, as well as the time, of their employment is conſiderably changed. The whole gang is generally divided into two or three bodies. One of theſe, beſides the ordinary labour of the day, is kept in turn at the mills, that are conſtantly going, during the whole of the night. This is a dreadful encroachment upon their time of reſt, which was before too ſhort to permit them perfectly to refreſh their wearied limbs, and actually reduces their ſleep, as long as this ſeaſon laſts, to about three hours and an half a night, upon a moderate computation. Thoſe who can keep their eyes open during their nightly labour, and are willing to reſiſt the drowſineſs that is continually coming upon them, are preſently worn out; while ſome of thoſe, who are overcome, and who feed the mill between ſleeping and being awake, ſuffer, for thus obeying the calls of nature, by the loſs of a limb; a hand or arm being frequently ground off. In this manner they go on, with little or no reſpite from their work, till the crop ſeaſon is over, when the year (from the time of our firſt deſcription) is completed. They are badly clothed, and very ſcantily fed; and on ſome plantations treated with great ſeverity.

The condition and treatment of the Africans are juſtified by the aſſertion, that they are an inferior link of the chain of nature, and made for ſlavery. Accordingly the inferiority of their capacities has been urged, and alſo their inability for any mental exertions and attainments. But inſtances of genius and of improvement, and of ſkill in the mechanical arts, have been adduced, both among the ancients and moderns, ſufficient to refute this objection. Some have inferred their inferiority in the ſcale of nature, from their colour. We refer thoſe, who wiſh to ſee this argument diſcuſſed, to Mr. Hume's Eſſays, Eſſ. xxi. p. 222, note M; Dr. Beattie's Eſſay on Truth; and Clarkſon's Eſſay, &c.

Sir George Young and captain Thompſon, both of the royal navy, and the reverend Mr. Newton, and ſurgeons Falconbridge and Wilſon, who were ſeverally called upon for their public teſtimony on this ſubject, all declare, that the capacities of the Africans are good; and that they would be equal, under equal advantages, to thoſe of the Europeans.

Mr. Wadſtrom, another of thoſe examined, who travelled on diſcovery in Africa, by order of the king of Sweden, aſſerts the ſame thing; for he ſays, they are as capable of improvement as the whites. He found among them perſons who could manufacture gold and iron. Others made cloth and leather with neatneſs, dyeing the former, and tanning the latter. Others made indigo, ſalt, ſoap, and earthenware, with conſiderable ſkill. He offered to produce different ſpecimens of their work.

This account of their capacity and manufacture is corroborated by captain Wilſon of the royal navy, lieutenant Dalrymple of the army, and Mr. Kiernan, three other witneſſes, all of whom viſited the ſame part of the coaſt.

Of their ſenſibility, ſeveral inſtances occur in the evidence. Mr. Wadſtrom is convinced that they ſurpaſs in affection ſuch of the Europeans as he has known, and that they are honeſt and hoſpitable. He has been among them without fear, though alone, and was always treated by them with civility and kindneſs. Captain Wilſon ſays, that they are grateful and affectionate; that when he was many miles up their country, alone and unprotected, they treated him moſt kindly, vying with each other in entertaining him, and ſhedding tears at his departure. Captain Thomſon, before mentioned, lieutenant Storey of the royal navy, lieutenant Dalrymple, Mr. How, the botaniſt, Mr. Towne, and captain Hall of the merchants' ſervice, concur in deſcribing them as harmleſs, friendly, hoſpitable, juſt and punctual in their dealings, and as capable of virtuous actions as the reſt of mankind. Mr. Bowman, who reſided among them as a trader, found them good and honeſt, friendly and hoſpitable, induſtrious, diſpoſed to trade, raiſing rice for ſale. They ſaid, they ſhould like to trade with good white men, and would ſoon raiſe more plantations of rice. Captain Hills of the royal navy has ſeen them raiſing proviſions, and dreſſing their corn. They appeared to him to poſſeſs great ſenſibility. Several of them ſpoke good French and Engliſh.

This is the character given of them by the witneſſes now mentioned. It is melancholy, however, to obſerve, that as they become acquainted with the European ſlave-traders, their diſpoſition ſeems to be changed; and that they are beſt, where they have the leaſt intercourſe with the latter. Lieutenant Storey tells us, they are more honeſt inland than upon the coaſt. Mr. Towne, who was three or four hundred miles up the country, ſays, the natives are hoſpitable, kind, and ready at learning languages; that in the inland country they are innocent, but, on the coaſt, their intercourſe with Europeans has made them adepts in roguery, and taught them to plunder, and pick up one another to ſell. Dr. Trotter, phyſician, ſays, that they are ſuſceptible of all the ſocial virtues. He has known inſtances of feeling equal to thoſe of any civilized people whatever, and has ſeen no bad habits but among thoſe engaged in trade with white men. Captain Hall found cultivation in the higheſt ſtate at Fernandipo, where they had no trade in ſlaves. Mr. How, the botaniſt, had been upon almoſt every Britiſh ſettlement, and always found the culture in a higher degree, where there was but a little of the ſlave-trade; and juſt the reverſe, where it prevailed. The reverend Mr. Newton ſays, the beſt people were thoſe who had the leaſt intercourſe with the Europeans; and they were worſe, in proportion to their acquaintance with us; and when charged with a crime, would ſay, "Do you think I am a white man?" He lived alone among the Sherbro people in ſafety, who were friendly and civilized. Lieutenant Dalrymple ſtates, that in natural capacity the Africans equal any people whatever. They are humane, hoſpitable, and well diſpoſed. He apprehends, that if they had a proper market for their produce, they would be as induſtrious as any Europeans; for where there was no ſlave-trade, they were very induſtrious, manufacturing cotton-cloth, working in gold, ſilver, and iron, and alſo in wood and leather, making ſaddles, bow-caſes, ſcabbards, and other articles.

It appears from the above account, that the Africans are perſons of the like feelings as ourſelves; that they have the ſame intellectual powers, and the ſame capability of improvement; the ſame ſocial diſpoſitions, and the ſame moral qualifications; but that they are more or leſs innocent,

nocent, as they have more or leſs connection with the Europeans.

To one argument that has been alleged in favour of ſlavery, we wiſh to direct the attention of our readers, before we cloſe this article. It has been ſaid, that ſlavery was not formally aboliſhed by the goſpel, and that it therefore continued for a long time after the introduction of Chriſtianity. It has been ſaid, that St. Paul, having converted Oneſimus to the Chriſtian faith, who was a fugitive ſlave of Philemon, ſent him back to his maſter. This circumſtance has furniſhed the receivers with a plea, that Chriſtianity encourages ſlavery. But they have not only ſtrained the paſſages which they produce in ſupport of their aſſertions, but are ignorant of hiſtorical facts. The benevolent apoſtle, in the letter which he wrote to Philemon, the maſter of Oneſimus, addreſſes him to the following effect: "I ſend him back to you, but not in his former capacity, not now as a ſervant, but above a ſervant, a brother beloved. In this manner I beſeech you to receive him, for though I could enjoin you to do it, yet I had rather it ſhould be a matter of your own will, than of neceſſity."

It appears that the ſame Oneſimus, when he was ſent back, was no longer a ſlave, that he was a miniſter of the goſpel, that he was joined with Tychicus in an eccleſiaſtical commiſſion to the church of the Coloſſians, and was afterwards biſhop of Epheſus. If language, therefore, has any meaning, and if hiſtory has recorded a fact which may be believed, there is no caſe more oppoſite to the doctrine of the receivers, than this which they produce in its ſupport.

It is ſaid again, that Chriſtianity, among the many important precepts which it contains, does not furniſh us with one for the abolition of ſlavery. But the reaſon is obvious. Slavery, at the time of the introduction of the goſpel, was univerſally prevalent, and if Chriſtianity had abruptly declared, that the millions of ſlaves ſhould have been made free, who were then in the world, it would have been univerſally rejected, as containing doctrines that were dangerous, if not deſtructive, to ſociety. In order, therefore, that it might be univerſally received, it never meddled, by any poſitive precept, with the civil inſtitutions of the times: but though it does not expreſsly ſay, that "you ſhall neither buy, nor ſell, nor poſſeſs a ſlave," it is evident that, in its general tenor, it ſufficiently militates againſt the cuſtom.

The firſt doctrine which it inculcates is that of brotherly love. It commands good will towards men. It enjoins us to love our neighbour as ourſelves, and to do unto all men, as we would that they ſhould do unto us. And how can any man fulfil this ſcheme of univerſal benevolence, who reduces an unfortunate perſon, againſt his will, to the moſt inſupportable of all human conditions; who conſiders him as his private property; and treats him, not as a brother, nor as one of the ſame parentage with himſelf, but an animal of the brute creation?

But the moſt important doctrine is that, by which we are aſſured that mankind are to exiſt in a future ſtate, and to give an account of thoſe actions which they have ſeverally done in the fleſh. This ſtrikes at the very root of ſlavery. For how can any man be juſtly called to an account for his actions, whoſe actions are not at his own diſpoſal? This is the caſe with the *proper* ſlave. His liberty is abſolutely bought and appropriated; and if the purchaſe is juſt and equitable, he is under the neceſſity of perpetrating any crime, which the purchaſer may order him to commit; or, in other words, of ceaſing to be accountable for his actions.

Theſe doctrines, therefore, are ſufficient to ſhew, that ſlavery is incompatible with the Chriſtian ſyſtem. The Europeans conſidered them as ſuch, when, at the cloſe of the twelfth century, they reſiſted their hereditary prejudices, and occaſioned its abolition. Hence one, among many other proofs, that Chriſtianity was the production of infinite wiſdom; that though it did not take ſuch expreſs cognizance of the wicked national inſtitutions of the times, as ſhould hinder its reception, it ſhould yet contain ſuch doctrines, as, when it ſhould be fully eſtabliſhed, would be ſufficient for the abolition of them all. See Clarkſon's Eſſay on the Slavery and Commerce of the human Species, paſſim.

SLAVE-TRADE, *Abolition of the.* It is a circumſtance favourable to the hiſtorian, that this great work was never regularly attempted till our own times; becauſe the facts relating to it being freſh in every one's memory, an opportunity has been afforded him of examining them, and of eſtimating their truth: hence poſterity will have the advantage of having more than uſually accurate ſtatements on the ſubject. Mr. Thomas Clarkſon, a gentleman now living, who was among the warmeſt patrons of this ſacred cauſe, has publiſhed an account of the different meaſures purſued to promote it. Theſe were regiſtered at the time, either by himſelf, or the eſtimable committee which acted in concert with him. His hiſtory, in two volumes octavo, has been now more than ſix years before the public, and not the ſhadow of a doubt has been expreſſed as to the authenticity of any thing aſſerted therein; we cannot, therefore, we conceive, hand down information on this great ſubject in a more ſatisfactory manner, than by giving to the reader a conciſe abridgment of the work itſelf.

The great work of the abolition, according to Mr. Clarkſon, was not the entire produce of his own day. It was too mighty to have been accompliſhed, either by a few individuals, or in a ſhort period of time: it was neceſſary that men's minds ſhould have been previouſly inſtructed and prepared: hence, from the very beginning of the infamous traffic, to the time when he became a public actor in the ſcene of its ſuppreſſion, which was in the year 1787, there had not been wanting good men to lift up their voices againſt it: and as the ſentiments of theſe, who were moſt of them authors, had been given to the public in their reſpective works, either in poetry or proſe, for a long ſucceſſion of years, hundreds of perſons had been then taught in England to condemn it. Theſe, that is, the good men juſt alluded to, Mr. Clarkſon conſiders as ſo many neceſſary forerunners (indeed he gives them that title); and conſiders them alſo, though moſt of them lived before his own time, as ſo many coadjutors in the work. The firſt mentioned are cardinal Ximenes, the emperor Charles V., pope Leo X., queen Elizabeth of England, and Louis XIII. of France; concerning all of whom he gives anecdotes in ſupport of the title thus given them.

Having ſpoken firſt of the men in power, Mr. Clarkſon divides the forerunners who walked in humbler life into four claſſes. The firſt conſiſts principally of perſons in England, of various religious deſcriptions, who bore their teſtimony againſt the trade in their ſucceſſive writings up to the year 1787. Among the poets were Pope, Thomſon, Shenſtone, and Cowper; among the divines, biſhop Warburton, Rd. Baxter, Beattie, Weſley, Whitfield, Wakefield, and Paley; among the others, were Monteſquieu, Hutchinſon, Wallis, Burke, Poſtlethwaite, Day, Hartley, Millar, and Granville Sharp. The latter, however, is to be particularly diſtinguiſhed from the reſt, and alſo to be borne in mind; for whereas the others had only handed down the traffic in queſtion as infamous, by the mention made of it in their reſpective works, this good man ſpent whole years in bringing the cruelty and wickedneſs of it into public notice. He tried, at his own expence, the famous caſe of Somerſet, and ſeveral others, in our courts of law. He was, in fact, the firſt labourer in the cauſe. He began to be the public advocate of the oppreſſed Africans in 1765, and was waiting for opportunities for farther exertion in 1787, the particular epoch before-mentioned.

The ſecond claſs conſiſts of the Quakers in England. This eſtimable ſociety paſſed a public cenſure upon the traffic at their yearly meeting in London, in 1727. This they followed up, by other reſolutions as a body, in 1758, 1761, 1763, and 1772, when they had become principalled againſt it as againſt a crime of the deepeſt dye. In 1783 they petitioned parliament againſt its continuance. In this year certain members of the ſociety thought it their duty to make their fellow countrymen at large acquainted with the horrible nature of it: theſe were, Thomas Knowles, George Harriſon, Samuel Hoare, John Lloyd, Joſeph Woods, and William Dillwyn. They formed themſelves into a committee in London for this purpoſe; they wrote and circulated books; they conveyed alſo information on the ſubject through the London and country newſpapers. It was not known, however, from whom the information came, as their names were concealed from the public. In this manner they continued to work their way from 1783 to 1787.

The third claſs conſiſts of the Quakers and others in North America. The Quakers there entertained the ſame opinion as their brethren in England on this ſubject. In 1696 and in 1711, they condemned, as a religious body, this cruel traffic; and in 1754, 1755, 1774, 1776, and 1778, they not only paſſed reſolutions againſt it, as far as their own members were concerned, but alſo againſt ſlavery itſelf. In proceſs of time, however, individuals roſe up out of this benevolent body, and became public labourers in the cauſe of the unhappy Africans. The two principal of theſe were John Woolman and Anthony Benezet. The former travelled many hundred miles on foot, to converſe with planters, and others, on the iniquity of holding their fellow creatures in bondage; and the latter laboured for years in collecting information concerning Africa and the ſlave-trade, and in handing it to the world. At this time other people, of other religious denominations, came forward in North America, and contributed to increaſe the odium which the Quakers had been the firſt to excite there againſt the traffic; when, in 1774, James Pemberton, a pious Quaker in Pennſylvania, and Dr. Ruſh, an eminent phyſician, and a man of weight among the Preſbyterians in the ſame province, formed a committee, in which perſons of different religious ſects joined for the purpoſe of aboliſhing both the ſlave-trade and ſlavery on their own continent. This committee was obliged to ſuſpend its operations during the war with Great Britain, but afterwards reſumed its functions. In 1787 it added conſiderably to its numbers, and took in, among others, the celebrated Dr. Franklin, who was its firſt preſident in its renovated ſtate.

It will be proper to ſtop here, and to interrupt the thread of the hiſtory for a moment. It has appeared, from what has been ſaid above, firſt, that Mr. Granville Sharp, the moſt conſpicuous member of the firſt of the claſſes now mentioned, was alive in 1787, and then waiting for an opportunity of exerting himſelf farther in behalf of the injured Africans; ſecondly, that of the ſecond claſs, William Dillwyn was one of a committee for the ſame object in the ſame year; and, thirdly, that James Pemberton was alſo alive in the very ſame year, and a very conſpicuous member of the third. Now it happened that William Dillwyn, who had been born and long reſident in America, had been in habits of intimate friendſhip with James Pemberton; and that in conſequence of his acquaintance alſo with the venerable Anthony Benezet, he had been introduced, by means of a letter from him, upon coming to England, to Mr. Granville Sharp. Here then we find that a member of the ſecond claſs was accidentally known to a member of the firſt, and alſo to a member of the third: thus we ſee how eaſily William Dillwyn might be made the medium through whom the members of all the claſſes might be eaſily united, if a fit occaſion ſhould offer.

To return, we come now to the fourth claſs of forerunners. The firſt in this claſs was Dr. Peckard, maſter of Magdalen college, in the univerſity of Cambridge. This gentleman had not only cenſured the ſlave-trade in the ſevereſt manner, in a ſermon preached before the univerſity itſelf; but when he became vice-chancellor of it, in 1785, he gave out the following ſubject for one of the bachelors' prizes, "Anne liceat invitos in ſervitutem dare?" or, "Is it right to make ſlaves of others againſt their will?" At this time Mr. Thomas Clarkſon, before-mentioned, who had obtained the bachelor's prize of the former year, determined to become a candidate for that of the preſent. He took prodigious pains to make himſelf maſter of the ſubject, as far as the time would allow, both by procuring proper books, and by ſeeing as many perſons as he could of thoſe who had been in Africa, and who had become in any degree acquainted with the nature of the ſlave-trade. Having thus gained a conſiderable ſtock of neceſſary information, he wrote his Latin eſſay, and having ſent it in to the vice-chancellor, he ſoon found himſelf honoured with the firſt prize. After this, being then in London, he went down to Cambridge at the time of the commencement, in order to read it publicly, as is uſual, in the ſenate-houſe. The next day he returned towards London: he was then on horſeback; but while upon the road the ſubject of the eſſay entirely engroſſed his thoughts; he became at times ſeriouſly affected as he travelled on. He once ſtopped his horſe, and diſmounted and ſat down on a bank by the roadſide. Here he tried to perſuade himſelf, that the contents of the eſſay which he had read in the ſenate-houſe the day before, were not true. The more, however, he reflected upon the authorities on which he knew them to be founded, the more he gave them credit; and the more he gave them credit, the more he was convinced that it was an imperious duty in ſome one to endeavour to ſee the ſufferings of the unhappy Africans to an end. Agitated in this manner, he reached London. This was in the ſummer of 1785. In the autumn of the ſame year, he found himſelf often ſimilarly exerciſed; till at length he began to have ſerious thoughts of devoting his life to the cauſe of injured Africa. Being then but twenty-four years of age, he conſidered his youth and his want of knowledge of the world as a great obſtacle. Many other circumſtances occurred to diſcourage him. He thought, however, that there was one way, in which he might begin to be uſeful to the cauſe; namely, by tranſlating his Latin eſſay, and publiſhing it in Engliſh. Accordingly he began the work, and having finiſhed it, he was looking out for a publiſher, when he accidentally met an old friend of his family, who belonged to the religious ſociety of the Quakers. This gentleman, of his own accord, aſked him why he had not publiſhed his prize eſſay in Engliſh. Many of his brethren (the Quakers), he ſaid, were anxiouſly expecting it. Upon farther converſation, this gentleman introduced Mr. Clarkſon to Mr. Phillips, a bookſeller in George-yard, Lombard-ſtreet, and who was alſo of the religious ſociety before-mentioned; at which interview it was agreed that the latter ſhould immediately publiſh the work. In a ſhort time after this, Mr. Phillips introduced Mr. Clarkſon to Mr. Dillwyn of Walthamſtow, one of the ſecond claſs of coadjutors before-mentioned, with whom he ſpent the day. Here it was that he heard for the firſt time of the labours of Mr. Granville Sharp. But how ſurpriſed was he to learn that Mr. Dillwyn had two years before aſſociated himſelf with five others (as has been already mentioned), for the purpoſe of enlightening the public mind in England on this great ſubject. How aſtoniſhed was he to find that a ſociety had been formed in North America for the ſame purpoſe, with ſome of the principal of which Mr. Dillwyn was himſelf acquainted. He was almoſt overwhelmed with the thoughts, which darted upon him on this occaſion. He could not but conſider that he had been providentially led to Mr. Dillwyn's houſe; that the day-ſtar of African liberty was riſing; and that probably he himſelf might be now permitted to have the honour of becoming an humble inſtrument in promoting it. Soon after this he was introduced to the venerable Mr. Sharp, the laſt and moſt eminent of the ſecond claſs of coadjutors, and ſoon after this his work came out under the title of "An Eſſay on the Slavery and Commerce of the human Species, particularly the African, which was honoured with the firſt Prize in the Univerſity of Cambridge, for the Year 1785." The work having been now uſhered into the world, (this was in June 1786,) Mr. Clarkſon reſolved upon the diſtribution of it in the moſt ſelect manner he could, in order that the caſe of the unhappy Africans might be known by thoſe who had in ſome degree the power of relieving them. Accordingly, at his requeſt, Dr. Baker, a moſt exemplary clergyman in London, lord and lady Scarſdale, ſir Charles and lady Middleton, and Mr. Bennet Langton, the intimate friend of Dr. Johnſon, of Jonas Hanway, of ſir Joſhua Reynolds, of Edmund Burke, and of other celebrated perſons, undertook to diſtribute copies of it perſonally among their own friends, in the higher ranks of life, and to uſe their intereſt in procuring a peruſal of them. Under their auſpices the book was firſt introduced into the polite world. The mind, however, of the author became daily more and more agitated on the ſubject of it. He was not ſatisfied that what he was then doing was all that was neceſſary to be done; or that it was all that was required of him. To make the caſe of the unhappy Africans known, was deſirable as a firſt ſtep; but would this of itſelf put a ſtop to the horrors of the trade? He believed not: he believed there would be no hope of ſucceſs, unleſs ſome one would reſolve to make it the buſineſs of his life. The queſtion then was, was he himſelf called upon to do it? His own peace of mind required that he ſhould give a final anſwer to this queſtion. To do this he retired frequently into ſolitude. The reſult was, after the moſt mature deliberation, and the moſt painful ſtruggle, that he determined to devote his whole life, ſhould it be neceſſary, to the cauſe. This determination was made about the latter end of December, 1786; in the beginning of 1787 the diſtribution of the eſſay went on, but by additional hands. Mr. Sheldon, ſir Herbert Mackworth, lord Balgonie (now lord Leven), each took a part on the occaſion. The Quakers joined in the diſtribution alſo, among whom, Mr. Richard Phillips (now living) is to be particularly noticed. This arrangement having been made, Mr. Clarkſon was now able to devote all his time to qualify himſelf for the arduous ſituation to which he had devoted himſelf. He gained introductions to perſons who had been in Africa and the Weſt Indies, and obtained ſtill farther information on the ſubject in its different branches. He viſited ſlave-ſhips lying in the Thames, either as they came in or ſailed out of port, that he might know their conſtruction and other particulars. He went frequently to the cuſtom-houſe in London, where he learnt the nature of the articles which conſtituted the traffic, the loſs of ſeamen employed in it, and other matters which he found it eſſential to know. He kept up a correſpondence with perſons in Liverpool for the ſame purpoſe. He viſited alſo members of parliament, and this almoſt daily, to intereſt them in his cauſe; to give them information; to anſwer queſtions; and to explain doubts, if they had any, on any part of the ſubject. Among thoſe who appeared moſt affected by his viſits, and moſt anxious to co-operate with him, was Mr. Wilberforce, the member for the county of York. This gentleman not only read the evidence which Mr. Clarkſon ſent him on the ſubject, as he collected it freſh from day to day, but actually ſent for, and took the pains to examine, at his own houſe, thoſe perſons who had given it, that he might judge for himſelf, from their own mouths, of the truth or falſehood of the enormities which had been charged upon the ſlave-trade. The ſame gentleman appointed alſo a meeting once a week, at his own houſe, of a few ſelect friends, to deliberate on the propriety, and, if this were reſolved upon, on the proper method of taking up the cauſe. Theſe meetings continued for ſome time, when at length, at a dinner at the houſe of Mr. Bennet Langton, who has been before-mentioned, where ſeveral perſons of conſequence were invited for the purpoſe of talking over the matter, and of coming to a final determination upon it, Mr. Wilberforce pledged himſelf to bring forward the great queſtion of the abolition of the ſlave-trade in parliament, as ſoon as ever he ſhould feel himſelf prepared for ſo tremendous a taſk. Here then the matter began to aſſume a ſhape. A parliamentary leader had been ſecured, and one whoſe virtuous life correſponded with the ſacredneſs of the cauſe which he was to advocate. Mr. Clarkſon, who was preſent at this dinner, carried directly the news of what had taken place to ſeveral of his friends, but particularly to Mr. Granville Sharp, Mr. Dillwyn, and three or four others of the religious ſociety of the Quakers, all of whom he had previouſly taught to expect ſuch a reſult. The conſequence was, that the following perſons met the next day, and without loſs of time formed themſelves into a committee, "for procuring ſuch information and evidence, and publiſhing the ſame, as may tend to the abolition of the ſlave-trade, and for directing the application of ſuch monies as may be collected for the above purpoſe," *viz.* Granville Sharp, Samuel Hoare, George Harriſon, John Lloyd, Joſeph Woods, William Dillwyn, Thomas Clarkſon, Richard Phillips, James Phillips, Philip Sanſom, John Barton, and Joſeph Hooper. Mr. Granville Sharp, the firſt mentioned, may be conſidered, from what has been before ſaid, as repreſenting the firſt of the claſſes which have been deſcribed. The four next were the real repreſentatives of the ſecond. The third claſs, or that of the Quakers in America, may be conſidered as repreſented in the perſon of William Dillwyn, by whom, indeed, it was afterwards united to the committee now formed; and Mr. Clarkſon and Mr. R. Phillips as repreſenting the fourth, moſt of the members of which they had been the means of raiſing. "Thus," ſays the hiſtorian, "on the 22d of May, 1787, the repreſentatives of all the four claſſes, of which I have been giving a hiſtory from the year 1516, met together, and were united in that committee, to which I have been all along directing the attention of the reader; a committee, which, labouring afterwards with Mr. Wilberforce as a parliamentary head, did, under Providence, in the ſpace of twenty years, contribute to put an end to a trade, which, meaſuring its magnitude by its crimes and ſufferings, was the greateſt practical evil that ever afflicted the human race. After the formation of the committee, notice was ſent to Mr. Wilberforce of the event; and a friendſhip began, which has continued uninterruptedly between them from that to the preſent day." In the following month, that is, in June 1787, the committee ſimplified its former title, and was uſhered into the world. It profeſſed to have nothing to do with the emancipation of ſlaves already in bondage. Its only object was the abolition of the African ſlave-trade. From this period we ſhall give a hiſtory of its proceedings, year by year.

The committee was no ſooner formed, than Mr. Clarkſon drew up "A Summary View of the Slave-Trade, and of the probable Conſequences of its Abolition." It conſiſted only of about a dozen pages. It detailed the different methods of making ſlaves in Africa, their treatment, ſufferings, and mortality in the paſſage; and alſo the treatment of the ſurvivors in the colonies to which they were carried; and it promiſed the publication of an Eſſay on the Impolicy of the Slave-trade. This ſummary the committee determined to print, and to circulate all over the kingdom. In the mean time Mr. Clarkſon was to take a journey to the different ſlave-ports, to increaſe his own knowledge of the ſubject. Such knowledge was abſolutely neceſſary in caſe parliament ſhould call for evidence: and if there was any one time more fit than another for procuring ſuch evidence, it was the preſent; for men's minds had not then been heated by talking upon the ſubject, nor had intereſt hitherto felt itſelf biaſſed to conceal the truth; but as ſoon as ever it ſhould get abroad that parliament was to look into the ſubject, all avenues to farther information would be ſhut againſt him. The firſt place he viſited was Briſtol, where he reſided for ſome weeks. Here he obtained a knowledge of ſeveral articles of African produce, ſuch as rice, indigo, cotton, ſpices, and woods, and collected ſpecimens of them. He obtained ſpecimens alſo of the different manufactures of the natives of Africa, both in wood, cotton, leather, iron, and gold. He examined the conſtruction of ſlave-ſhips, and took the dimenſions of ſeveral. He obtained hiſtories of their former voyages. He collected chains, handcuffs, thumbſcrews, and other horrid inſtruments uſed in this execrable traffic. He diſcovered the ſcandalous modes of procuring and paying thoſe ſeamen who were employed in it, the ſad ratio of their mortality on the voyage, and the prodigious difference between the mortality of theſe and of thoſe employed in other trades, of which he was enabled to take a comprehenſive view, from procuring the muſter-rolls of almoſt every ſhip belonging to the port. But that which hurt his feelings the moſt, and which kept him indeed in a ſtate of conſtant miſery while in Briſtol, was the barbarous uſage, and this almoſt without an exception, of the ſeamen employed in this traffic. He took many out of the ſlave-veſſels there. He took up the cauſe of ſome of theſe, and obtained damages for them in the courts of law. He ſent a chief mate to priſon for the murder of one of the crew acting under him. While at Briſtol, he formed a committee to act in union with that of London, and obtained promiſes of petitions to parliament againſt the continuance of the inhuman traffic from that city, and from Bath, Monmouth, and Bridgewater. On his journey from Briſtol to Liverpool, he procured the promiſe of ſimilar petitions from Glouceſter, Worceſter, and Cheſter, and ſecured the provincial newſpapers as he travelled on in behalf of his cauſe. On his arrival at Liverpool, he followed the ſame line of enquiry as at Briſtol, for ſix weeks, after which period (ſo incenſed were merchants, captains of ſhips, and others connected with the trade, againſt him) it would have been dangerous to ſtay. From thence he viſited Lancaſter, the laſt of the ſlave-ports, and at length returned to London, after an abſence of five months, in the December of 1787. The committee, in the mean while, that is, during his abſence, had been equally well employed, and had been equally indefatigable. The firſt thing they did was to make known, by public advertiſement, their exiſtence as a committee, and the great object they had in view. They ordered a ſeal to be engraved for their correſpondence. The device upon it was a negro in chains, kneeling, and in a ſupplicating manner lifting up his hands to heaven. The motto round the device conſiſted of theſe words, "Am I not a man and a brother?" They then added to their committee, to increaſe their labourers; and having done ſo, they directly opened a correſpondence throughout England, Wales, and Scotland, which they extended afterwards to America. This gave them an opportunity of making their cauſe known in the moſt extenſive manner. Accordingly, when things had been thus prepared, they circulated many thouſands of the ſummary views before-mentioned, and, at the ſame time, addreſſed by letter all the corporate bodies in the kingdom. Theſe efforts ſoon convinced them, that there were thouſands of kindred ſouls in their own country, who felt with them on the great ſubject of their inſtitution. The Quakers were the firſt, as a body, to acknowledge and approve it; the general Baptiſts the next: then followed letters of approbation, and promiſes of ſupport from people of all religious denominations. Among theſe were, the famous Dr. Price and John Weſley; Mr. Roſcoe, the hiſtorian and poet; Dr. Porteus, biſhop of Cheſter; Dr. Woodward, biſhop of Cloyne; Dr. Hinchliffe, biſhop of Peterborough; Dr. Horne, afterwards biſhop of Norwich; Dr. Bathurſt, now biſhop of the ſame; archdeacons Paley and Plymley (now Corbett); the celebrated marquis de la Fayette, now alive, who was ſoon afterwards conſpicuous in the French revolution; and Briſſot and Claviere, afterwards two diſtinguiſhed members of the national convention in France, and who ſuffered under the tyranny of Robeſpierre. This good feeling continued to ſpread, when, in the month of February, 1788, there appeared to be among the people of England a general feeling in behalf of the injured Africans. By this time thirty-five petitions had been preſented to parliament from different places, praying for the abolition of the ſlave-trade, and ſeveral others had been reſolved upon. Theſe proceedings produced ſuch an effect upon the government, that the king was adviſed to order a committee of privy-council to inquire into the nature of the ſlave-trade. This order was dated February 11. An inquiry was of courſe immediately ſet on foot. The firſt witneſſes examined, were perſons ſent expreſsly as delegates from Liverpool, who had not only been themſelves in the trade, but who were then intereſted in its continuance. Theſe endeavoured to ſhew, that none of the enormities with which it had been charged belonged to it; and that it was even attended with circumſtances favourable to the unhappy victims of it. A great prejudice therefore was excited, in the very beginning of the inquiry, in the minds of ſome of the privy-council againſt the abolitioniſts; whom they conſidered as miſinforming the public mind with reſpect to a traffic, which appeared to be ſo vitally connected with the manufacturing and commercial intereſts of the country, that it would be almoſt national ruin to aboliſh it. Happy was it for the cauſe, at this moment, that Mr. Clarkſon had taken his journey to Briſtol and other places, as before-mentioned; for he had become acquainted, in the courſe of it, with perſons who had witneſſed the horrors of the trade; but who, having then quitted it, had no intereſt in concealing the truth. Theſe, though few, were highly reſpectable; and their evidence, when called before the council, contributed to counteract that of the Liverpool delegates, and others, and to turn the tide, which had run ſo ſtrong againſt the abolitioniſts, in their favour. The inquiry which had been thus ſet on foot, continued through February, March, April, and a part of May. During this time the petitions from the people to parliament had increaſed to one hundred and three. The committee alſo had circulated many new books throughout the kingdom, written by eye-witneſſes of the ſeveral facts they contained, and all contributing to give new information, and to add new horror to the trade. Mr. Wilberforce alſo had been preparing to introduce the ſubject into parliament; but at the time when his motion was expected, he was too ill to make it. Indeed his life was deſpaired of. Under theſe circumſtances, his friend, Mr. Pitt, then chancellor of the exchequer and prime miniſter, undertook to ſupply his place. On the 9th of May he opened the buſineſs in the houſe of commons, and concluded by a motion, "that this houſe will, early in the next ſeſſion of parliament, proceed to take into conſideration the circumſtances of the ſlave-trade complained of in the petitions, and what may be fit to be done thereupon." A diſcuſſion took place in conſequence, during which there was an apparent enthuſiaſm in the houſe in behalf of the injured Africans. The members for Liverpool, however, denied the exiſtence of any of the cruelties complained of; but they did not oppoſe the motion, and therefore it was unanimouſly agreed to. This pledge having been given by parliament, the public ſeemed ſatisfied with it, and of courſe nothing more was expected in that ſeſſion; when, on the 21ſt of May, ſir William Dolben ſuddenly roſe up in the houſe of commons, and moved for leave to bring in a bill on the ſubject of the ſlave-trade. As the trade, he ſaid, was evidently allowed to go on till the next ſeſſion, he thought it was the duty of the houſe to take care that it ſhould be carried on with as much humanity as poſſible in the interim. His great object, therefore, was to alleviate the ſufferings of the poor Africans in their tranſportation, by allowing them more room, which might be done by regulating the number to be carried by the tonnage of the veſſel. Leave was accordingly given; but the merchants of Liverpool determined to oppoſe the bill in every ſtage. They diſpatched immediately to London thoſe very perſons to be examined before the houſe, whom they had before ſent for examination to the privy-council. When counſel had cloſed their caſe, a debate enſued, in which the ſtatements of theſe witneſſes were expoſed, greatly to their mortification, and the bill paſſed by a majority of fifty-five to five. It was then carried to the lords. Here a ſtill more determined oppoſition was begun, and carried on in ſuch a manner, and with ſo much apparent ſucceſs (the houſe being very thin at that ſeaſon), as to alarm the abolitioniſts, not only for the fate of the bill itſelf, but for that of their great queſtion the enſuing year. At length it paſſed the upper houſe, as through an ordeal of fire, and received the king's aſſent, on July 11. During all this time, the privy-council continued their examinations. Mr. Clarkſon underwent an examination among others. It was at this time that he brought out his powerful eſſay on the impolicy of the ſlave-trade. This was circulated in great numbers by the committee, upon whom too much praiſe cannot be beſtowed for their labours. From July 1787 to July 1788, the time we are now come to, they had held fifty-one long committees: they had held as many more ſub-committees: they had diſtributed (beſides 26,526 reports, debates in parliament, and other matters) 51,432 pamphlets or books. They had rouſed the feelings of the whole Engliſh nation, and had attracted the notice of ſome of the moſt diſtinguiſhed perſons in France and Germany.

The ſeſſion of 1788 was no ſooner over, than Mr. Clarkſon undertook a journey to all the ſea-ports of the kingdom lying between Kent and Cornwall. His object was to find out, if poſſible, new witneſſes to ſtrengthen the good cauſe. He met with conſiderable ſucceſs in his journey, and he formed committees, auxiliary to that of London, as he went along. On his return to London he was again examined by the privy-council, to whom he ſhewed, by way of evidence, his collection of African curioſities, conſiſting of produce and manufactures, which he had now completed. He introduced alſo to their lordſhips, for examination, all the new witneſſes he had diſcovered, and whoſe teſtimony was of the higheſt value. The committee, in the mean time, had been indefatigable. They had directed their correſpondence to new parts of the kingdom, as well as of North America. They had addreſſed the rulers of Spain, Portugal, and Sweden, in behalf of their inſtitution, and had opened a communication with Germany on the ſame ſubject. They had printed and circulated no leſs than five new works to promote their cauſe, and, beſides, that famous engraving of the ſection of the ſlave-ſhip (where the bodies of the negroes were ſeen packed in the different parts of it), which afterwards excited ſuch univerſal ſympathy in the country, and which cauſed ſuch an univerſal abhorrence of the trade. About this time, that is, on the 19th of March, 1789, Mr. Wilberforce, who was then but juſt recovered from his long and ſevere illneſs, moved in the commons, that the houſe ſhould on Thurſday, the 29th of April, take into conſideration its own reſolution of the laſt ſeſſion. This motion was agreed to, but it became immediately the ſignal to all thoſe who ſuppoſed themſelves intereſted in the continuance of the trade, ſuch as planters, mortgagees, merchants, manufacturers, and others, to begin a tremendous oppoſition. Meetings were called, and frightful reſolutions entered into. The public papers were filled with them. Here, as well as in pamphlets, the moſt bitter invectives were poured forth againſt the abolitioniſts. Emancipation was induſtriouſly confounded with abolition. Compenſation was demanded to a moſt monſtrous degree. The cry, indeed, was ſuch, that many began to be ſtaggered about the propriety of the total abolition of the trade. At this time Mr. Pitt, his majeſty's chancellor of the exchequer, laid the privy-council report, conſiſting of the examinations before-mentioned, which came out in the ſhape of a large folio volume in print, upon the table of the houſe of commons, and moved, in order that members might have time to become acquainted with the evidence it contained, that the conſideration of the ſlave-trade, which ſtood, by Mr. Wilberforce's motion, for the 29th of April, ſhould be poſtponed to the 12th of May. This was agreed to. On the day appointed, Mr. Wilberforce roſe, and in a ſpeech of three hours and a half, introduced the great queſtion into parliament. He reaſoned entirely from the evidence contained in the report juſt mentioned, and deduced from it twelve grand propoſitions, which he read, and then laid them upon the table. Theſe propoſitions contained the whole queſtion. He wiſhed them to be argued at a future day. Upon this, great oppoſition was manifeſted by the members for Liverpool and others, and a warm debate took place, when it was agreed that they ſhould be taken into conſideration on the 21ſt of May. When the day arrived, ſeveral petitions were preſented to the houſe, by perſons intereſted in the traffic, againſt its abolition. Mr. Wilberforce roſe up and addreſſed the houſe. After this, an altercation took place rather than a debate, in which much heat and animoſity were manifeſted. Thoſe members who eſpouſed the cauſe of the intereſted perſons, ſeeing that it would be overthrown, if they judged of the merits of it by the privy-council report, would not now abide by the latter, but rejected it as an imperfect ſort of evidence, and demanded that witneſſes ſhould be heard at the bar of the houſe of commons in explanation of many of the mis-ſtatements which that book contained. By theſe means they endeavoured to get rid of the propoſitions altogether. Their demand, however, after a good deal of contention, was complied with, and on the 26th of May counſel were heard, and one witneſs, a ſlave-captain, was examined. Their object now was to interpoſe every legal ſpecies of delay, and in this they ſucceeded ſo well, that from the 26th of May to the 9th of June, only two of their witneſſes had been examined. In this ſlow way they went on till the 23d of the ſame month, when it was ſeen that it would be utterly impoſſible to bring the queſtion to a final deciſion in that ſeſſion, for they declared that they had many evidences yet to produce, and that they muſt and would be heard. Accordingly they moved, and Mr. Wilberforce agreed, that the farther conſideration of the ſubject ſhould be poſtponed to the next ſeſſions.

As thoſe who were intereſted in the continuance of the trade had now got rid of the privy-council report, and had introduced new evidences to the commons in behalf of their caſe, it became the committee to collect as reſpectable a body of witneſſes as poſſible on their own ſide of the queſtion. Mr. Clarkſon had undertaken to traverſe the kingdom again for this purpoſe, and had ſet out, when, hearing that the French revolution had broken out, and that a committee for the abolition of the ſlave-trade had been formed in Paris, he returned, and immediately haſtened to the latter city, where he arrived at the latter end of July. He ſoon became acquainted with the marquis de la Fayette, monſieur Necker, the duke de la Rochefoucauld, the marquis de Condorcet, and Meſſrs. Mirabeau, Petion, Briſſot, Claviere, and other diſtinguiſhed perſons. He ſpent his time, while in Paris, in attending the committee there, in viſiting members of the National Aſſembly, and in the perſonal diſtribution of books among them, but particularly his "Eſſay on the Impolicy of the Slave-Trade," which he had cauſed to be tranſlated into French for that purpoſe. Returning to London in January 1790, he found that Mr. Wilberforce had carried a motion in the commons, that witneſſes ſhould not be examined in future at the bar of that houſe, but in a committee-room, which ſhould be open to all members. This was neceſſary for the ſake of diſpatch, as the examinations otherwiſe might have taken up ten years. Mr. Clarkſon now reſumed the journey which he had begun in the preceding ſummer, in ſearch of new and reſpectable witneſſes. He made a tour of 1200 miles in three weeks, during which he found out ſixteen perſons capable of giving good teſtimony on the ſubject, but could only prevail upon three to be examined. On his return to London, he found that the examinations of witneſſes in behalf of thoſe intereſted were going on in the committee of the houſe of commons, and with ſo much rapidity, that it was expected their caſe would be ſoon cloſed. This alarmed him exceedingly; for out of ſeventeen perſons who ſtood upon his liſt as having promiſed to give their teſtimony in behalf of the abolition, one had lately died, and no leſs than eight, being ſeafaring perſons, were then out of the kingdom. He determined, therefore, upon another journey; and on turning the ſubject over in his mind, he thought he ſhould obtain the greateſt number of diſintereſted witneſſes in the ſhorteſt poſſible time, if he could go on board all the ſhips of war lying in ordinary at the king's ports in different parts of the kingdom. Impreſſed with this idea, he went to Deptford, and firſt boarded all the men of war that were lying there. He then proceeded to Woolwich, and afterwards to Chatham, Sheerneſs, Portſmouth, and Plymouth, where he boarded others in like manner, to the number altogether of four hundred, in which he picked up ſeveral very excellent and important witneſſes. On the 20th of April, the perſons intereſted had juſt cloſed their caſe. Accordingly Mr. Wilberforce moved, on the 23d of the ſame month, in the houſe of commons, that witneſſes ſhould be heard in behalf of the abolition. Upon this much clamour enſued. The members, who acted in union with the perſons intereſted in the continuance of the ſlave-trade, wiſhed to have the caſe directly argued, that is, upon their own evidence, and without hearing any on the other ſide, and reſiſted accordingly. Their oppoſition, however, proved ineffectual againſt the eloquence of Mr. Wilberforce, ſupported powerfully as he was by that of Mr. Pitt and Mr. Fox. At length, the witneſſes in behalf of the abolition took poſſeſſion of the ground which the others had left, and no leſs than twenty-four, ſome of whom had been found out ſince the laſt tour, were examined before the cloſe of the ſeſſion. At this time it is very curious to remark, that the feelings of parliament, and thoſe of the people, were very different on this great queſtion. The tide certainly ran againſt the abolitioniſts in the houſe of commons. The old hue and cry had been revived of intended emancipation under the pretence of abolition; of monſtrous indemnification to the planters; and of the certain maſſacre of the whites by the negroes, if the trade were to be aboliſhed, but in more furious language, and to a greater extent than before. The feeling, on the other hand, in the country, was warmly on the ſide of the abolition. It had been kept up and increaſed by various circumſtances. The committee had been daily employed in anſwering, through the medium of the public papers, every objection which had been ſtarted as hoſtile to their cauſe. They had alſo by this time diſtributed all over England, Scotland, and Wales, the horrible and affecting engraving of the ſection of the ſlave-ſhip before-mentioned. Individuals, too, had kept alive the popular feeling in various ways. Wedgewood, the celebrated manufacturer, had taken the committee's ſeal, as before explained, for a model, and had ſtruck off and diſtributed many thouſand ſmall cameos in plaſter. The ground of each of theſe cameos was white, but the negroe, who was ſeen imploring compaſſion on his knees in the middle of it, was of his own native colour. Cowper alſo, and other poets, had written beautiful and affecting ſongs on the ſubject. Theſe were circulated very copiouſly through the kingdom, and ſome of them were ſung in the very ſtreets.

Not more than half the evidence, which was deemed neceſſary, having been heard on the ſide of the abolition in the ſeſſion juſt paſſed, it became an imperious duty in the committee to uſe every poſſible exertion to complete it, and this in the beſt poſſible manner, before the next. Such exertion was abſolutely eſſential to victory. Mr. Clarkſon was, therefore, again ſolicited to traverſe the kingdom for this purpoſe. This journey being of the utmoſt importance, Mr. Wilberforce prepared an ingenious liſt of queſtions to aſſiſt him in his examinations and inquiries. With this he departed, and travelled from Auguſt 1790, to February 1791, during which time he went over the greateſt part of the iſland, and had the good fortune to add a conſiderable number of new and important witneſſes to his liſt. At length the examinations were reſumed in the committee of the houſe of commons, and they were cloſed finally on the 4th of April. No leſs than ſixty-nine perſons had given their teſtimony in this and the preceding ſeſſion in behalf of the abolition of the ſlave-trade. The evidence having been printed on both ſides for the uſe of the members, as the baſis upon which to argue the caſe, the 18th of April was fixed upon as the day for deciding it. By this time every effort had been made by the perſons intereſted to render the queſtion unpopular in the commons. Emancipation, indemnification, maſſacre, ruin, had been vociferated over and over again in the ears of the members there. At this time, unhappily the moſt ſanguinary ſcenes were taking place in St. Domingo, in conſequence of the revolution which had been effected there, and an inſurrection had broken out in the Britiſh iſland of Dominica. All theſe had been induſtriouſly detailed in print, but with great exaggeration, and added to the cries juſt mentioned. This union of reports and cries had produced ſuch a terrific effect upon many members, that they conſidered the abolitioniſts, by perſevering in their queſtion, as ferocious monſters; and in this unfavourable frame of mind they went into the houſe on the day fixed for the diſcuſſion, to diſcharge their duty with reſpect to this great queſtion. On this day, namely, the 18th of April, 1791, Mr. Wilberforce made a moſt luminous and affecting ſpeech, in which he took a moſt maſterly view of the whole queſtion in all its different departments, as it related both to Africa and the Weſt Indies. He argued the inhumanity of the traffic; he argued its impolicy; he appealed to feeling; he appealed to reaſon; he tried to diſarm his opponents by candour; he exhorted them to attend to their own intereſt; and concluded by moving for leave to bring in a bill to prevent the farther importation of ſlaves into the Britiſh colonies in the Weſt Indies. After this, a moſt ſerious diſcuſſion enſued, which laſted till three in the morning, when ſeveral members, being yet deſirous of ſpeaking, the buſineſs was adjourned to the next day. It was then argued again till half paſt three in the morning, when the houſe divided on the original motion. There were for it but 88 votes, and againſt it 163; ſo that this great cauſe of humanity, juſtice, and religion, which had coſt ſo many years of labour, was loſt by a majority of 75 votes. Upon the news of this ſignal defeat, the committee for the abolition of the ſlave-trade held a meeting, which was conducted with the moſt ſolemn dignity. They voted thanks to the illuſtrious minority which had lately ſtood forth the aſſertors of Britiſh juſtice and humanity, and the enemies of a traffic in the blood of man; and entered into ſeveral reſolutions, the ſubſtance of one of which was, that they conſidered the late deciſion of the houſe rather as a delay than a defeat; that they did not deſpair of final ſucceſs; and that they would never deſiſt from appealing to their countrymen, till the commercial intercourſe with Africa ſhould ceaſe to be polluted with the blood of its inhabitants. Theſe reſolutions were followed up by a ſuitable report, and ſent to all the country committees throughout the kingdom. At length the ſeſſion ended, and a cruel one it had proved to thoſe who had intereſted themſelves in the abolition of this cruel traffic. The defeat, however, which they had experienced, had been rendered more tolerable, becauſe, in conſequence of the unjuſt clamours by which the minds of many members of parliament had been affected, it had been expected. It had been rendered more tolerable again, by knowing that ſeveral of the moſt diſtinguiſhed characters in the kingdom, and all of ſplendid talents in the houſe of commons, ſuch as Pitt, Fox, Burke, Grey, Sheridan, Wyndham, Whitbread, Courtnay, Francis, Rider, W. Smith, and H. Thornton, had ſupported the ſacred cauſe; and becauſe a bill had been carried through both houſes of parliament in this very ſeſſion for the eſtabliſhment of the Sierra Leona company, the object of which was to form a ſettlement on the coaſt of Africa, which ſhould be made a medium for civilizing that continent through two channels, *viz.* by the introduction of a new ſpecies of commerce there, and of cultivation alſo in its neighbourhood, on the principle of free labour.

The people of England, ſoon after the news of the defeat juſt ſpoken of had been communicated to them, began to be ſenſibly affected, and many, in order to waſh their hands of the blood of Africa, left off the uſe of ſugar. Mr. Clarkſon, after a conſultation with Mr. Wilberforce and the committee, undertook to abridge the evidence which had been offered to the houſe of commons on the ſide of the abolition, with a view of circulating its horrible contents through the kingdom, and of thus making the public impreſſion ſtill deeper. This abridgment was begun in June 1791, and was written, printed, and in the hands of all the committee's correſpondents in England, Wales, and Scotland, by the latter end of September. Mr. Clarkſon now undertook to follow the book, and to ſee, if poſſible, that it was actually read. Accordingly he left London in the beginning of November. It was his intention to wait perſonally upon every perſon in every county in the kingdom, to whom the book had been ſent, to get others of the town or neighbourhood to meet him there, to converſe with them on the ſubject, to intreat their individual peruſal of the abridgment, and their united efforts in lending it out judiciouſly, and in ſeeing that it was read. This he attempted to realize, but the proceſs was very tedious. He had travelled 6000 miles in the execution of his plan, when he found that he had yet 4000 to go. To perform this was impoſſible, ſo as to anſwer the purpoſe. He therefore made his ſituation known to the committee. The conſequence was, that Dr. Dickſon, a gentleman who had greatly aſſiſted the cauſe by his writings, ſet off from London, and took the whole of Scotland off his hands. The reſult of the two journeys was ſoon viſible. The people could not bear the facts which the abridgment had diſcloſed to them. Great numbers left off immediately the uſe both of ſugar and rum. The great bulk of the nation, however, vented their feelings in public meetings to addreſs the legiſlature on the ſubject, and this they did with ſo much earneſtneſs and activity, that by the latter end of the month of March, 1792, no leſs than 517 petitions, including ſeveral from whole counties, were laid on the table of the houſe of commons, praying for the total abolition of the ſlave-trade. Emboldened and ſupported in this manner by the voice of the people, Mr. Wilberforce introduced the queſtion again into the commons. This was on the 2d of April. After a ſpeech of four hours, during which he added a profuſion of new light to the ſubject, and during which he endeavoured, in the moſt mild and perſuaſive manner, to do away objections and prejudices, he moved, "that it is the opinion of this houſe that the African ſlave-trade ought to be aboliſhed." This led to a very long and uncommonly intereſting debate. Never, certainly, in the houſe of commons, and never probably in any other place, was ſo much ſplendid oratory diſplayed, as on that night, on the ſide of the abolition of the ſlave-trade. It appeared, in the courſe of the debate, to be the ſenſe of the houſe, that ſome ſort of abolition ſhould take place. Two diviſions took place. In the firſt, there were 193 votes for gradual abolition, and 125 for immediate; and in the ſecond, there were 230 for gradual, and 85 for no abolition at all. In this ſtate the queſtion was left till the 23d of April, when Mr. Dundas (afterwards lord Melville) came forward and propoſed a plan conformable with the reſolutions of the houſe juſt mentioned. The outlines of it, however, were oppoſed by Meſſrs. Pitt, Fox, and Wilberforce, not only as being very defective, but as built upon falſe data. The buſineſs was accordingly adjourned to the 25th. On that day, Mr. Dundas brought forward the ſubject again. He conſidered that eight years ought to be allowed the planters to ſtock themſelves with negroes, and therefore moved that the year 1800 ſhould be the epoch, after which no more ſlaves ſhould be imported from Africa in Britiſh veſſels to the Weſt Indies. Lord Mornington (now marquis Welleſley), in a moſt brilliant ſpeech, moved an amendment, which was, that the year 1793 ſhould be ſubſtituted for that of 1800. There appeared, on a diviſion, to be 158 for Mr. Dundas's motion, and 109 for the amendment. On the 27th of April the ſubject was reſumed in the houſe. Mr. Dundas propoſed the year 1800, as before, and lord Mornington the year 1795. His lordſhip's motion was again loſt, but by a leſs majority than on the former occaſion, *viz.* by 161 to 121, when ſir Edward Knatchbull ſtruck out a middle line, by propoſing the year 1796, which motion was carried by a majority of 151 to 132. The gradual abolition having been thus agreed upon for 1796, a committee of the commons carried the reſolution to the lords. On the 8th of May the lords met to conſider it, when, cruel to relate, a motion was made by lord Stormont, on the part of the planters, merchants, and other intereſted perſons, to hear new evidence. This, after ſome little oppoſition, was acceded to. On the 15th of May, the firſt witneſs on this ſide of the queſtion was introduced; and on the 5th of June, when only ſeven witneſſes had been examined on the ſame ſide, all further examination was poſtponed to the next ſeſſion.

Nothing could be more diſtreſſing to the abolitioniſts than the determination of the lords now mentioned; firſt, becauſe there was no ſaying how many, even years, the hearing of evidence there might take; and ſecondly, becauſe they (the abolitioniſts) had the laborious work to do over again, of finding out and keeping up a reſpectable body of witneſſes on their own ſide of the queſtion. This latter work was eſſentially neceſſary; for it was impoſſible to allow the perſons intereſted to throw in a weight of teſtimony for the furtherance of their own cauſe, and not to take means to counteract it. Mr. Clarkſon, therefore, ſet out again in the month of July, on his old errand. Dr. Dickſon, the gentleman before-mentioned, left London about the ſame time, in order to aſſiſt him. He was to take a different route, which had been before ſettled. They were very ſucceſsful in their reſpective journeys, and both returned in the month of February, 1793. The houſe of commons was then ſitting. The only ſtep to be taken there (but this was eſſentially neceſſary), was to bring before it, in ſome part or other of the ſeſſion, its own vote of the former year, by which the ſlave-trade was to be aboliſhed in 1796, in order that this vote might be reconſidered and renewed. Accordingly Mr. Wilberforce moved the houſe upon the ſubject. It is only neceſſary to ſtate, that his motion was moſt furiouſly oppoſed, and actually loſt by a majority of 61 to 53. By this determination the commons actually refuſed to ſanction their own vote. In this diſtreſſing ſituation, Mr. Wilberforce ſcarcely knew what to do. He was not, however, to be diſmayed by one unexpected defeat. He reſolved, therefore, that he would not allow the ſeſſion to paſs without trying the queſtion in ſome other ſhape. Accordingly, in the month of May, he moved for leave to bring in a bill to aboliſh that part of the trade by which the Britiſh merchants ſupplied foreigners with ſlaves. His motion was carried, but only by a majority of 7; and, alas! on the third reading, it was loſt by a majority of 31 to 29! During all this time the examination of witneſſes had been going on in the houſe of lords. Only ſeven witneſſes, however, had been heard there in the courſe of the whole ſeſſion.

After this moſt cruel ſeſſion, the abolitioniſts were at a loſs how to act for the advantage of their cauſe. One meaſure, however, was obviouſly neceſſary, *viz.* to endeavour to keep up a reſpectable body of evidence to oppoſe that which ſhould be heard againſt the abolition in the lords. For this purpoſe, Mr. Clarkſon, at the requeſt of the committee, once more traverſed the kingdom. He began his journey in September, and returned in February, 1794. Mr. Wilberforce, in the interim, moved in the commons for leave to renew his former bill for the abolition of the foreign ſlave-trade, as carried on by Britiſh ſubjects. He carried it, though with great difficulty, in all its ſtages, through the houſe of commons; but it was almoſt directly loſt in the houſe of lords. In this latter houſe only two evidences had been examined in the courſe of the ſeſſion. At this time Mr. Clarkſon was in ſuch a wretched ſtate of health, as to be unable to lend any farther aſſiſtance to the committee. The inceſſant labour of body and mind for ſo many years, aggravated by anxiety and diſappointments, had made a very ſerious inroad upon his conſtitution. His nervous ſyſtem had been literally ſhattered to pieces; his hearing, memory, and voice, were nearly gone. He was, in ſhort, utterly incapable of any farther exertion; and he was therefore obliged, though very reluctantly, to be borne out of the field, where he had placed the great honour and glory of his life. The queſtion was now in a very deſperate ſtate, for if the houſe of commons would not renew its own reſolution, and if the lords would not aboliſh even the foreign part of the ſlave-trade, what hope was there of ſucceſs? But neither, however, were Mr. Wilberforce nor the committee to be deterred by the proſpect. They determined never to abandon the cauſe. Accordingly Mr. Wilberforce moved in the commons, in the ſeſſion of 1795, for leave to bring in a bill for the abolition of the ſlave-trade. This motion was now neceſſary, and juſtifiable on that account, if the trade, according to a former reſolution of that houſe, was to ceaſe in 1796; but it was loſt by a ſmall majority.

In the ſeſſion of 1796, Mr. Wilberforce reſolved upon trying the queſtion again, but in an entire new form. He moved that the ſlave-trade be aboliſhed in a limited time, but without aſſigning to its duration any ſpecific date. He wiſhed the houſe to agree to this as a general principle. After much oppoſition the principle was acknowledged; but when, in conſequence of this acknowledgment of it, he brought in a bill, and attempted to introduce into one of the clauſes the year 1797, as the period when the trade ſhould ceaſe, he loſt it by a majority of 74 to 70.

He judged it prudent, after mature conſideration, to let the ſeſſion of 1797 paſs without any parliamentary notice of the ſubject, but in that of 1798 he renewed his motion for abolition in a limited time. This, however, met with the ſame fate as the former.

In 1799, undiſmayed by former defeats, he tried the ſame motion again, when there appeared for it 74, and againſt it 82 votes. He determined, however, that the remainder of the ſeſſion ſhould not paſs without an effort to obtain ſomething, if it were only a ſmall part, of what belonged to the cauſe. Accordingly his eſtimable friend, Mr. Henry Thornton, lately deceaſed, brought in a bill, at his requeſt, to aboliſh a very ſmall part of the ſlave-trade. It may be remembered, that a colony had been eſtabliſhed at Sierra Leona, to promote agriculture and a new ſpecies of commerce in its neighbourhood. Now, while the ſlave-trade was carried on all around it, it was found that theſe objects could be but little advanced. The bill, therefore, of Mr. Thornton, went only ſo far as to ſay that the ſlave-trade ſhould not be carried on within a certain diſtance of that colony. This bill was carried through the commons, but though it only aſked that an infant eſtabliſhment, founded on the principles of liberty, and this by parliamentary ſanction, ſhould be protected from the ravages of the ſlave-trade, it was loſt in the houſe of lords. This latter circumſtance was indeed truly diſheartening; yet amidſt the clouds which darkened the horizon, one gleam of hope appeared; for the queſtion had been ſo argued, ſo ſifted, and put into ſuch various lights, that it began now to be underſtood. The conſequence was, that conviction flaſhed upon many, among whom were three planters, Mr. Ellis, Mr. Barham, and Mr. Vaughan. Theſe gentlemen had the candour to riſe up in the houſe of commons, and expreſs themſelves in favour of the abolition, in one of the laſt debates.

The queſtion had been now tried and loſt in almoſt every poſſible ſhape; Mr. Wilberforce and the committee ſeemed to have but two alternatives of choice left them, either to perſevere againſt all hope, or to hold themſelves in readineſs to ſeize the firſt favourable opportunity which ſhould preſent itſelf for furthering the cauſe. It was determined to adopt the latter, and by no means to let the queſtion degenerate into a mere annual motion of form. It was thought proper alſo, as ſeveral members of the houſe of commons were changing their opinions on the ſubject, to give others time to digeſt the powerful eloquence which had been expended upon it. Mr. Wilberforce, therefore, ſuffered the years 1800, 1801, 1802, and 1803, to paſs over without noticing it. In 1804, however, he reſolved to renew his exertions. The committee reſolved to ſecond them, and immediately increaſed its number, that it might act with extraordinary vigour. The circumſtance, which marked this year in particular as favourable for another trial, was the union with Ireland, in conſequence of which a great number of Iriſh members, generous, and open-hearted, and in general friends to the poor Negroes, were added to the Britiſh parliament. Mr. Wilberforce, therefore, under theſe circumſtances, aſked leave to renew his bill for the abolition of the ſlave-trade within a limited time. This motion was as violently oppoſed as any of the former, but was carried at length in a very handſome manner: no leſs than 124 divided in favour of it, and but 49 againſt it. The bill was oppoſed in its ſecond reading, for which however there were 100, and againſt it but 42. When a motion was made for going into a committee it was oppoſed, but carried by 79 to 20. The bill alſo was oppoſed in its laſt ſtage, but carried by a majority of 69 to 36. It was taken up to the lords, but on a motion by lord Hawkeſbury (now lord Liverpool) the diſcuſſion there was put off till the next ſeſſion.

In the ſeſſion of 1805, Mr. Wilberforce renewed his former motion. Leave was at length given him to bring in the bill, but not till after a moſt furious oppoſition. On the ſecond reading of it the oppoſition increaſed, and an amendment was propoſed, *viz.* to put it off to that day ſix months. This amendment was actually carried by a majority of 77 to 70. This defeat occaſioned the aboliſhioniſts the ſevereſt diſappointment. The committee inſtantly met, when ſorrow was ſeen in the countenances of all preſent. Their firſt object was to endeavour to develope the cauſes of the miſcarriage now mentioned. It appeared clearly, after the moſt minute examination, that theſe were accidental. The committee, therefore, reſolved upon renewing the conteſt with redoubled vigour the enſuing year. Juſt at this moment, who ſhould join them but Mr. Clarkſon! Eight years' retirement had nearly reſtored him, and the firſt moment he found himſelf able to embark again in the cauſe, he returned to his poſt. As it then ſeemed probable that the queſtion would be carried the next year through the commons, and, if ſo, that it would go to the lords, and that the lords would probably require farther evidence, it was judged proper that evidence ſhould be prepared. But, alas! the noble band of witneſſes which had been laſt collected, had been broken by death and diſperſion, and a new one was to be formed. Herculean taſk! tremendous, however, as it was, Mr. Clarkſon undertook it. He left London in two or three days afterward, and returned in January 1806, after having travelled in purſuit of his object above 5000 miles. In this month died Mr. Pitt, who was then prime miniſter, and who had been one of the great ſupporters of the cauſe.

On the 31ſt of March, 1806, this great queſtion was uſhered again into parliament, but under new auſpices, namely, under the adminiſtration of lord Grenville and Mr. Fox. It was thought proper that Mr. Wilberforce ſhould be as it were in the back-ground on this occaſion, and that the attorney-general, as a conſpicuous officer of the government, ſhould introduce it. The latter accordingly brought in a bill, one of the objects of which was to prohibit Britiſh merchants and Britiſh capital from being employed in the foreign ſlave-trade. This bill paſſed both houſes of parliament, and was therefore the firſt that diſmembered this cruel traffic. In the debate which enſued upon it, it was declared in ſubſtance, both by lord Grenville and Mr. Fox, in their reſpective houſes, that they would do every thing to effect the abolition, and ſhould they ſucceed in ſuch a noble work, they would regard their ſucceſs as entailing more true glory on their adminiſtration, and more honour and advantage on the country, than any other meaſure in which they could be engaged. Conformably with this ſentiment, Mr. Fox himſelf, on the 10th of June, in a ſpeech moſt luminous and pathetic, followed up the victory which had been juſt gained, by moving a reſolution, "that this houſe, conſidering the African ſlave-trade to be contrary to the principles of humanity, juſtice, and policy, will, with all practical expedition, take effectual meaſures for the abolition of it, in ſuch manner and at ſuch a period as may be deemed moſt adviſeable." This motion produced an oppoſition as before, and an intereſting debate. It was ſupported by ſir Ralph Milbank, Mr. Francis, ſir Samuel Romilly, Mr. Wilberforce, lord Henry Petty (now marquis of Lanſdown), ſir John Newport, Mr. Canning, and Mr. William Smith. It was carried by a majority of 114 to 15. Mr. Wilberforce directly moved an addreſs to his majeſty, "praying him to direct a negociation to be entered into, by which foreign powers ſhould be invited to co-operate with his majeſty, in meaſures to be adopted for the abolition of the African ſlave-trade." This was alſo carried, but without a diviſion. On the 24th of June, the lords met to conſider both the reſolution and addreſs. A propoſition was directly made in that houſe (in order to create delay), that counſel and evidence ſhould be heard. This, however, was happily overruled. Lord Grenville then roſe up and introduced the ſubject. His ſpeech was among the maſter-pieces of eloquence. He was ſupported in the debate, which followed by the lord chancellor (Erſkine), the biſhop of London (Dr. Porteus), the biſhop of St. Aſaph (Dr. Horſley), earl Groſvenor, earl Stanhope, earl Spencer, earl of Suffolk, and the lords Holland and Ellenborough. The reſolution and addreſs were at length both carried, by a majority of 41 to 20. After this a belief was generally prevalent, that the ſlave-trade would fall in the next ſeſſion. This occaſioned a fear in the abolitioniſts, leſt it ſhould be carried on in the interim, being as it were the laſt harveſt of the merchants, to a tenfold extent, and therefore with tenfold murder and deſolation to Africa. It was therefore thought neceſſary, as the ſeſſion was about to cloſe, to introduce another bill into parliament, and this as quickly as poſſible, that no new veſſel ſhould be permitted to go to the coaſt of Africa for ſlaves. Accordingly a bill to that effect was prepared, and it paſſed both houſes. In the month of October following, after theſe great and deciſive victories, died the right honourable Charles James Fox, one of the nobleſt champions of this noble cauſe. He had lived juſt to put it into a train for final triumph. This triumph, however, he enjoyed in anticipation. The proſpect of it ſoothed his pains, and cheered his ſpirit in the hours of his ſickneſs. At this melancholy ſeaſon it became with him a frequent topic of converſation, and the hope of it was perceived to quiver on his lips, in one of the laſt moments of his life.

The ſeſſion of 1807 had not long commenced, when the conteſt was renewed. Lord Grenville judged it expedient, at this particular criſis, to reverſe what had been hitherto the order of proceeding, that is, to agitate the queſtion firſt in the houſe of lords. On the 2d of January he preſented a bill there, which he called an act for the abolition of the African ſlave-trade. It was very ſhort; he propoſed that it ſhould be printed, and that it ſhould then lie on the table for a while, that it might be maturely conſidered before it was diſcuſſed. On the 4th, no leſs than four counſel were heard againſt it. On the 5th the debate commenced. Lord Grenville took a brilliant part in it. He was ſupported by his highneſs the duke of Glouceſter, the biſhop of Durham (Dr. Barrington), the earls Moira, Selkirk, and Roſslyn, and the lords Holland, King, and Hood. The bill was at length carried, at four in the morning, by a majority of 100 to 36. On the 10th of February it went to the commons. On the 20th counſel were heard againſt it there. On the 23d a debate enſued upon it, on the motion of lord viſcount Howick (formerly Mr. Grey, and now lord Grey), who urged the commons to confirm it. The other ſpeakers in favour of it were Mr. Roſcoe, Mr. Fawkes, Mr. Luſhington, the lords Mahon and Milton, ſir Samuel Romilly, ſir John Doyle, Mr. Wilberforce, and earl Percy; and it was carried by the vaſt majority of 283 to 16. On the 6th of March the blanks were filled up. It was propoſed, firſt, that no veſſel ſhould clear out for ſlaves from any port within the Britiſh dominions, after the 1ſt of May following, that is, 1807, and that no ſlave ſhould be landed in the Britiſh colonies after the 1ſt of March 1808. This and almoſt every other propoſition were oppoſed, but happily without effect. Suffice it to ſay, that on the 18th the bill, with the blanks filled up, was carried back to the lords; that in conſequence of various amendments, it paſſed and repaſſed from one houſe to the other, but always with oppoſition; that on the 24th it paſſed both houſes; and that on the 25th, at half paſt eleven in the morning, it received the royal aſſent. Thus paſſed, after a twenty years' hard ſtruggle, during which the field had been diſputed inch by inch, and won at laſt by the arms of reaſon, this magna charta for Africa in Britain, under the adminiſtration of lord Grenville and Mr. Fox, an adminiſtration which, on account of its noble exertions in behalf of the oppreſſed African race, will paſs to poſterity, living through ſucceſſive generations, in the love and gratitude of all the moſt virtuous of mankind. The news of this great event gave uncommon joy throughout the kingdom, and this joy was farther heightened by authentic news juſt then received from North America, that the government there had paſſed a ſimilar bill, which was to be obſerved as a law through the United States.

In France, on the re-eſtabliſhment of the Bourbon dynaſty, it was propoſed to aboliſh the ſlave-trade at a diſtant period. Upon the return of Bonaparte from Elba, an order was iſſued for its immediate abolition; and a decree to the ſame purpoſe has been paſſed ſince the expulſion of Napoleon, and the reſtoration of the preſent reigning monarch.

SLAVE-COAST, in *Geography*, a tract of country in Africa, bordering on the Atlantic, ſituated between the Gold Coaſt and Benin, and comprehending the kingdoms of Ardra, Koto, Popo, and Whidah. See each reſpectively, and alſo SLAVE-TRADE.

The inhabitants reſemble thoſe of the Gold Coaſt in their politics, religion, and manners.

SLAVE-FALLS, a cataract of North America, in Winnipeg river, 100 yards wide and 20 feet in height. N. lat. 50° 6′. W. long. 95° 20′.

SLAVE-INDIANS, Indians of North America, who were driven from their original country by their enemies the Kniſteneaux, along the borders of the Unjigah or Peace river, where it aſſumes from them the name of the Slave river; though the term by no means involves the idea of ſervitude, but was given to thoſe fugitives as a term of reproach, that denoted more than common ſavageneſs.

SLAVE-LAKE, *Great*, a large lake of North America, ſo called by the Kniſteneaux, which derived its name from that of its original inhabitants, who were called ſlaves. This lake is well known to the Kniſteneaux, who are among the inhabitants of the plains on the banks of the Saſkatchiwine river; for formerly, when they uſed to make war in this country, they came in their canoes to that lake, and left them there; from whence there is a beaten path all the way to the Forks, or E. branch of this river, which was their war-road. This lake is ſaid to be more than 200 miles in length, and about 12 in breadth. It is ſuppoſed to be the ſame with Hearne's *Athapuſcow*, which ſee. Bitumen is found on the coaſt of this lake, in N. lat. 60°, near its diſcharge by Mackenzie's river, which, flowing from Slave-lake, diſcharges itſelf into the North ſea, on the banks of which are coal and bitumen, as far north as latitude 66°. N. lat. 61° 20′. W. long. 115°.

SLAVE-LAKE, *Leſſer*, a lake of North America, in N. lat. 55° 30′. W. long. 115°, which diſcharges itſelf into the Elk river.

SLAVENSK, a town of Ruſſia, in the government of Ekaterinoſlav, on the Dnieper; 48 miles S. of Ekaterinoſlav. N. lat. 47° 24′. E. long. 34° 44′.

SLAVE-RIVER, a river of North America, being a continuation of Unjigah or Peace river, which diſcharges itſelf into the greater Slave-lake. Near that part of the Slave-river, where it firſt loſes the name of Peace river, and along the extreme edge of the adjoining plains, are very ſtrong ſalt ſprings, which in the ſummer concrete and cryſtallize in great quantities.

SLAUGHTER. See MANSLAUGHTER, HOMICIDE, MURTHER, BUTCHER, &c.

SLAUGHTER-*Houſe*, in *Rural Practice*, the place where neat cattle and other animals are killed for the butcher. In common houſes for this purpoſe, the blood, filth, and other naſtineſs are left to remain upon the floors; but in thoſe of the improved kind, the floors are laid in ſuch a manner as to have a proper full degree of fall or declination towards the thing, if it were only a ſmall part, of what belonged to the cauſe. Accordingly his eſtimable friend, Mr. Henry Thornton, lately deceaſed, brought in a bill, at his requeſt, to aboliſh a very ſmall part of the ſlave-trade. It may be remembered, that a colony had been eſtabliſhed at Sierra Leona, to promote agriculture and a new ſpecies of commerce in its neighbourhood. Now, while the ſlave-trade was carried on all around it, it was found that theſe objects could be but little advanced. The bill, therefore, of Mr. Thornton, went only ſo far as to ſay that the ſlave-trade ſhould not be carried on within a certain diſtance of that colony. This bill was carried through the commons, but though it only aſked that an infant eſtabliſhment, founded on the principles of liberty, and this by parliamentary ſanction, ſhould be protected from the ravages of the ſlave-trade, it was loſt in the houſe of lords. This latter circumſtance was indeed truly diſheartening; yet amidſt the clouds which darkened the horizon, one gleam of hope appeared; for the queſtion had been ſo argued, ſo ſifted, and put into ſuch various lights, that it began now to be underſtood. The conſequence was, that conviction flaſhed upon many, among whom were three planters, Mr. Ellis, Mr. Barham, and Mr. Vaughan. Theſe gentlemen had the candour to riſe up in the houſe of commons, and expreſs themſelves in favour of the abolition, in one of the laſt debates.

The queſtion had been now tried and loſt in almoſt every poſſible ſhape; Mr. Wilberforce and the committee ſeemed to have but two alternatives of choice left them, either to perſevere againſt all hope, or to hold themſelves in readineſs to ſeize the firſt favourable opportunity which ſhould preſent itſelf for furthering the cauſe. It was determined to adopt the latter, and by no means to let the queſtion degenerate into a mere annual motion of form. It was thought proper alſo, as ſeveral members of the houſe of commons were changing their opinions on the ſubject, to give others time to digeſt the powerful eloquence which had been expended upon it. Mr. Wilberforce, therefore, ſuffered the years 1800, 1801, 1802, and 1803, to paſs over without noticing it. In 1804, however, he reſolved to renew his exertions. The committee reſolved to ſecond them, and immediately increaſed its number, that it might act with extraordinary vigour. The circumſtance, which marked this year in particular as favourable for another trial, was the union with Ireland, in conſequence of which a great number of Iriſh members, generous, and open-hearted, and in general friends to the poor Negroes, were added to the Britiſh parliament. Mr. Wilberforce, therefore, under theſe circumſtances, aſked leave to renew his bill for the abolition of the ſlave-trade within a limited time. This motion was as violently oppoſed as any of the former, but was carried at length in a very handſome manner: no leſs than 124 divided in favour of it, and but 49 againſt it. The bill was oppoſed in its ſecond reading, for which however there were 100, and againſt it but 42. When a motion was made for going into a committee it was oppoſed, but carried by 79 to 20. The bill alſo was oppoſed in its laſt ſtage, but carried by a majority of 69 to 36. It was taken up to the lords, but on a motion by lord Hawkeſbury (now lord Liverpool) the diſcuſſion there was put off till the next ſeſſion.

In the ſeſſion of 1805, Mr. Wilberforce renewed his former motion. Leave was at length given him to bring in the bill, but not till after a moſt furious oppoſition. On the ſecond reading of it the oppoſition increaſed, and an amendment was propoſed, *viz.* to put it off to that day ſix months. This amendment was actually carried by a majority of 77 to 70. This defeat occaſioned the aboliitioniſts the ſevereſt diſappointment. The committee inſtantly met, when ſorrow was ſeen in the countenances of all preſent. Their firſt object was to endeavour to develope the cauſes of the miſcarriage now mentioned. It appeared clearly, after the moſt minute examination, that theſe were accidental. The committee, therefore, reſolved upon renewing the conteſt with redoubled vigour the enſuing year. Juſt at this moment, who ſhould join them but Mr. Clarkſon! Eight years' retirement had nearly reſtored him, and the firſt moment he found himſelf able to embark again in the cauſe, he returned to his poſt. As it then ſeemed probable that the queſtion would be carried the next year through the commons, and, if ſo, that it would go to the lords, and that the lords would probably require farther evidence, it was judged proper that evidence ſhould be prepared. But, alas! the noble band of witneſſes which had been laſt collected, had been broken by death and diſperſion, and a new one was to be formed. Herculean taſk! tremendous, however, as it was, Mr. Clarkſon undertook it. He left London in two or three days afterward, and returned in January 1806, after having travelled in purſuit of his object above 5000 miles. In this month died Mr. Pitt, who was then prime miniſter, and who had been one of the great ſupporters of the cauſe.

On the 31ſt of March, 1806, this great queſtion was uſhered again into parliament, but under new auſpices, namely, under the adminiſtration of lord Grenville and Mr. Fox. It was thought proper that Mr. Wilberforce ſhould be as it were in the back-ground on this occaſion, and that the attorney-general, as a conſpicuous officer of the government, ſhould introduce it. The latter accordingly brought in a bill, one of the objects of which was to prohibit Britiſh merchants and Britiſh capital from being employed in the foreign ſlave-trade. This bill paſſed both houſes of parliament, and was therefore the firſt that diſmembered this cruel traffic. In the debate which enſued upon it, it was declared in ſubſtance, both by lord Grenville and Mr. Fox, in their reſpective houſes, that they would do every thing to effect the abolition, and ſhould they ſucceed in ſuch a noble work, they would regard their ſucceſs as entailing more true glory on their adminiſtration, and more honour and advantage on the country, than any other meaſure in which they could be engaged. Conformably with this ſentiment, Mr. Fox himſelf, on the 10th of June, in a ſpeech moſt luminous and pathetic, followed up the victory which had been juſt gained, by moving a reſolution, "that this houſe, conſidering the African ſlave-trade to be contrary to the principles of humanity, juſtice, and policy, will, with all practical expedition, take effectual meaſures for the abolition of it, in ſuch manner and at ſuch a period as may be deemed moſt adviſeable." This motion produced an oppoſition as before, and an intereſting debate. It was ſupported by ſir Ralph Milbank, Mr. Francis, ſir Samuel Romilly, Mr. Wilberforce, lord Henry Petty (now marquis of Lanſdown), ſir John Newport, Mr. Canning, and Mr. William Smith. It was carried by a majority of 114 to 15. Mr. Wilberforce directly moved an addreſs to his majeſty, "praying him to direct a negociation to be entered into, by which foreign powers ſhould be invited to co-operate with his majeſty, in meaſures to be adopted for the abolition of the African ſlave-trade." This was alſo carried, but without a diviſion. On the 24th of June, the lords met to conſider both the reſolution and addreſs. A propoſition was directly made in that houſe (in order to create delay), that counſel and evidence ſhould be heard. This, however, was happily over-ruled. Lord Grenville then roſe up and introduced the ſubject. His ſpeech was among the maſter-pieces of eloquence. He was ſupported in the debate, which followed by the lord chancellor (Erſkine), the biſhop of London (Dr. Porteus), the biſhop of St. Aſaph (Dr. Horſley), earl Groſvenor, earl Stanhope, earl Spencer, earl of Suffolk, and the lords Holland and Ellenborough. The reſolution and addreſs were at length both carried, by a majority of 41 to 20. After this a belief was generally prevalent, that the ſlave-trade would fall in the next ſeſſion. This occaſioned a fear in the abolitioniſts, leſt it ſhould be carried on in the interim, being as it were the laſt harveſt of the merchants, to a tenfold extent, and therefore with tenfold murder and deſolation to Africa. It was therefore thought neceſſary, as the ſeſſion was about to cloſe, to introduce another bill into parliament, and this as quickly as poſſible, that no new veſſel ſhould be permitted to go to the coaſt of Africa for ſlaves. Accordingly a bill to that effect was prepared, and it paſſed both houſes. In the month of October following, after theſe great and deciſive victories, died the right honourable Charles James Fox, one of the nobleſt champions of this noble cauſe. He had lived juſt to put it into a train for final triumph. This triumph, however, he enjoyed in anticipation. The proſpect of it ſoothed his pains, and cheered his ſpirit in the hours of his ſickneſs. At this melancholy ſeaſon it became with him a frequent topic of converſation, and the hope of it was perceived to quiver on his lips, in one of the laſt moments of his life.

The ſeſſion of 1807 had not long commenced, when the conteſt was renewed. Lord Grenville judged it expedient, at this particular criſis, to reverſe what had been hitherto the order of proceeding, that is, to agitate the queſtion firſt in the houſe of lords. On the 2d of January he preſented a bill there, which he called an act for the abolition of the African ſlave-trade. It was very ſhort; he propoſed that it ſhould be printed, and that it ſhould then lie on the table for a while, that it might be maturely conſidered before it was diſcuſſed. On the 4th, no leſs than four counſel were heard againſt it. On the 5th the debate commenced. Lord Grenville took a brilliant part in it. He was ſupported by his highneſs the duke of Glouceſter, the biſhop of Durham (Dr. Barrington), the earls Moira, Selkirk, and Roſslyn, and the lords Holland, King, and Hood. The bill was at length carried, at four in the morning, by a majority of 100 to 36. On the 10th of February it went to the commons. On the 20th counſel were heard againſt it there. On the 23d a debate enſued upon it, on the motion of lord viſcount Howick (formerly Mr. Grey, and now lord Grey), who urged the commons to confirm it. The other ſpeakers in favour of it were Mr. Roſcoe, Mr. Fawkes, Mr. Luſhington, the lords Mahon and Milton, ſir Samuel Romilly, ſir John Doyle, Mr. Wilberforce, and earl Percy; and it was carried by the vaſt majority of 283 to 16. On the 6th of March the blanks were filled up. It was propoſed, firſt, that no veſſel ſhould clear out for ſlaves from any port within the Britiſh dominions, after the 1ſt of May following, that is, 1807, and that no ſlave ſhould be landed in the Britiſh colonies after the 1ſt of March 1808. This and almoſt every other propoſition were oppoſed, but happily without effect. Suffice it to ſay, that on the 18th the bill, with the blanks filled up, was carried back to the lords; that in conſequence of various amendments, it paſſed and repaſſed from one houſe to the other, but always with oppoſition; that on the 24th it paſſed both houſes; and that on the 25th, at half paſt eleven in the morning, it received the royal aſſent. Thus paſſed, after a twenty years' hard ſtruggle, during which the field had been diſputed inch by inch, and won at laſt by the arms of reaſon, this magna charta for Africa in Britain, under the adminiſtration of lord Grenville and Mr. Fox, an adminiſtration which, on account of its noble exertions in behalf of the oppreſſed African race, will paſs to poſterity, living through ſucceſſive generations, in the love and gratitude of all the moſt virtuous of mankind. The news of this great event gave uncommon joy throughout the kingdom, and this joy was farther heightened by authentic news juſt then received from North America, that the government there had paſſed a ſimilar bill, which was to be obſerved as a law through the United States.

In France, on the re-eſtabliſhment of the Bourbon dynaſty, it was propoſed to aboliſh the ſlave-trade at a diſtant period. Upon the return of Bonaparte from Elba, an order was iſſued for its immediate abolition; and a decree to the ſame purpoſe has been paſſed ſince the expulſion of Napoleon, and the reſtoration of the preſent reigning monarch.

SLAVE-COAST, in *Geography*, a tract of country in Africa, bordering on the Atlantic, ſituated between the Gold Coaſt and Benin, and comprehending the kingdoms of Ardra, Koto, Popo, and Whidah. See each reſpectively, and alſo SLAVE-TRADE.

The inhabitants reſemble thoſe of the Gold Coaſt in their politics, religion, and manners.

SLAVE-FALLS, a cataract of North America, in Winnipeg river, 100 yards wide and 20 feet in height. N. lat. 50° 6'. W. long. 95° 20'.

SLAVE-INDIANS, Indians of North America, who were driven from their original country by their enemies the Kniſteneaux, along the borders of the Unjigah or Peace river, where it aſſumes from them the name of the Slave river; though the term by no means involves the idea of ſervitude, but was given to thoſe fugitives as a term of reproach, that denoted more than common ſavageneſs.

SLAVE-LAKE, *Great*, a large lake of North America, ſo called by the Kniſteneaux, which derived its name from that of its original inhabitants, who were called ſlaves. This lake is well known to the Kniſteneaux, who are among the inhabitants of the plains on the banks of the Saſkatchiwine river; for formerly, when they uſed to make war in this country, they came in their canoes to that lake, and left them there; from whence there is a beaten path all the way to the Forks, or E. branch of this river, which was their war-road. This lake is ſaid to be more than 200 miles in length, and about 12 in breadth. It is ſuppoſed to be the ſame with Hearne's *Athapuſcow*, which ſee. Bitumen is found on the coaſt of this lake, in N. lat. 60°, near its diſcharge by Mackenzie's river, which, flowing from Slave-lake, diſcharges itſelf into the North ſea, on the banks of which are coal and bitumen, as far north as latitude 66°. N. lat. 61° 20'. W. long. 115°.

SLAVE-LAKE, *Leſſer*, a lake of North America, in N. lat. 55° 30'. W. long. 115°, which diſcharges itſelf into the Elk river.

SLAVENSK, a town of Ruſſia, in the government of Ekaterinoſlav, on the Dnieper; 48 miles S. of Ekaterinoſlav. N. lat. 47° 24'. E. long. 34° 44'.

SLAVE-RIVER, a river of North America, being a continuation of Unjigah or Peace river, which diſcharges itſelf into the greater Slave-lake. Near that part of the Slave-river, where it firſt loſes the name of Peace river, and along the extreme edge of the adjoining plains, are very ſtrong ſalt ſprings, which in the ſummer concrete and cryſtallize in great quantities.

SLAUGHTER. See MANSLAUGHTER, HOMICIDE, MURTHER, BUTCHER, &c.

SLAUGHTER-*Houſe*, in *Rural Practice*, the place where neat cattle and other animals are killed for the butcher. In common houſes for this purpoſe, the blood, filth, and other naſtineſs are left to remain upon the floors; but in thoſe of the improved kind, the floors are laid in ſuch a manner as to have a proper full degree of fall or declination towards the middle parts, where there is a drain made for taking away all ſuch offenſive matters, and keeping the houſes quite clean and ſweet, merely by pumping or throwing water upon the floors of them.

Houſes of this ſort have uſually the dimenſions of about twenty-two feet in length by ſixteen in width; but they may be conſtructed in this way to any ſuitable extent that may be neceſſary. The drains of ſlaughter-houſes are often connected with pits or reſervoirs, by which means large quantities of excellent manure are accumulated.

Theſe houſes, likewiſe, ſometimes form parts in the arrangement of farm buildings in large farm-yards.

SLAUGHTER-*Skins*, a term uſed by our curriers and leather-dreſſers for the ſkins of oxen, or other beaſts, when freſh, and covered with the hair: ſuch as they receive them from the ſlaughter-houſes where the butchers flay the carcaſe.

SLAUGHTER *Creek*, in *Geography*, a bay of America, on the coaſt of Maryland, in the Cheſapeak.

SLAUGHTERING *of Animals*, the cuſtom of killing them for the purpoſe of food. This operation, for the ſake of humanity, ſhould conſtantly be performed in the moſt ſudden and ready manner poſſible, and not in the lingering, brutal, protracted way which is uſually practiſed by the generality of butchers in this country. See STRIKING *or Pithing Animals*.

SLAVI, SLAVONIA, and SLAVONIANS. See SCLAVI, SCLAVONIA, and SCLAVONIANS.

SLAWATICZE, in *Geography*, a town of Lithuania, in the palatinate of Brzeſc, near the Bug; 16 miles S. of Brzeſc.

SLAWENTITZ, a town of Sileſia, in the principality of Oppeln; 24 miles S.E. of Oppeln.

SLAWIETIN, a town of Bohemia, in the circle of Schlan; 12 miles N.W. of Schlan.

SLAWKOW, a town of Auſtrian Poland, in the palatinate of Cracow; 25 miles N.W. of Cracow.

SLAWKOW. See AUSTERLITZ and SCHLAKENWALD.

SLAWONICA. See ZLABINGS.

SLEAFORD, or NEW SLEAFORD, a market-town in the wapentake of Flaxwell, parts of Keſteven, and county of Lincoln, England, is ſituated 16 miles S. of Lincoln and 116 N. of London, on a ſmall rivulet called the Slea, which riſes in the vicinity, and runs to Chapel Hill, where it joins the river Witham. Many Roman coins of the Conſtantine family have been found here, from which, and other circumſtances, Dr. Stukeley conjectures, that this was a Roman town. "We find the diſtance," he obſerves, "between Caſtor and Lincoln about forty miles, has two towns upon it at proper intervals for lodging: theſe are Sleaford and Stanfield. The original names of them are in irrecoverable ſilence, but the eternity of the Romans is inherent. It is probable that Alexander, biſhop of Lincoln, built his work upon the ſcite of a Roman citadel. Beſide, at Sleaford comes in the other Roman road from the fen country by Brig End Cauſy, and at the interſection of theſe two roads the old town ſtood." The work here alluded to was the caſtle, which, in Leland's time, was ſtanding, and is thus deſcribed by him. "Withoute the towne of Sleford ſtandith, weſt-ſouth-weſt, the propre caſtell of Sleford, very well mantayned; and it is compaſſed with a renning ſtreme, cumming by a cut oute of a little feene, lying almoſte flatte weſte againſt it. In the gateway be two portcuſliſes, a high towre in the middle of the caſtelle, but not ſet upon a hill of raiſed earth: the vaults of the caſtle by the ground be fair. The houſe, or manor place, lately almoſt new, buildid of ſtone and timbre, ſtandith ſouthward without the town. The town nor market is of no price: the ornaments of it is the biſhop of Lincoln's caſtle, and the late lord Huſſey's houſe." Since Leland's time, however, Sleaford has become a different place, and is ſtill improving both as to buildings and population. In the return to parliament in the year 1811, the houſes are ſtated to be 385, the inhabitants 1781. The caſtle has been wholly levelled with the ground, and lord Huſſey's manſion, at Old Sleaford, is now a farm-houſe. A weekly market is held on Mondays, and four fairs are held annually.

The church is a handſome, ſpacious ſtructure, and, from a manuſcript found in the pariſh cheſt, appears to have been built in the year 1271, by Roger Blunt and Roger Brickham, of Sleaford, merchants. It conſiſts of a chancel, nave, tranſept, and two aiſles; with a tower crowned by a ſpire, which riſes to the height of 144 feet. In the chancel are ſeveral monuments to the family of Carr, by one of which a free-ſchool was erected and liberally endowed in the year 1603; and alſo an hoſpital for twelve poor men. The manor and eſtates were conveyed by marriage, with an heireſs of the Carr family, to the late earl of Briſtol.

At Kyme, about three miles from Sleaford, Leland ſays, there was in his time "a goodly houſe and park." Philip de Kyme, in the reign of Henry II., built here a priory for black canons of the order of St. Auguſtine, to the honour of the Bleſſed Virgin. Its ſurrender by a prior and nine canons to Henry VIII. is noticed by Willis.

About ſeven miles eaſt of Sleaford, is Haverholme priory, the ſeat of ſir Jeniſon William Gordon, bart. The houſe and grounds occupy an area of about 300 acres, which conſtitute an iſland, formed by two branches of a river. It was given by biſhop Alexander, in 1139, to the nuns and canons of the order of St. Gilbert of Sempringham; and at the diſſolution was granted to Edward, lord Clinton. The preſent poſſeſſor of Haverholme made numerous additions to the old remains in 1788, and has formed a manſion in a ſtyle correſponding with the importance of the place. Beauties of England and Wales, vol. ix. by J. Britton, F.S.A.

SLEAMORE POINT, the ſouthern extremity of the iſland of Iniſherkan, oppoſite to Baltimore, in the county of Cork, Ireland. N. lat. 51° 24′. W. long. 9° 19′.

SLEASY HOLLAND, a kind of holland thus called, becauſe made in Sileſia in Germany; and which, from its ſlightneſs, occaſions all thin, ſlight, ill-wrought hollands, to be called *ſleaſy*.

SLEBEZE, or SLYBZE, in *Geography*, a ſmall iſland in the ſtraits of Sunda. S. lat. 5° 54′. E. long. 105° 24′.

SLECK, in *Rural Economy*, a provincial term applied to the ſmall of pit-coal: alſo to the black matter of ſmutty grain.

SLED, in *Agriculture*, provincially a ſledge.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge ſtones, bells, &c. The ſledge for carrying criminals, condemned for high treaſon, to execution, is called *hurdle*.

The Dutch have a kind of ſledge, on which they can carry a veſſel of any burden by land. It conſiſts of a plank of the length of the keel of a moderate ſhip, raiſed a little behind, and hollow in the middle; ſo that the ſides go a little aſlope, and are furniſhed with holes to receive pins, &c. The reſt is quite even.

SLEDGE, in *Agriculture*, an implement employed for conveying various articles upon. It is made of two ſtrong pieces of wood framed together.

It is a very uſeful ſort of contrivance for different kinds of work and purpoſes in farming in different ſituations of land, but eſpecially thoſe that are rather of a hilly nature; ſuch as the conveying away various ſorts of heavy materials, as thoſe of ſtones and earthy matters, and in ſome inſtances the produce of the land. Sledges alſo ſerve the purpoſe of tranſporting ploughs and other heavy tools of agriculture to the different fields and other places where they are to be uſed or employed, being contrived expreſsly for ſuch uſes and intentions. They are a kind of tool, which are made much uſe of in many of the northern diſtricts of the kingdom, as well as in ſome of the ſouthern ones.

In the county of Cornwall they employ a ſort of ſledge or dray, on moſt farms, for the carriage of their hay, corn, faggot-wood, and many other matters. Their ſledges moſtly conſiſt of two ſtrong ſide-pieces of wood, ſomewhat in the form of a common boat, only more ſharply turned upwards at the ends, which have five, ſix, and ſometimes ſeven croſs-bars mortiſed into each, being ſhod below with thick rough portions of ſtrong timber, on which the whole ſlides upon the ſurface of the ground.

In ſome caſes two, ſmall, low wheels are attached, on which the machine moves. Theſe ſledges are drawn either by horſes or oxen in the above diſtrict, and are found to be handy and convenient in various ways.

SLEDGE is a large ſmith's hammer, to be uſed with both hands: of this there are two ſorts, the *up-hand ſledge*, which is uſed by under workmen, when the work is not of the largeſt ſort; it is uſed with both the hands before, and they ſeldom raiſe it higher than their head. But the other, which is called the *about-ſledge*, and which is uſed for battering or drawing out the largeſt work, is held by the handle with both hands, and ſwung round over their heads, at their arms end, to ſtrike as hard a blow as they can.

SLEDGE, among *Miners*. See DIGGING.

SLEDGES, in *Rope-making*, are frames of oak mortiſed together, and clamped with iron in different parts. They are from three feet wide, and eight or twelve feet long, to five feet wide and fifteen feet long. The two ſides are the length of the ſledge, five by ſeven inches thick, and tied in by oak bars at each end: near the front are two uprights five feet high, mortiſed into the ſides, and ſupported by two ſlanting pieces from the upper end. A breaſt-board nine inches wide, and from three to five inches thick, is faſtened with iron pins to the uprights, and contains holes for the hooks to go through, on which the yarn is hung, which being turned by men, is twiſted into ſtrands, and then cloſed and finiſhed into rope. Theſe ſledges are loaded to any degree the rope in making may require.

SLEDGE *Iſland*, in *Geography*, an iſland in the North Pacific ocean, near the weſt coaſt of North America; about 12 miles in circuit. This iſland is compoſed of large looſe ſtones, covered with moſs and other vegetables, of which there are twenty or thirty different ſpecies, moſtly in flower. Captain Cook ſaw neither ſhrub nor tree, either upon the iſland or continent. He obſerved one fox, a few plover, and other ſmall birds, and alſo ſome decayed huts conſtructed partly below the ground. A beaten path was ſeen from one end of the iſland to the other, and theſe circumſtances indicated its having been lately viſited by ſome people. A ſledge alſo was found, which gave name to the iſland: this was ſuch as the Ruſſians in Kamtſchatka uſed to convey goods from one place to another, over the ice or ſnow. It was 10 feet long, 20 inches broad; it had a kind of railwork on each ſide, and was ſhod with bone. Its conſtruction was admirable, its parts being neatly put together, partly with wooden pins, but principally with thongs or laſhings of whale-bone. N. lat. 64° 50′. W. long. 166° 3′.

SLEDINGEN, a town of France, in the department of the Scheld; 5 miles N. of Ghent.

SLEEAN, in *Rural Economy*, provincially the ſmut in corn.

SLEEP, in *Phyſiology*, the more or leſs complete ſuſpenſion of the functions of ſenſation and volition, that is, of the action of the five ſenſes, of the brain, of the voluntary muſcles, and the voice, or the organs which connect us with the external world, to which animals, at leaſt thoſe of the claſſes mammalia and birds, are ſubject at certain more or leſs regular intervals, for the purpoſe of renewing the power of action exhauſted by exerciſe.

In the article LIFE we have ſtated, that the internal functions, which make up the *organic* life, differ remarkably from the external, which compoſe the *animal* life, in the duration of their action; that while the former go on inceſſantly, the latter are ſubject to intermiſſions or periods of complete repoſe, each particular organ experiencing, from its activity, an exhauſtion of power, a fatigue, which renders reſt abſolutely neceſſary before it can be again exerted; which exhauſtion or fatigue is unknown in the organic life. This law, of the intermiſſion of action, has been very ſatisfactorily applied by Bichat to the theory of ſleep. "General ſleep," ſays he, "is the aſſemblage of particular ſleeps. It is derived from that law of the animal life, which cauſes in its functions a conſtant ſucceſſion of periods of activity, and times of intermiſſion;—a law, which pointedly diſtinguiſhes it from the organic life. Hence ſleep influences the latter only in an indirect way, while it exerts its full operation on the former.

"Numerous varieties may be remarked in this periodic ſtate, to which all animals are expoſed. The moſt complete ſleep is that, in which the whole external life, that is, the ſenſes, perception, imagination, memory, judgment, locomotion, and the voice, are ſuſpended; the leaſt perfect affects only a ſingle organ. We ſee numerous gradations between theſe two extremes; ſometimes the ſenſes, perception, locomotion, and the voice, are ſuſpended; imagination, memory, and judgment remaining active; ſometimes locomotion and the voice are added to the latter. Such is the ſleep which is agitated by dreams. A portion of the animal life ſtill continues active, having eſcaped the torpidity in which the reſt is plunged. Three or four ſenſes only may have paſſed into the ſtate of repoſe, and ceaſed to be influenced by external objects; then that kind of ſomnambuliſm occurs, in which, to the action of the brain, the muſcles, and the larynx, are added thoſe of hearing and touch, often in a very diſtinct form.

"Let us then no longer regard ſleep as a conſtant ſtate, invariable in its phenomena. Scarcely do we ſleep twice together in the ſame way; a multitude of cauſes modifies this condition of our being, by applying to a greater or ſmaller portion of the animal life the general law of intermittent action. The various modifications muſt be characteriſed by the functions, which are affected in different inſtances. The principle is the ſame throughout, from the ſimple relaxation, which follows the contraction of a voluntary muſcle, to the entire ſuſpenſion of the animal life. Sleep is in all caſes a conſequence of that general law of intermiſſion, which excluſively characteriſes this life, but the application of which to the various external functions varies infinitely.

"This explanation of ſleep is undoubtedly very different from thoſe narrow ſyſtems, which place its cauſe in the brain, the heart, the large veſſels, the ſtomach, &c. and thus preſent an inſulated phenomenon, often illuſory, as the baſis of one of the great modifications of life.

"Why do light and darkneſs, in the natural order of things, correſpond reſpectively to the activity and repoſe of the external functions? Becauſe, during the day, the animal is ſurrounded with a multitude of exciting cauſes; a thouſand things exhauſt the powers of the ſentient and locomotive organs, fatigue them, and thus prepare a relaxation, which is favoured at night by the abſence of all ſtimuli. Thus, in the modern way of life, in which this order is partly inverted, we aſſemble round us, during the night, various ſtimuli, which prolong the ſtate of watchfulneſs, and make the intermiſſion of the animal life coincide with the firſt hours of the dawn, favouring it by removing all circumſtances that might produce ſenſations.

"By multiplying around them cauſes of excitation, we can, for a certain time, prevent the organs of the animal life from obeying the law of intermiſſion; but they yield at laſt, and nothing, after a certain time, can ſuſpend its influence. Exhauſted by continued exertion, the ſoldier ſleeps at the ſide of the cannon, and the criminal even amid the tortures of the queſtion.

"Let us, however, diſtinguiſh natural ſleep, the conſequence of fatigue of the organs, from that which is cauſed by affections of the brain, as apoplexy, or concuſſion. In the latter caſe the ſenſes are awake, they receive impreſſions, and are affected by them as uſual; but theſe impreſſions cannot be perceived by the diſordered brain, and we conſequently are not conſcious of them. In ſleep, on the contrary, the intermiſſion of action affects the ſenſes as much, and even more than the brain." Recherches Phyſiol. ſur la Vie et la Mort, p. 34—37.

Although the remarks of Bichat in the preceding quotation, reſpecting the ſleep of the particular ſenſes, may be regarded rather as illuſtrations, than as proofs that the ſtate of fatigue from exertion of any particular organ is exactly the ſame as its condition in ſleep, we conſider the general view of the ſubject as perfectly correct. In the moſt complete ſleep, our relations to external objects are entirely ſuſpended, and conſciouſneſs undergoes an equally complete interruption. The appropriate ſtimuli, preſented to the external ſenſes, excite no ſenſations; the operations of the mind do not go on; hence there is nothing to excite volition, and the voluntary powers are conſequently quieſcent. The portion of exiſtence paſſed in ſuch ſleep is a perfect blank. We have examples of it in the moſt tranquil and healthy ſtates of the body and mind, and after conſiderable fatigue, or in the recovery from ſevere and painful diſeaſe.

But this ſound ſleep is much leſs common, than that which is more or leſs interrupted by dreams, in which a ſeries of ſenſations, perceptions, and reflections, paſſes through the mind, as in the waking ſtate. We are conſcious of the ſame kind of tranſactions as occupy our waking hours; we ſee, hear, walk, talk, and perform all the cuſtomary offices of life. The mind reaſons, judges, performs volition, and experiences the various affections, as love, hatred, indignation, anxiety, fear, joy, even in a much more lively degree, than when they are excited by their real cauſes. In dreaming, as in the ſoundeſt ſleep, the action of the external ſenſes is ſuſpended; but the internal faculties are active in greater or leſs number. Volition takes place, but the muſcles do not obey the will. That dreaming is a leſs ſound ſpecies of ſleep, appears from the familiar fact, which has probably been obſerved by every individual; *viz.* that the firſt ſleep is much freer from it than the ſecond. We retire to reſt, fatigued by the exertions of the day, and ſleep ſoundly for five or ſix hours: we wake, and then fall aſleep again towards the morning, and dream the whole time of this ſecond ſleep.

Haller, who mentions that he had attended much to his dreams, obſerves, that in perfect health he remembered only the ſenſation of flying through the air, conceiving himſelf ſuſpended above the earth and carried to a diſtance.

The order of the images and reflections, which paſs through our minds in ſleep, and the laws of their ſucceſſion and connections, are the ſame as when we are awake. We muſt obſerve, however, that theſe internal proceſſes now go on by themſelves, and are not corrected by that reference to external objects, and that exerciſe of the external ſenſes, which takes place in the waking ſtate. Thus we ſee a friend long dead, without being aware that he is not alive; and groſs inconſiſtencies and abſurdities take place without being remarked.

The great activity of the imagination and judgment in the act of dreaming, is evident from the nature of many dreams. "Often," ſays Haller, "in my dreams, I ſeem to read books, printed poems, hiſtories of travels, &c.; and I even ſee the plants of diſtant regions, ſuited to their climates." Others ſolve problems, write, make verſes, &c. The reaſonings which are carried on in ſleep, the ſpeeches which are made, &c. are often more quickly and eaſily performed than when we are awake.

The cauſes of dreams are very obſcure; we cannot determine how the intellectual powers are called into exerciſe, nor what ſtimuli ſhould be applied for that purpoſe. It is known, however, that various bodily derangements have an important influence. The ſtate of the ſtomach, which ſo often acts on the brain, will frequently diſturb our reſt; if a perſon, unaccuſtomed to ſuch indulgence, eat a hearty ſupper, he will experience nightmare, that is, a ſenſe of preſſure about the cheſt, and of ſome moſt dreadful impending danger, without the poſſibility of eſcaping it. When the painful ſenſation is arrived at its height, we awake, and can immediately move. Or the ſame cauſe, inſtead of producing nightmare, may diſtreſs us with terrific dreams, in which dangers aſſail us in every ſhape: we fancy that we cannot eſcape from the intricate paſſages and rooms of a houſe; that we ſhall fall from a precipice, or into a river. In theſe inſtances, too, ſome very ſtrong impreſſion generally rouſes us in a ſtate of great alarm. Inſtances are not wanting of perſons who have determined to remember that the dangers preſented to the mind in dreaming are fallacious, and have recollected this at the time, ſo as to be protected from the alarm, which would otherwiſe have been cauſed. Profeſſor Stewart mentions that Dr. Reid freed himſelf in this way from the diſtreſs of frightful dreams, which had annoyed him for ſome time. The writer of this article has experienced the ſame circumſtance, and Haller mentions a ſimilar fact: "Ita ille, quem diximus, ad vitandas pollutiones voluntatem firmam attuliſſe, expergiſcebat ad ſenſum lubricæ imaginis."

In many bodily diſorders, broken ſleep, and alarming dreams, which make the patient ſtart and awake, are common ſymptoms; ſuch is the caſe in hydrothorax, and diſeaſes of the heart. The delirium of fever is an unnatural activity of the internal faculties, the ſenſes being more or leſs quieſcent, produced by the excitation of the brain, and not differing in its eſſential nature from dreams.

Immediate impreſſions ſometimes influence us during ſleep; children will evacuate their urine on a chamber-pot being put in their hands; and the ſame effect is ſaid to have been produced by putting the hand of a ſleeping child in cold water. The cauſe acts more powerfully than it would in the waking ſtate; and the ſame remark holds good with reſpect to the excretion of the ſeminal ſecretion in ſleep. "Somnium," ſays Haller, "quam ſenſatio fortius eſt, et vehementius animam percellit. Id tribuas ſolitudini, quieti, adtentioni ad unicum objectum. Certe vix unquam ſanus homo ex quacunque libidine ſemen profuderit. In ſomniis id fit, certa quidem ætate, neque fere in ſenis, perfacile in pueris. Sed neque ſenſatio, quæ ſomnii cauſa eſt, aut ſola aut pura menti repreſentatur. Ex lege aſſociationis idearum ad ſimplicem ſtimulum naſcitur idea feminæ pulchræ, amatæ, quam ambias, quæ cedat facilis: accedit lectulus, et omne ſatellitium arcani amoris. Et magis et magis poſt primos ſermones adpropinquat cominus ſperata voluptas, ut viciſſim perinde anxietatis hieroglypha continuo graviora menti incumbunt."

The dreams which occur almoſt nightly in moſt individuals, ſhew the activity of the internal mental operations during ſleep: voluntary motions are leſs commonly performed. Some horſes ſleep ſtanding; and the lower jaw is maintained elevated in us during ſleep. The hand is often raiſed when any ſtimulus is applied to the body, although it may not be ſtrong enough to interrupt ſleep. The fact of children expelling their urine, when the pot is brought to them, has been already noticed. Many perſons laugh, weep, ſigh, and talk in their ſleep: the words are indeed generally indiſtinctly pronounced, and the ſentences incomplete.

The ſleep-walkers differ from theſe only in degree. They execute the voluntary motions, which ariſe out of the mental proceſſes carried on in ſleep. It would be endleſs to recount the particular caſes belonging to this ſubject. It is ſufficient to mention that individuals riſe from bed aſleep, and with their eyes cloſed, and not only walk about the room or houſe, going up or down ſtairs, finding their way readily, and avoiding obſtacles, but paſs ſafely through very dangerous places, as windows, or on the roofs of houſes. They execute, too, ſtill more difficult feats. They dreſs themſelves, go out of doors, light a fire, undreſs and bathe, ſaddle and bridle a horſe, ride, write, make verſes, and execute all the actions of life correctly, and even ſometimes acutely. During this time they are aſleep; the eyes are ſhut, or do not ſee if open; the iris is not irritable. When awakened, which is ſometimes not eaſily effected, they do not remember what they have done.

The proportion of time paſſed in ſleep differs in different individuals, and at different ages. From ſix to nine hours may be reckoned about the average proportion. Men of active minds, whoſe attention is engaged in a ſeries of intereſting employments, ſleep much leſs than the liſtleſs and indolent; and the ſame individual will ſpend fewer hours in this way, when ſtrongly intereſted in any purſuits, than when the ſtream of life is gentle and undiſturbed. The great Frederic of Pruſſia, and John Hunter, who devoted every moment of their time to the moſt active employments of body and mind, generally took only four or five hours ſleep. A rich and lazy citizen, whoſe life is merely a chronicle of breakfaſts, dinners, ſuppers, and ſleep, will ſlumber away ten or twelve hours daily. When any ſubject ſtrongly occupies us, it keeps us awake in ſpite of ourſelves. Theſe phenomena are conſiſtent with what we have already ſaid; the animal organs, when the period of their intermiſſion and repoſe has arrived, are kept in activity by new and unuſual cauſes of excitation, and thus the ordinary period of ſleep may be paſſed over, and its ordinary quantity much diminiſhed. When a perſon, who has thus been kept long awake by the occupation of his mind with important and urgent ſubjects, at laſt falls aſleep, the ſlighteſt irritation calls up in the fancy all the trains of thought which have juſt occupied us, and ſets at work again all the internal machinery which has hardly yet become quiet; the ſleep, under ſuch circumſtances, is imperfect, and much diſturbed by dreaming.

The newly-born child ſleeps moſt of its time; it ſeems to wake merely for the purpoſe of feeding. Some have called fœtal exiſtence a perpetual ſleep; but the animal organs, never having been yet exerciſed, can hardly be ſaid to be in a ſtate of repoſe. See EMBRYO.

For the firſt two or three years, children ſleep more than once in the twenty-four hours. Again; very old perſons ſleep much of their time: in the natural progreſs towards death, the animal faculties are firſt extinguiſhed; accordingly, when they begin to decline in decrepid old age, the periods of their intermiſſion are longer. The celebrated De Moivre, when eighty-three years old, was awake only four hours out of the twenty-four (Hiſt. de l'Acad. des Sc. for 1754); and Thomas Parr at laſt ſlept the greateſt part of his time. Animals which do not prey by night, ſeem to paſs as much time aſleep as awake; that is, they ſleep during the dark, and are awake ſo long as the ſun is above the horizon.

The ſtate of torpidity in which many animals paſs the winter months, cannot properly be called ſleep; it is not a repoſe of the animal organs, conſequent on the fatigue produced by their exerciſe; but is a peculiar condition of the whole frame, affecting the internal as well as the external organs, and cauſed directly by the action of cold.

The exhauſtion of the powers of the animal organs by exerciſe being the determining cauſe of ſleep, it comes on after the cloſe of our daily occupations, when darkneſs neceſſarily cauſes an intermiſſion of labour and a general quiet, which are favourable to repoſe. The number of hours devoted to active occupation, and the time at which diſpoſition to ſleep is felt, are influenced conſiderably by habit: after conſiderable and unuſual exertion, ſleepineſs will be felt in the day-time.

The period of ſleep may be protracted, by unuſual excitation, much beyond the ordinary period; but the effect is loſt after a certain time, and ſleep comes on under circumſtances, which appear at firſt moſt unfavourable to it. An eye-witneſs reported that ſome boys, completely exhauſted by exertion, fell aſleep amid all the tumult of the battle of the Nile; and other inſtances are known of ſoldiers ſleeping amid diſcharges of artillery, and all the tumult of war. Couriers are known to ſleep on horſeback, and coachmen on their coaches. A gentleman who ſaw the fact, reported to the writer of this article, that many ſoldiers in the retreat of ſir John Moore, fell aſleep on the march, and continued walking on. Even ſtripes and tortures cannot keep off ſleep beyond a certain time; but it then indicates the greateſt exhauſtion, and conſequently affords an unfavourable prognoſis. Noiſes at firſt prevent us from ſleeping, but their influence ſoon ceaſes, and perſons reſt ſoundly in the moſt noiſy ſituations. The proprietor of ſome vaſt iron-works, who ſlept cloſe to them, through the inceſſant din of hammers, forges, and blaſt-furnaces, would awake if there was any interruption during the night. And a miller, being very ill and unable to ſleep, when his mill was ſtopped on this account, reſted well and recovered quickly when the mill was ſet a going again.

Great hunger prevents ſleep; and cold affecting a part of the body has the ſame effect. Theſe cauſes operated on the unfortunate women who lived thirty-four days in a ſmall room overwhelmed by ſnow, and with the ſlighteſt ſuſtenance: they hardly ſlept the whole time. (Somis Ragionamento ſopra un fatto avvenuto in Bergemoletto, &c. p. 74.) Indigeſtion, and various bodily affections, produce ſleepleſſneſs. We have already noticed, that all mental occupations attended with intenſe thought, and great intereſt, prevent ſleep; and any great affections of the mind have the ſame effect.

It will eaſily be underſtood that circumſtances oppoſite to thoſe juſt enumerated are favourable to ſleep. Bodily exerciſe with tranquillity of mind, and abſence of all excitation, are the moſt important of theſe. A full repaſt is often followed by ſleep, even in animals, as dogs. The diſtention of the ſtomach excites the circulation, and thus brings on a condition of the brain favourable to ſleep. Various vegetable ſubſtances taken into the ſtomach act on the brain in the ſame way. Intenſe cold, affecting the whole body, exhauſts the animal powers and brings on ſleep, which is ſpeedily fatal. See Cold.

Sleepineſs, when it occurs naturally, after our daily occupations, is marked, firſt, by a ſenſe of muſcular fatigue, particularly in the long muſcles: it may be experienced in various parts, according as they have been more exerciſed. We begin to gape; the intellectual functions languiſh; curioſity is blunted; attention becomes painful; and a great deſire of repoſe is felt over the whole body. The impreſſions on the external ſenſes are indiſtinct; we cannot read well, nor does the memory act with its uſual force or order: an uneaſy ſenſation is perceived in the eye; the upper eye-lid falls in ſpite of every effort to keep it elevated. Now the muſcles of the whole body are more or leſs relaxed: hence the head inclines forwards, and the whole body would come to the ground if the perſon were ſtanding. The ſenſe of hearing ſeems to be ſuſpended laſt; we hear and underſtand the converſation of thoſe near us, when the eyes no longer act. Now the ſucceſſion of our mental operations becomes quite involuntary; and a kind of delirium takes place, in which the trains of thought preſerved in the memory ſucceed according to their natural aſſociations and connections. Theſe operations are then ſuſpended, and ſleep is complete.

Reſpecting the ſtate of the body in ſleep we have very little to add to our general account already given. In complete ſleep the body is perfectly motionleſs; the ſenſes are not affected by their reſpective external objects, unleſs the impreſſions ſhould be ſtrong enough to arouſe us. Hunger and thirſt are not felt; nor are we conſcious of the neceſſity of emptying the bladder or bowels, until the diſtention is ſufficient to waken us. The functions of the organic life go on uninterruptedly; digeſtion, chylification, and the converſion into fæces, abſorption, circulation, reſpiration, nutrition, ſecretion, are all continued. There may be ſome ſlight modifications, but they are unimportant.

After the ſleep has laſted long enough to reſtore the animal powers, we awake, without any change or occurrence which can be ſhewn to affect particularly the brain or other parts, of which the action was ſuſpended by ſleep. We open our eyes, and often rub them. We move the limbs and ſtretch them; and in a few ſeconds we have the full uſe of our ſenſes, intellectual faculties, voice and voluntary muſcles, and they recover their powers of action completely.

There are rare examples of individuals, who have gone on ſleeping for days, weeks, and months: but theſe hiſtories are not accompanied with ſuch particulars as would enable us to judge of the cauſe for ſuch a deviation from the ordinary courſe of nature.

Sleep, *Somnus*, in *Mythology*, the ſon of Erebus and of Night, according to Homer and Heſiod, and the brother of *Mors* or *Death*.

Virgil (Æn. vi. v. 278.) aſſigns to this deity an abode with death, in the ſubterraneous or inviſible world.

Statius and Ovid place the chief reſidence, or great palace of Somnus on our earth, in the country of the Cimmerians; no country agreeing better with ſleep than that which is overſpread with eternal darkneſs. Theb. x. v. 84 to 117. Met. xi. v. 592 to 645.

Dreams were the children of ſleep; Ovid names three of them, *viz.* Morpheus, Phobetor, and Phantaſia.

This deity is moſt commonly repreſented by the artiſts as a ſoft youth, ſtretched at his eaſe on a couch, reſting his head on a lion's ſkin, and ſometimes on a lion; with one arm either a little over or under his head, and the other dropping negligently by the ſide of the couch, and either holding poppies, or a horn with the juice of poppies in it. He is often winged, and much reſembles a little Cupid, from whom he is diſtinguiſhed by the lizard (an animal ſuppoſed to ſleep half the year) placed at his feet. There is ſcarcely any one of the deities that is more fully and particularly deſcribed by the poets than this deity of ſleep. Spence's Polymetis, p. 263, &c.

Sleep *of Plants*, *Somnus Plantarum*, in *Vegetable Phyſiology*, is a term uſed by Linnæus, to expreſs a peculiar ſtate in the conſtitution of many plants during the night, evinced by a change of poſition, generally a drooping, or a folding together, of their leaves or leaflets. Such a change, being occaſioned by the withdrawing of the ſtimulus of light, is probably a ſtate of reſt to their vital functions, and therefore the above term is not ſo hyperbolical as at firſt appears. Linnæus has given a curious treatiſe on this ſubject, in the *Amœnitates Academicæ*, v. 4. 333. The phenomenon itſelf had been noticed long before, by Acoſta and Proſper Alpinus, in the Tamarind-tree; and the latter points out ſeveral parallel inſtances in other leguminous plants with pinnated leaves, natives of Egypt. It is indeed moſt remarkable in ſuch plants. Herbs with ternate leaves, as the Trefoil and *Oxalis*, ſleep with their leaflets folded together in an erect poſture; and Pliny has obſerved that the former of theſe aſſumes that poſition at the approach of ſtorms. Cloudy weather, no doubt, produces this effect, in proportion as the plant is in vigour, and the ſtimulus of preceding ſun-ſhine has been ſtrong. Not that a ceſſation or diminution of heat appears to cauſe the change alluded to; for Linnæus has well remarked, from obſerving ſtove-plants, that ſuch is not the caſe. It is the withdrawing of a conſiderable portion of light. The more young and tender the plant, the more ſenſibly is it affected by this cauſe.

Linnæus has, in the above-mentioned treatiſe, elaborately deſcribed the various poſitions which the leaves of different plants aſſume in their ſleep. In general, it may be remarked that they cover, or fold together, the upper ſurfaces of their leaves, expoſing the under, which latter is almoſt uniformly impatient of light. This is ſo much the caſe, that we cannot but ſuſpect the effect of the returning light upon the backs of ſuch leaves, may be the immediate cauſe of their withdrawing from it, and thus the upper ſurface becomes neceſſarily preſented to its rays.

A ſimilar effect of light is ſeen in many flowers, particularly of the compound tribe. But the expanſion of theſe is regulated by other and more abſtruſe laws, which often limit their changes to certain hours of the day, partly, though not abſolutely, independently of light. Many of the Campion tribe, eſpecially, unroll their delicate petals in an evening only, in a preciſe and determinate manner, not to be attributed either to the preſence or the abſence of light. So the moving-plant, *Hedyſarum gyrans*, performs its curious gyrations with apparently perfect indifference as to the degree of light to which it is expoſed, provided the ſurrounding atmoſphere be warm and ſtill. The cloſing or drooping of flowers, moreover, when it depends only on the diminution of light, generally anſwers an evident ſecondary purpoſe, in ſheltering the organs of impregnation from the injurious effects of rain, or nocturnal dews. But ſuch is ſeldom the caſe with leaves, except incidentally, as in *Lotus ornithopodioides*, which plant firſt led Linnæus to attend particularly to the ſubject before us.

Sleep *of the Soul*, in *Theology*, denotes that inſenſible, unconſcious, and inactive ſtate, into which ſome have ſuppoſed that mankind are removed at death, and in which they remain till the period of the general reſurrection and laſt judgment. The term ſleep has been uſed by way of contradiſtinction to that which has been commonly called the intermediate or ſeparate ſtate. Of the advocates of this opinion, ſome have allowed the eſſential diſtinction between body and ſpirit, and the natural immortality of the human ſoul; ſo that, being a ſubſtance and not a mode, it will go on to exiſt, till by ſome poſitive act of the Creator it is annihilated. They cannot admit the ſuppoſition, that the whole man becomes extinct at death, or that death deſtroys or annihilates the thinking ſubſtance; becauſe, they ſay, the reſurrection on this hypotheſis, will not be a reſurrection, but a creation of a new ſet of beings: if death annihilates us in this ſenſe, there can be no future ſtate; becauſe, a being who has loſt his exiſtence cannot be recovered. Accordingly, they maintain, that what happens to the ſoul at death can be no more than a ſuſpenſion of the exerciſe of its faculties, or an incapacitation, from which it will, by the power of Chriſt, be delivered at the reſurrection: and they allege, that there is an infinite difference between the annihilation of the ſoul at death, and its incapacitation; becauſe, one who believes the former, could not poſſibly entertain the hope of a future ſtate; but one who believes the latter, might reaſonably entertain ſuch a hope. Death, they ſay, is a diſtreſs in which our ſpecies has been involved by extraordinary cauſes, and from which we have obtained the hope of being ſaved by the moſt extraordinary means, *viz.* by the interpoſition of Jeſus Chriſt, who, taking upon him our nature, and humbling himſelf to death, has acquired the power of deſtroying death, and is on this account ſtyled the Saviour of the world. However, moſt of thoſe who deny the notion of an intermediate ſtate of conſcious perception between death and the general reſurrection, reject the ſuppoſition of two diſtinct natures in man, and conſider that principle, which is called the *ſoul*, not as a ſpiritual ſubſtance, but as a quality, or property, either ſuperadded to matter by the creator of our frame, or reſulting from the organization of the human body, and particularly of the brain. See Soul.

Accordingly, they allege, that when the organized ſyſtem, to which the power of thinking, &c. is annexed, on which it depends, and from the organization of which, as ſome maintain, it neceſſarily reſults, is diſſolved by death; all the percipient and thinking powers of man, all his capacities of action, and of ſuffering, or of enjoyment, muſt be extinguiſhed, and ceaſe of courſe. And if the property of thinking neceſſarily attends the property of life, as ſome apprehend, nothing can be requiſite to the reſtoration of all the powers of the man, but the reſtoration of the body (no particle of which can be loſt) to a ſtate of life. Whatever is decompoſed, it is ſaid, may certainly be recompoſed by the ſame Almighty power that firſt compoſed it, with whatever change in its conſtitution, advantageous or diſadvantageous, he ſhall think proper; and then the powers of thinking, and whatever depended upon them, will return of courſe, and the man will be, in the moſt proper ſenſe, the ſame being that he was before. Thoſe who hold this opinion maintain, that, according to the ſcriptures, life and immortality were brought to light by the goſpel of Chriſt, in a ſenſe excluſive of all other teachers, and all other revelations, at leaſt from the birth of Moſes downwards; excluſive, likewiſe, of all information from the light of nature, or the reſult of philoſophical diſquiſition on the ſubſtance or qualities of the human ſoul. They hold, moreover, that the ſentence pronounced upon our firſt parents, imported a total deprivation of life, without any reſerve, or ſaving to the life of the ſoul; and conſequently, that eternal life, or a reſtoration and redemption from the conſequences of this ſentence, was effected for, revealed, conſigned, and inſured to man, in and through Chriſt, and will be accompliſhed in no other way than that ſpoken of by Chriſt and his apoſtles, who, they ſay, have left no room to conclude, that there is a ſeparate or intermediate life for the ſoul, when diſunited from the body.

The learned Dr. Law, biſhop of Carliſle, having, with a particular view to the controverſy concerning the intermediate ſtate, enumerated the ſeveral paſſages both in the Old and New Teſtament, in which the words, that are tranſlated ſoul or ſpirit in our verſion, occur, maintains, that none of them ever ſtand for a purely immaterial principle in man, or a ſubſtance wholly ſeparable from, and independent of, the body; and after examining the account which the ſcriptures give of that ſtate to which death reduces us, he obſerves, that it is repreſented by ſleep, by a negation of all life, thought, or action; by reſt, reſting-place, or home, ſilence, oblivion, darkneſs, deſtruction, or corruption. He adds, that the ſcripture, in ſpeaking of the connection between our preſent and future being, doth not take into account our intermediate ſtate in death; no more than we, in deſcribing the courſe of any man's actions, take in the time he ſleeps: and that, therefore, the ſcriptures, in order to be conſiſtent with themſelves, muſt affirm an immediate connection between death and judgment. As for thoſe texts that are uſually alleged on the other ſide of the queſtion, which he has cited and endeavoured to accommodate to his own opinion, he thinks that they are quite foreign to the point, or purely figurative, or capable of a clear and eaſy ſolution on the principle which he adopts, *viz.* that the times of our death and reſurrection are coincident; and that they cannot be fairly oppoſed to the conſtant, obvious tenor of the ſacred writings. With reſpect to philoſophical arguments, deduced from our notions of matter, and urged againſt the poſſibility of life, thought, and agency, being ſo connected with ſome portions of it as to conſtitute a compound being or perſon, he imagines that they are merely grounded on our ignorance, and that they will equally prove againſt known fact and obſervation, in the production of various animals, as againſt the union of two ſuch heterogeneous principles as thoſe of the ſoul and body are ſuppoſed to be. With reſpect to the conſequences of either opinion, he ſays, that on the one ſide, there is nothing more than a temporary ceſſation of thought, which can hurt nobody, except the ſelf-intereſted papiſt, or the ſelf-ſufficient deiſt; but on the other ſide, there is a manifeſt derogation from, if not a total ſubverſion of, that poſitive covenant, which profeſſes to entitle us to everlaſting life. He adds, that all proper and conſiſtent notions of death, reſurrection, and a future judgment, are confounded, and in fine, all the great ſanctions of the goſpel rendered unintelligible or uſeleſs.

The doctrine of the New Teſtament, ſays another writer againſt a ſeparate ſtate, is that man ſhall become immortal, by the way of a reſurrection of the dead, a reſtoration of the whole man to life; and the New Teſtament is ſo far from acknowledging any intermediate conſciouſneſs in man, between death and the reſurrection, that it always ſpeaks of that interval as a ſleep, which implies a ſuſpenſion of the thinking faculty, a reſt from thoſe labours, which require thought, memory, conſciouſneſs, &c. during which thoſe faculties are uſeleſs.

Beſides, the ſcriptural ſyſtem of immortality ſuppoſes, that man had forfeited his original title to immortality, and would never have received it, but for the interpoſition of a Redeemer. The conſequence of this doctrine is, that between the time of the forfeiture and the actual appearance of the Redeemer, the dead could have life in no ſenſe at all; and that neither before nor after the appearance of the Redeemer, dead men were, or would be reſtored to life, otherwiſe than in the way revealed by him, namely, a reſurrection of the dead.

On the other hand, the advocates of a ſeparate ſtate inſiſt, that the ſoul, being an active, ſimple, uncompounded, immaterial ſubſtance, is immortal in its own nature, and capable of an active and conſcious exiſtence, in a ſtate of diſunion and ſeparation from the body; that this natural capacity of the ſoul was not impaired, or at all affected by any thing that happened upon the tranſgreſſion of our firſt parents; that the death, to which they were condemned, was only the death of the body: hence they infer, that there is, and would have been, a future immortal ſtate of being beyond the preſent life, and (the moral attributes of God preſuppoſed) a juſt retribution therein, independent of the doctrine of a reſurrection of the dead; and that in the interval between death and the general reſurrection, there is an intermediate ſtate, in which the departed ſouls of good men are ſuppoſed to have an imperfect reward, and the ſouls of the wicked an imperfect puniſhment; but that every one, at the period of the reunion of the ſoul and body, and of final judgment, will receive a full and complete recompence for the deeds done in the body.

In proof of this opinion, they allege a variety of paſſages both from the Old and New Teſtament, the principal of which we ſhall here enumerate; ſeveral of which they think cannot be conſiſtently explained on the other hypotheſis. Gen. ii. 7. xv. 15. xxxvii. 35. Exod. iii. 6. 1 Sam. xxviii. 11—19. 1 Kings, xvii. 21, 22. Pſ. xxxi. 5. Eccleſ. iii. 21. xii. 7. Matt. x. 28. xvii. 3. Luke, xvi. 19. xx. 38. xxiii. 43. xxiv. 39. Acts, i. 25. vii. 59. 2 Cor. v. 8. xii. 2. Phil. i. 21—24. 1 Pet. iii. 19. iv. 6. Heb. xi. 40. xii. 23. Rev. vi. 9, 10. xiv. 13.

To theſe authorities of ſcripture, they add the teſtimony of the fathers of the church, who lived in or near the time of the apoſtles, who are ſaid to be unanimous in this opinion, and perſuaded that the ſoul of every man upon the diſſolution of the body died not, but had a proper place to go to, and that accordingly this doctrine is to be found in the moſt ancient Chriſtian liturgies.

Great ſtreſs has been laid, in this controverſy, on the meaning of the term death, as it occurs in ſcripture, and particularly in the ſentence denounced againſt the firſt parent of the human race. (See DEATH, in *Theology*.) The biſhop of Carliſle obſerves, that the word *death*, in its original and obvious ſenſe, implies a ceſſation of all natural life, or a real diſſolution and deſtruction of the whole man. But Mr. Farmer, a well-known and excellent writer, in the introduction to his learned work of the "General Prevalence of the Worſhip of Human Spirits, &c." 1783, has taken ſome pains to aſcertain the meaning of the word *death*, in the threatening denounced againſt Adam. To this purpoſe, he ſays, that if human ſpirits were worſhipped in the age of Moſes, particularly in Egypt and Phœnicia, the word death could not at that time, and in thoſe countries, denote more than the deſtruction of bodily life; for, if this term had farther included in it the inſenſibility or extinction of the ſoul, the dead would not have been honoured as gods. And if Moſes had uſed it in this extenſive ſenſe, he would have been miſunderſtood by the Egyptians, who aſſerted the immortality of the ſoul, and by the Hebrews, who dwelt among them, and had adopted their ſyſtem of religion.

This learned writer, in confirmation of this interpretation of death, obſerves, that although one great deſign of Moſes, in giving an account of the introduction of death into the world, was to guard againſt the worſhip of departed ſpirits, and though nothing could have anſwered this deſign more effectually than repreſenting the ſoul of Adam as a mere quality, or as the reſult of the peculiar ſtructure and organization of his body, yet, ſo far is he from ſuppoſing this to be the caſe, that according to him, after the body of the firſt man was perfectly organized by the immediate hand of the Almighty, he did not become a living ſoul or perſon, till God breathed into his noſtrils the breath of life; a principle diſtinct from the duſt out of which his body was formed, and, therefore, capable of ſubſiſting in a ſtate of ſeparation from it. Nor does Moſes uſe the ſame language in relating the formation of any other living creatures; which proves that the principle of life in man is of a ſuperior kind to that in brutes.

Beſides, the ancient patriarchs did not believe that the ſoul of man periſhed with his body. Agreeably to the moſt ancient opinion concerning departed ſpirits, the ſacred writers ſuppoſed the ſouls of the dead to exiſt in *ſheol*, or *hades*, a place inviſible to human ſight, and that, in the diſtribution of them, regard was had to the former relation in which they ſtood to one another. Moreover, Moſes himſelf believed the ſeparate ſubſiſtence of the ſoul, and has even given it a divine ſanction. Gen. xv. 15.

Nor do any of the ſacred writers ever deſcribe death in terms different from thoſe uſed by perſons, who certainly acknowledged the continuance of the ſoul after it.

Sleep, by which it is deſcribed, is not a ſtate of nonexiſtence, but of reſt; and it is well known, that this ſoft image of death was commonly uſed to expreſs the thing itſelf, by thoſe who aſſerted the exiſtence of ſouls in hades. Silence, oblivion, darkneſs, and corruption, by which the ſtate of the dead is deſcribed, refer only to the body, or to the ſuppoſed ſtate of the ſoul, while it was in ſheol, and are not peculiar to the ſacred writers, but were common in all countries, where both the popular belief, and the eſtabliſhed worſhip, were inconſiſtent with the notion of the ſoul's periſhing with the body.

And many of the terms, by which death was deſcribed in all countries, clearly imply, and are built upon, a belief of the diſtinction between ſoul and body, and of their being ſeparated at death.

According to the Greeks, to die was to depart, to go away; and the writers of the New Teſtament deſcribe death by a departure, (Luke, ix. 31.) that is, of the ſoul from the body to another ſtate. To all which it may be added, that the Jews, from the time of their return from Babylon, aſſerted the ſeparate exiſtence of the ſoul after death; as appears from their imitation of the heathen idolatry, from their evocation of the dead, and from the early references in ſcripture to the receptacle of departed ſouls, and many other proofs. This was the opinion, not only of a few eminent individuals, ſuch as Philo, but of the learned ſects, the Eſſenes and Phariſees, and of the whole body of the people, almoſt without exception, in the time of our Saviour. To this principle the Phariſees, whoſe doctrine formed the popular creed, added another, *viz.* the reſurrection of the dead. The Sadducees believed the extinction of the ſoul at death, but did not admit the reſurrection; the Phariſees, on the other hand, admitted the latter and denied the former. By the term reviviſcence, or return to life, by which the reſurrection is deſcribed, the Jews could not mean creating anew the ſoul, that had been deſtroyed, becauſe, if it were poſſible, they did not allow that the former ſoul periſhed at death. Nor did they believe, that man had no ſoul; and, therefore, that his reſurrection conſiſted in the re-organization of his former body, or in furniſhing him with a new body, organized as that was; becauſe this is a flat contradiction to their belief of the diſtinction between ſoul and body, and the ſeparate exiſtence of the former. What then did they, or could they mean by the reſurrection to life, but the reſtoration of that kind of life which they had loſt, by the reunion of their ſouls to a human body, either the ſame which they had before, or one in effect the ſame? In virtue of this reunion, the *dead* man became a *living* man, the ſame as he was before he died, with the ſame conſciouſneſs and recollection, the principle of conſciouſneſs having never periſhed. And if, in or near the time of Chriſt, the terms reſurrection, reviviſcence, or living again, as uſed both by Jews and Gentiles, denoted the reunion of a ſoul to a human body, the ſame terms, when adopted by Chriſt and his apoſtles, muſt have the ſame meaning: and every one would underſtand them in their common and ordinary ſignification. Conſequently, if life, as expreſſing the reſurrection, ſignifies the ſoul's return to a human body, death, its oppoſite, denotes its ſeparation; both terms imply the continuance of the ſoul after death: a principle, ſays Mr. Farmer, held in the moſt ancient times, by Heathens and Jews, by patriarchs and prophets, and by the people, particularly in the times of Moſes and the Meſſiah, and which gives great probability to the doctrine of a reſurrection.

The advocates of the ſleep of the ſoul, on the other hand, earneſtly contend, that it was the opinion of the apoſtles and early Chriſtians, that, whatever be the nature of the ſoul, its percipient and thinking powers ceaſe at death; and that they had no hope of the reſtoration of thoſe powers, but in the general reſurrection of the dead.

Dr. Campbell, in his "Preliminary Diſſertations," (Part ii.) has introduced ſome remarks, that deſerve attention, on the controverſy concerning an intermediate ſtate between death and the reſurrection. He obſerves, *firſt*, that the arguments, on which the deniers of that ſtate chiefly build, ariſe, in his opinion, from a miſapprehenſion of the import of ſome ſcriptural expreſſions. Καθευδειν, *κοιμαν*, *to ſleep*, are often applied to the *dead;* but this application is no more than a metaphorical euphoniſm, derived from the reſemblance which a dead body bears to the body of a perſon aſleep. Traces of this idiom may be found in all languages, whatever be the popular belief about the ſtate of the dead. They often occur in the Old Teſtament; yet it has been ſhewn, that the common doctrine of the Orientals favoured the ſeparate exiſtence of the ſouls of the deceaſed. But if it did not, and if, as ſome ſuppoſe, the ancient Jews were, on all articles relating to another life, no better than Sadducees, this ſhews the more ſtrongly, that ſuch metaphors, ſo frequent in their writings, could be derived ſolely from bodily likeneſs, and having no reference to a reſurrection, could be employed ſolely for the ſake of avoiding a diſagreeable or ominous word. It is acknowledged, at the ſame time, that Chriſtians have been the more ready to adopt ſuch expreſſions, as their doctrine of the reſurrection of the body, preſented to their minds an additional analogy between the bodies of the deceaſed and the bodies of thoſe aſleep, that of being one day awaked. But our author ſees no reaſon to imagine that, in this uſe, they carried their thoughts further than to the corporeal and viſible reſemblance now mentioned. Another miſtake about the import of ſcriptural terms, is in the ſenſe which has been given to the word *αναςάσις*. They confine it, by a uſe derived merely from modern European tongues, to that renovation which we call the reunion of the ſoul and the body, and which is to take place at the laſt day. But this is not always the ſenſe of the term in the New Teſtament.

Dr. Campbell remarks, *ſecondly*, that many expreſſions of ſcripture, in the natural and obvious ſenſe, imply that an intermediate and ſeparate ſtate of the ſoul is actually to ſucceed death. Such are the words of our Lord to the penitent thief upon the croſs (Luke, xxiii. 43.); Stephen's dying petition (Acts, vii. 59.); the compariſons which the apoſtle Paul makes in different places (2 Cor. v. 6, &c. Philip. i. 21.) between the enjoyment which true Chriſtians can obtain by their continuance in this world, and that on which they enter at their departure out of it, and ſeveral other paſſages. Let the words referred to be read by any judicious perſon, either in the original, or in the common tranſlation, which is ſufficiently exact for this purpoſe, and let him, ſetting aſide all theory or ſyſtem, ſay candidly, whether they would not be underſtood, by the groſs of mankind, as preſuppoſing that the ſoul may and will exiſt ſeparately from the body, and be ſuſceptible of happineſs or miſery in that ſtate. If any thing could add to the native evidence of the expreſſions, it would be the unnatural meaning that is put upon them, in order to diſguiſe that evidence. The apoſtle Paul, they are ſenſible, ſpeaks of the ſaints as admitted to enjoyment in the preſence of God, immediately after death. Neverthelcſs, in order to palliate the direct contradiction this bears to their doctrine, that the vital principle, which is all they mean by the ſoul, remains extinguiſhed between death and the reſurrection, they remind us of the difference between abſolute or real, and relative or apparent, time. They admit that, if the apoſtle be underſtood as ſpeaking of real time, what is ſaid flatly contradicts their ſyſtem: but they ſay, his words muſt be interpreted as ſpoken only of apparent time. He talks indeed of entering on a ſtate of enjoyment, immediately after death, though there may be many thouſands of years between the one and the other: for he means only, that when that ſtate ſhall commence, however diſtant in reality the time may be, the perſon entering on it will not be ſenſible of that diſtance, and conſequently there will be to him an apparent coincidence with the moment of his death. But, ſays Campbell, does the apoſtle any where give a hint that this is his meaning? or, is it what any man would naturally diſcover from his words? Did the ſacred penman, then, as our author proceeds, mean to put a cheat upon the world, and, by the help of an equivocal expreſſion, to flatter men with the hope of entering, the inſtant they expire, on a ſtate of felicity; when, in fact, they knew that it would be many ages before it would take place? But, were the hypotheſis about the extinction of the mind between death and the reſurrection well founded, the apparent coincidence they ſpeak of is not ſo clear as they ſeem to think it.

Our author remarks, *thirdly*, that even the various equivocation, (or, perhaps, more properly, mental reſervation,) that has been deviſed for them, will not, in every caſe, ſave the credit of apoſtolical veracity. The words of Paul to the Corinthians are, "Knowing, that whilſt we are at home in the body, we are abſent from the Lord." Again: "We are willing rather to be abſent from the body, and preſent with the Lord." Could ſuch expreſſions have been uſed by him, if he had held it impoſſible to be with the Lord, or indeed any where, without the body; and that, whatever the change was which was made by death, he could not be in the preſence of the Lord, till he returned to the body? Abſence from the body, and preſence with the Lord, were never, therefore, more unfortunately combined, than in this illuſtration. Things are combined here as coincident, which, in the hypotheſis of thoſe gentlemen, are incompatible. If recourſe be had to the original, the expreſſions in Greek are, if poſſible, ſtill ſtronger. They are, οι ενδημȣντες εν τω σωματι, *thoſe who dwell in the body*, who are εκδημȣντες απο τȣ Κυριȣ, *at a diſtance from the Lord;* as, on the contrary, they are οι εκδημȣντες εκ τȣ σωματος, *thoſe who have travelled out of the body*, who are οι ενδημȣντες προς τον Κυριον, *thoſe who reſide*, or *are preſent with the Lord.* In the paſſage to the Philippians alſo, the commencement of his preſence with the Lord is repreſented as coincident, not with his return to the body, but with his leaving it, with the diſſolution, not with the reſtoration, of the union. We may here ſubjoin an inquiry, how the apoſtle could be *in a ſtrait betwixt two* (Philip. i. 23.), that of *living in the fleſh*, and *being with Chriſt*, which he pronounces to be *far better*, if the exerciſe of his powers of ſervice and capacity of enjoyment ceaſed at death. A mind like his could not heſitate between living in the fleſh, and thus ſerving the Chriſtian cauſe, and ſinking at death into a ſtate of total inaction, and of thus continuing for a long but indefinite period.

The *fourth* remark made by Dr. Campbell on this ſubject is, that from the turn of the New Teſtament, the ſacred writers appear to proceed on the ſuppoſition, that the ſoul and the body are naturally diſtinct and ſeparable, and that the ſoul is ſuſceptible of pain or pleaſure in a ſtate of ſeparation. It were endleſs to enumerate all the places which evince this. The ſtory of the rich man and Lazarus (Luke, xvi. 22, 23.); the laſt words of our Lord upon the croſs (Luke, xxiii. 46.), and of Stephen when dying; Paul's doubts, whether he was in the body or out of the body, when he was tranſlated to the third heaven and paradiſe (2 Cor. xii. 2, 3, 4.); our Lord's words to Thomas, to ſatisfy him that he was not a ſpirit (Luke, xxiv. 39.); and the expreſs mention of the denial of ſpirits, as one of the errors of the Sadducees (Acts, xxiii. 8.): theſe are irrefragable evidences of the general opinion on this ſubject, both of Jews and Chriſtians. By *ſpirit*, it is obſerved, as diſtinguiſhed from *angel*, is evidently meant the departed ſpirit of a human being; for that man is here, before his natural death, poſſeſſed of a vital and intelligent principle, which is commonly called his ſoul or ſpirit, it was never pretended that they denied. It has been ſaid, that this manner of expreſſing themſelves has been adopted by the apoſtles and evangeliſts, merely in conformity to vulgar notions. To me, ſays Dr. Campbell, it appears a conformity, which (if the ſacred writers entertained the ſentiments of our antagoniſts in this article) is hardly reconcileable to the known ſimplicity and integrity of their character.

Before the council of Florence, held in 1439, under pope Eugenius IV., the ancient doctrine, both of the Greek and Latin churches, is ſaid to have been, that the ſouls of the ſaints were in *abditis receptaculis*, or in *exterioribus atriis*, where they expected the reſurrection of their bodies, and the glorification of their ſouls; and though the fathers believed all of them to be happy, yet they did not think they would enjoy the beatific viſion before the reſurrection. But in this council it was decreed, that the ſouls of thoſe, who, after baptiſm, have incurred no ſtain of ſin, and alſo thoſe ſouls, which having contracted the ſtain of ſin, whether in their bodies or diveſted of their bodies, have been purged by the ſacrifice of the maſs, prayer, and alms, are received into heaven immediately, &c.

In the Lateran council, held under Leo X., in 1513, it was decreed, that the ſoul is not only truly, and of itſelf, and eſſentially the form of the human body, as is expreſſed in the canon of pope Clement V., publiſhed in the general council of Vienne, but likewiſe immortal, and according to the number of bodies into which it is infuſed, is ſingularly multipliable, multiplied, and to be multiplied.

However, Peter Pomponatius, a philoſopher of Mantua, publiſhed a book in 1516, on the immortality of the ſoul, in which, after ſtating the moral arguments againſt the mortality of the ſoul, and endeavouring to ſhew that they are weak and inconcluſive, infers upon the whole, that the immortality of the ſoul, being a problematical queſtion, we can have no aſſurance of it but from revelation; and that they who would build immortality upon any other foundation, only verify the character given to certain ſelf-ſufficient reaſoners by the apoſtle, *viz.* profeſſing themſelves wiſe, they became fools.

In 1520, Luther, in the defence of his propoſitions, which had been condemned by a bull of Leo X., ranks the natural immortality of the ſoul among the monſtrous opinions of Popery; and he afterwards made uſe of the doctrine of the ſleep of the ſoul as a confutation of purgatory and ſaint-worſhip, and he is ſaid to have continued in that belief to the laſt moment of his life.

William Tyndall alſo, the famous tranſlator of the bible into Engliſh, in defending Luther's doctrine againſt ſir Thomas More's objections, conſiders the ſleep of the ſoul as the doctrine of the Proteſtants in his time, and founded on the ſcriptures: though, in conſequence of the oppoſition given to this doctrine by Calvin, in his Pſychopannychia, publiſhed in 1534, and the turn hereby given to the ſentiments of the Reformed in general, he ſeems to have recanted his opinion. Calvin, however, ſeems to have been embarraſſed with the ſouls of the wicked, and ſays, he would only be reſponſible for the faithful.

The firſt expreſs condemnation of the doctrine of the ſleep of the ſoul, in a Proteſtant confeſſion, occurs in the fortieth of king Edward's Articles, compoſed in 1552.

After the long prevalence of the doctrine of the intermediate ſtate, that of the ſleep of the ſoul has of late years been revived, and, as one of its zealous advocates affirms, gains ground, not ſo much from conſiderations of philoſophy, as from a cloſe attention to the ſenſe of the ſcriptures.

We ſhall cloſe this article with obſerving, that a ſingular hypotheſis was advanced a few years ago by Dr. Caleb Fleming, and of late vindicated by an anonymous writer; and this is, that the reſurrection takes place immediately after death. On this ſubject, ſee Law's Appendix and Poſtſcript to his Conſiderations on the Theory of Religion, &c. 1774. Hiſtorical View of the Controverſy concerning an intermediate State, &c. 1772. Prieſtley's Diſquiſitions on Matter and Spirit, 1777. Correſpondence between Dr. Price and Dr. Prieſtley, 1778; and the publications of Steffe, Warburton, Goddard, Coward, Peckard, Jortin, &c. on both ſides of the queſtion, cited by the author of the Hiſtorical View, &c. Fleming's Search after Souls.

SLEEPERS, in *Natural Hiſtory*, a name given to ſome animals which ſleep all the winter: ſuch as bears, marmots, dormice, bats, hedge-hogs, &c. Theſe do not feed in winter, have no ſenſible evacuations, breathe little, or not at all, and moſt of the viſcera ceaſe from their functions. Some of theſe creatures ſeem to be dead, and others to return to a ſtate like unto that of the fœtus before birth. In this condition they continue, till by length of time maturating the proceſs, or by new heat, the fluids are attenuated, the ſolids ſtimulated, and the functions begin where they left off. See Dr. Stevenſon in Med. Ed. Edinb. vol. v. art. 177. See MIGRATION.

SLEEPER, in *Building*, a name uſed for the oblique rafter, that lies in a gutter.

SLEEPERS, in the *Glaſs Trade*, are the large iron bars croſſing the ſmaller ones, and hindering the paſſage of the coals, but leaving room for the aſhes.

SLEEPERS, in the *Military Art*. See PLATFORM.

SLEEPERS, in *Ship-Building*, pieces of long compaſs-timber, fayed and bolted diagonally upon the tranſoms and timbers adjoining withinſide, to ſtrengthen the buttock of the ſhip. There are from two to three pairs.

SLEEPY CREEK, in *Geography*, a river of America, in North Carolina, which runs into the Atlantic, N. lat. 34° 43′. W. long. 76° 44′.

SLEETS, in *Gunnery*, are the parts of a mortar, paſſing from the chamber to the trunnions, for ſtrengthening that part.

SLEEVE, HIPPOCRATES's. See HIPPOCRATES.

SLEIDAN, JOHN, in *Biography*, a celebrated hiſtorian, was born in 1506 at Sleidan, a ſmall town at Cologne. His origin, it has been inferred, was obſcure, becauſe he took no other name than that of the town in which he was born. He received the early part of his education in his native country, and then went to Paris, whence he removed to Orleans, in order that he might ſtudy the law as a profeſſion. On his return to Paris, he was recommended by his countryman and ſchool-fellow, J. Sturmius, to cardinal archbiſhop du Bellay, who obtained for him a penſion, and initiated him into the routine of public buſineſs. In 1542 he was obliged, owing to his attachment to the reformed religion, to retire to Straſburg. He was at firſt a follower of Zuingle, but he afterwards joined the Lutherans, and became a conſiderable writer in their defence. He was alſo entruſted with employments of conſiderable importance to the welfare of the party which he had joined. In 1545 he was deputed to the king of England; and in 1551 he was one of the Proteſtant envoys to the council of Trent, which, however, was ſoon diſſolved by the troops of Maurice, elector of Saxony. The death of his wife, which happened in 1555, threw him into a deep melancholy, which had the calamitous effect of obliterating his memory to ſuch a degree, that he did not know even his own children. He died at Straſburg, in the following year. He is chiefly known as an author by a work, entitled "De Statu Religionis et Reipublicæ Carolo Quinto Cæſare, Commentaria, Lib. XXV." which was firſt publiſhed in 1555. It comprehends the hiſtory of his own times, from 1517 to the year of its publication, and has always been in great credit among the Proteſtants; though it has been charged with partiality by Catholic writers, and by the adherents of the emperor Charles. "Much of it," ſays his biographer, "is extracted from public records, and from the archives of the city of Straſburg, with which he was furniſhed by his friend J. Sturmius." De Thou ſpeaks of it as a work drawn up "exacta fide et diligentia," and he praiſes very highly the writer's learning and talents for buſineſs. This work has been tranſlated into ſeveral modern languages: the French verſion was made by Le Courayer. Another celebrated work of Sleidan's is a compendium of ancient hiſtory, entitled "De quatuor Summis Imperiis, Lib. tres," which has gone through a great number of editions. He publiſhed likewiſe a Latin tranſlation of the Hiſtory of Philip de Comines, and an abridgment of that of Froiſſart, beſides verſions of other works on general hiſtory and politics.

SLEKTENES, in *Geography*, a ſmall iſland in the North ſea, near the coaſt of Lapland. N. lat. 70° 25′.

SLEMISH, or SLENISH, a mountain of the county of Antrim, Ireland, near the centre, and forming a very conſpicuous object from moſt parts of the county. Dr. Richardſon calls it a round *hummock*, formed by an accumulation of rectilineal baſaltic ſtrata of ſteady parallelism. The height, as meaſured by the barometer, is 1398 feet. See HUMMOCK.

SLESWICK, *Duchy of*, ſometimes called South Jutland, (ſee DENMARK and JUTLAND,) a province of Denmark, bounded on the north by Jutland, on the eaſt by the Baltic, on the ſouth by the duchy of Holſtein, and on the weſt by the North ſea; about 72 miles in length, and from 30 to 56 in breadth, without including ſeveral iſlands on the coaſt. The country is well ſupplied with corn, cattle, and fiſh; it has no mountains, and but few eminences that deſerve the name of hills. The ſoil is, in general, well cultivated, and agriculture is much encouraged by the crown. Sleſwick has from time immemorial been united to Denmark, but has ſometimes been given to a brother of the reigning king, as a fief; but this grant has produced conſiderable diſputes, more eſpecially in the laſt century, when the duke in poſſeſſion attempted to become an independent prince. In 1720 it was recovered to the crown. The adminiſtration is veſted in a governor, chancellor, vice-chancellor, and counſellors: the governor reſides at Gottorp. The inhabitants are a mixture of Danes, Saxons, Friſchians, and Hollanders, who reſpectively ſpeak their own languages. The prevalent religion is Lutheran. This duchy contains ſeveral towns, and 1500 villages.

SLESWICK, the capital of the above duchy, ſituated on the river or gulf of Sley; formerly called "Hetheby," from queen Hetha, who was the founder. After having undergone a variety of viciſſitudes, it is now no longer a port, the Sley being choaked up with ſand. It is an irregular town of great length, and contains about 5630 inhabitants. The houſes are conſtructed with brick, and in neatneſs and manner of building reſemble thoſe of Holland; the inhabitants are alſo the Dutch, and many of them ſpeak their tongue, though the uſual languages are the German and the Daniſh. Cloſe to Sleſwick is the old palace of Gottorp, which is a large brick edifice, ſurrounded with a rampart and moat. It was formerly the ducal reſidence, and more lately inhabited by the ſtadtholder or governor, prince Charles of Heſſe Caſſel, who married Louiſa, princeſs of Denmark. From this caſtle the ducal line, formed by Adolphus, ſon of Frederic I. king of Denmark, was denominated Holſtein-Gottorp, which ſtill ſubſiſts in the perſon of the great duke of Ruſſia; 60 miles N. of Hamburg. N. lat. 54° 33′. E. long. 9° 34′.

SLETDALER, or *Baſe Rixdollar*, in *Commerce*, a money of account in Denmark, reckoned at 4 marks, or 64 ſkillings Daniſh.

SLICES, in *Ship-Building*, tapering pieces of plank, uſed to drive between the timbers before planking, as now practiſed in the navy, for ſetting up a ſhip on her ways for launching, &c.

SLICH, in *Metallurgy*, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

The manner of preparing the ſlich at Cremnitz, in Hungary, is this: they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are four-and-twenty beams, armed at their bottoms with iron; theſe, by a continual motion, beat and grind the ore, till they reduce it to powder: during all this operation, the ore is covered with water. There are four wheels uſed to move theſe beams, each wheel moving ſix; and the water, as it runs off, carrying ſome of the metalline particles with it, is received into ſeveral baſons, one placed behind another; and finally, after having paſſed through them all, and depoſited ſome ſediment in each, it is let off into a very large pit, of almoſt half an acre of ground; in this it is ſuffered to ſtand ſo long, as to depoſit all its ſediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away, and replaced by more, as often as occaſion requires. That ore which lies next the beams, where it was pounded, is always the cleaneſt or richeſt.

When the ſlich is waſhed as much as they can, a hundred weight of it uſually contains about an ounce, or perhaps but half an ounce of metal; which is not all gold, for there is always a mixture of gold and ſilver, but the gold is in the largeſt quantity, and uſually is two-thirds of the mixture: they then put the ſlich into a furnace with ſome lime-ſtone, and ſlaken, or the ſcoria of former meltings, and run them together. The firſt melting produces a ſubſtance, called *lech;* this lech they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *roſt;* to this roſt they add ſand in ſuch quantity as they find neceſſary, and then melt it over again.

They have at Cremnitz many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always neceſſary, after the before-mentioned proceſſes. See GOLD.

SLICKENBORCH, in *Geography*, a town of Holland, in the ſtate of Frieſeland, on the river Linde, at its union with the Kuynder; 28 miles S. of Lewarden.

SLICKENBURG, a ſmall iſland near the N.W. coaſt of Borneo. N. lat. 3° 59′. E. long. 112° 31′.

SLIDE-*Butt*, in *Agriculture*, a ſort of ſledge contrived in the form of a ſtrong, oblong box, and ſhod underneath with ſtrong, rough, thick pieces of timber. It is capable of holding about three or four common wheel-barrows full of earth or compoſt. In Cornwall and other hilly diſtricts, it is found uſeful and convenient for drawing out dung and other dreſſings to ſmall diſtances from the large heaps depoſited in the fields or other places. They are uſed with one or two oxen or horſes for the moſt part. They have ſometimes alſo low wheels, when they are denominated gurry butts in the above county.

SLIDE-*Rails*, or *Guard-Rails*, in the conſtruction of *Canals*, are long pieces of timber fixed to piles or plugs in the face of the walls of locks, bridges, tunnels, &c. generally a little above the ſurface of the water, to prevent boats from ſtriking and injuring the walls.

SLIDING, in *Mechanics*, *Superinceſſus radens*, is, when the ſame point of a body, moving along a ſurface, deſcribes a line on that ſurface.

Such is the motion of a parallelepiped, protruding along a plane.

SLIDING-*Rule*, a mathematical inſtrument, ſerving to work queſtions in gauging, meaſuring, &c. without the uſe of compaſſes; merely by the ſliding of the parts of the inſtrument one by another, the lines and diviſions of which give the anſwer, by inſpection.

This inſtrument is variouſly contrived, and applied by various authors, particularly Everard, Coggeſhall, Gunter, Hunt, and Partridge; but the moſt uſual and uſeful ones are thoſe of Everard and Coggeſhall; the deſcription and uſes of which are as follow.

SLIDING-*Rule, Everard's*, is principally uſed in gauging; being ordinarily made of box, a foot long, an inch broad, and $\frac{6}{10}$ths of an inch thick. It conſiſts of three parts: a rule, on each ſide of which, *a b* and *c d* (*Plate* VII. *Surveying*, *fig.* 4.) is a groove, and two ſmall ſcales, or ſliding-pieces, *m*, *n*, ſlide in the grooves. When both theſe pieces are drawn out to their full extent, the inſtrument is three feet long.

On the firſt broad face of the inſtrument, *a b*, are four lines of numbers; for the properties, &c. of which, ſee GUNTER'S *Line*. The firſt, marked A, conſiſting of two radiuſes numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 1; and then 2, 3, 4, 5, &c. to 10. On this line are four braſs centre-pins, two in each radius; one in each of which is marked M B, to ſignify that the number it is ſet againſt, 2150.42, is the number of cubic inches in a malt-buſhel; the other two are marked with A, to ſignify that the numbers they are ſet againſt, *viz.* 282, are the cubic inches in an ale-gallon. The ſecond and third lines of numbers are on the ſliding-pieces, and are exactly the ſame with the firſt. They are diſtinguiſhed by the letter B. Cloſe to the figure 7, in the firſt radius, is a dot, marked S *i*, ſet exactly over .707, denoting .707 to be the ſide of a ſquare inſcribed in a circle, whoſe diameter is unity. Cloſe to 9 is another dot, marked S *e*, ſet over .886, which is the ſide of a ſquare equal to the area of a circle, whoſe diameter is unity. Another dot, near W, is ſet over 231, the number of cubic inches in a wine-gallon; and another, near C, is ſet over 3.14, the circumference of a circle, whoſe diameter is unity. The fourth line of numbers, marked M D, to ſignify *malt depth*, is a broken line of two radiuſes, numbered 2, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, 9, 8, 7, &c. the number 1 being ſet directly againſt M B on the firſt radius.

On the ſecond broad face, marked *c d*, are 1. A line of numbers of one radius, numbered 1, 2, 3, &c. to 10, noted by the letter D. On this are four centre-pins; the firſt, marked W G, is the gauge-point for a wine-gallon, *i. e.* the diameter of a cylinder, whoſe height is an inch, and content 231 cubic inches, or a wine-gallon, which is 17.15 inches: the ſecond centre-pin, A G, ſtands at the gauge-point for an ale-gallon, which is 18.95 inches. The third, M S, ſtands at 46.3, the ſide of a ſquare, whoſe content is equal to the inches in a ſolid buſhel. The fourth, M R, is the gauge-point for a malt-buſhel, which is 52.32 inches. 2. Two lines of numbers on the ſliding-piece, which are exactly the ſame as thoſe on the ſliding-piece on the other ſide, called C. Cloſe to the diviſion 8 is a dot, marked *c*, which is ſet to .795, the area of a circle, whoſe circumference is unity; and another, marked *d*, ſtands at .785, the area of a circle, whoſe diameter is unity. 3. Two lines of ſegments, each numbered 1, 2, 3, to 100; the firſt, for finding the ullage of a caſk, taken as the middle fruſtum of a ſpheroid, lying with its axis parallel to the horizon; and the other for finding the ullage of a caſk ſtanding.

Again, on one of the narrow ſides, noted *e*, are, 1. A line of inches, numbered 1, 2, 3, &c. to 12, each ſubdivided into ten equal parts. 2. A line, by which, with that of inches, we find a mean diameter for a caſk, in the figure of the middle fruſtum of a ſpheroid: it is numbered 1, 2, 3, &c. to 7, and marked *ſpheroid*. 3. A line for finding the mean diameter of a caſk, in the figure of the middle fruſtum of a parabolic ſpindle, which gaugers call the *ſecondary variety of caſks;* it is numbered 1, 2, 3, &c. and noted *ſecond variety*. 4. A line, by which we find the mean diameter of a caſk of the third variety, *i. e.* of a caſk in the figure of two parabolic conoids, abutting on a common baſe; it is numbered 1, 2, 3, &c. and noted *third variety*.

On the other narrow face, marked *f*, are, 1. A foot divided into 100 equal parts, marked F M. 2. A line of inches, like that before-mentioned, noted I M. 3. A line for finding the mean diameter of a fourth variety of caſks, which is the middle fruſtum of two cones, abutting on a common baſe. It is numbered 1, 2, 3, &c. and noted F C, ſignifying fruſtum of a cone.

On the back ſide of the two ſliding-pieces is a line of inches, from 13 to 36, when the two pieces are put endwiſe; and againſt that, the correſpondent gallons, or hundred parts, that any ſmall tub, or the like open veſſel (from 13 to 36 inches diameter), will contain at one inch deep.

Mr. Overley, and other writers on this ſubject, have ſuggeſted ſome improvements in the conſtruction of this inſtrument. See Overley's Young Gauger's Inſtructor, p. 108.

SLIDING-*Rule, Uſe of Everard's*.—1. To multiply one number by another. Suppoſe 4 required to be multiplied by 6: ſet 1 on the line of numbers B, to 4 on the line A; then, againſt 6 upon B is 24, the product ſought upon A. Again, to multiply 26 by 68, ſet 1 on B to 26 on A; then, againſt 68 on B is 1768 on A, the product ſought.

2. To divide one number by another. Suppoſe 24 to be divided by 4: ſet 4 on B to 1 on A; then againſt 24 on B is 6 on A, which is the quotient. Again, to divide 952 by 14; ſet 14 on A to 1 on B, and againſt 952 on A, you have, on B, 68, which is the quotient.

3. To work the rule of three. If 8 gives 20, what will 22 give? Set 8 on B to 20 on A, then againſt 22 on B ſtands 55 on A, the number ſought.

4. To find a mean proportional between two numbers, ſuppoſe between 50 and 72: ſet 50 on C to 72 on D; then againſt 72 on C you have 60 on D, which is the mean required.

5. To extract the ſquare root of a number. Apply the lines C and D to one another, ſo that 10 at the end of D be even with 10 at the end of C; then are theſe two lines a table, ſhewing the ſquare root of any number leſs than 1000000 by inſpection: for againſt any number on C, the number anſwering to it on D is the ſquare root of it.

Note, if the given number conſiſts of 1, 3, 5, or 7 places of integers, ſeek it on the firſt radius, on the line C, and againſt it is the root required at D.

6. Either the diameter or circumference of a circle, being given, to find the other. Set 1 on the line A againſt 3.141 (to which is written C) on the line B; and againſt any diameter on the line A, you have the circumference on B, and contrariwiſe: thus, the diameter being 20 inches, the circumference will be 62.831 inches; and the circumference being 94.247, the diameter will be 30.

7. The diameter of a circle given, to find the area in inches, or in ale or wine-gallons. Suppoſe the diameter 20 inches, what is the area? Set 1 upon D, to .785 (noted *d*) on C; then againſt 20 on D is 314.159, the area required. Now, to find that circle's area in ale-gallons, ſet 18.95 (marked A G) upon D, to 1 on C; then againſt the diameter 20 upon D, is the number of ale-gallons on C, *viz.* 1.11. The ſame may ſerve for wine-gallons, regard being only had to the proper gauge-point.

8. The two diameters of an ellipſis being given, to find the area in ale-gallons. Suppoſe the tranſverſe diameter 72 inches, and the conjugate 50: ſet 359.05, the ſquare of the gauge-point, on B, to one of the diameters (ſuppoſe 50) on A; then againſt the other diameter 72 on B, you will have the area on A, *viz.* 10.02 gallons, the content of this ellipſis at one inch deep. The like may be done for wine-gallons, if, inſtead of 359.05, you uſe 249.11, the ſquare of the gauge-point for wine-gallons.

9. To find the area of a triangular ſurface in ale-gallons. Suppoſe the baſe of the triangle 260 inches, and the perpendicular let fall from the oppoſite angle 110 inches: ſet 282 (marked A) upon B, to 130, half the baſe, on A; then againſt 110 on B is 50.7 gallons on A.

10. To find the content of an oblong in ale-gallons. Suppoſe one ſide 130 inches, and the other 180: ſet 282 on B, to 180 on A; then againſt 130 upon B is 82.97 ale-gallons, the area required.

11. To find the content of a regular polygon in ale-gallons, one of the ſides being given. Find the length of the perpendicular let fall from the centre to one of the ſides: this, multiplied by half the ſum of the ſides, gives the area. For an inſtance; ſuppoſe a pentagon, whoſe ſide is 1 inch, here the perpendicular will be found .837, by ſaying, as the ſine of half the angle at the centre, which, in this polygon, is 36°, is to half the given ſide .5, ſo is the ſine of the complement of 36°, *viz.* 54°, to the perpendicular aforeſaid. Whence the area of a pentagon, whoſe ſide is unity, will be found 1.72 inches, which, divided by 282, gives .0061, the ale-gallons in that polygon.

12. To find the content of a cylinder in ale-gallons. Suppoſe the diameter of the baſe of the cylinder 120 inches, the perpendicular height 36 inches: ſet therefore the gauge-point (A G) to the height 36 on C; then againſt 120, the diameter on D, is found 1443.6, the content in ale-gallons.

13. The bung and head-diameters of any caſk, together with its length, being given; to find its content in ale or wine-gallons. 1. Suppoſe the length of a caſk taken (as the middle fruſtum of a ſpheroid, which is the firſt caſe or variety) be 40 inches, its head-diameter 24 inches, and bung-diameter 32 inches: ſubtract the head-diameter from that of the bung, the difference is 8. Look, then, for 8 inches on the line of inches, on the firſt narrow face of the rule; and againſt it, on the line *ſpheroid*, ſtands 5.6 inches, which, added to the head-diameter 24, gives 29.6 inches for that caſk's mean diameter: ſet, therefore the gauge-point for ale (marked A G) on D, to 40 on C; and againſt 29.6 on D, is 97.45, the content of the caſk in ale-gallons. If the gauge-point for wine (marked W G) be uſed inſtead of that for ale, you will have the veſſel's content in wine-gallons.

2. If a caſk, of the ſame dimenſions as the former, be taken (as the middle fruſtum of a parabolic ſpindle, which is the *ſecond variety*), ſee what inches, and parts, on the line marked ſecond variety, ſtand againſt the difference of the bung and head-diameters, which, in this example, is 8; and you will find 5.1 inches, which, added to 24, the head-diameter, makes 29.1 inches, the mean diameter of the caſk: ſet, therefore, the rule, as before, and againſt 29.1 inches, you will have 94.12 ale-gallons for the content of the caſk.

3. If the caſk taken be the middle fruſtum of two parabolic conoids, which is the third variety; againſt 8 inches, the difference of the head and bung-diameters, on the line of inches, you will find 4.57 inches on the line called *third variety*; this, added as before to 24, gives 28.57 for the caſk's mean diameter; proceeding, as before, you will find the content 90.8 gallons.

4. If the caſk taken be the fruſtums of two cones, which is the *fourth variety*, againſt 8 inches on the line of inches,

you will find on the line marked F C, 4.1 inches to be added to 24 inches: the reſt, carried on as before, gives the content of the caſk 87.93 ale-gallons.

14. A caſk partly empty, lying with its axis parallel to the horizon; to find the quantity of liquor in it. Find its whole content as above, which ſuppoſe 97.455 gallons; and ſuppoſe the inches left dry, 8, and the bung-diameter 32: then, as the bung-diameter on C is to 100 on the line of ſegments L, ſo are the dry inches on C to a fourth number on the line of ſegments: and as 100 upon B is to the caſk's whole content on A, ſo is that fourth number to the liquor wanting to fill up the caſk, which, ſubtracted from the whole content of the caſk, gives the liquor remaining therein; *e. gr.* ſet 32, the bung-diameter on C, to 100 on the ſegment-line L; then againſt 8, the dry inches on C, ſtands 17.6 on the ſegment-line: ſet, therefore, 100 on B to the caſk's whole content on A; and againſt 17.6 on B, you have 16.5 gallons on A: ſubtracting, therefore, the ſaid gallons from 97.45, the veſſel's whole content, the liquor in the caſk will be 80.95 gallons.

15. A caſk ſtanding upright, or with its axis perpendicular to the horizon, to find the liquor therein. Suppoſe the length of the caſk 40 inches, and 10 of them dry; ſet 40 inches on the line C, to 100 on the ſegment-line S; and againſt 10, the dry inches on the line C, ſtands 24.2 on S, the ſegment-line. Set then 100 on B to 97.455, the caſk's whole content on A; and againſt 24.2 on B, you will have 23.5 gallons, which is what is wanting to fill up the caſk: this, therefore, ſubtracted from the whole content 97.455, gives 73.955 gallons, for the quantity of liquor remaining in the caſk.

16. To find the content of any right-angled parallelepiped (*e. gr.* a ciſtern, uting-fat, or the like) in malt buſhels. Suppoſe the length of the baſe 80 inches, the breadth 50, and depth 9 inches; ſet the breadth 50 on B, to the depth 9 on C; then againſt the length 80 on A, ſtand 16.8 buſhels on B, the number required.

SLIDING-*Rule, Coggeſhall's,* is principally uſed in meaſuring of the ſuperficies and ſolidity of timber, &c.

It conſiſts of two rulers, each a foot long, which are framed or put together various ways; ſometimes they are made to ſlide by one another, like glaziers' rules: ſometimes a groove is made in the ſide of a common two-foot joint-rule, and a thin ſliding-piece put in, and Coggeſhall's lines added on that ſide: but the moſt uſual and commodious way is, to have one of the rulers ſlide in a groove made along the middle of the other, as it is repreſented in *Plate* VII. *Surveying, fig.* 5.

On the ſliding ſide of the rule are four lines of numbers, three of which are double, that is, are lines to two radiuſes, and one, a ſingle broken line of numbers: the three firſt, marked A, B, C, are figured 1, 2, 3, &c. to 9; then 1, 2, 3, &c. to 10. Their conſtruction, uſe, &c. are the ſame as thoſe on Everard's ſliding rule. The ſingle line, called the *girt-line,* and noted D, whoſe radius is equal to the two radiuſes of any of the other lines, is broken, for the eaſier meaſuring of timber, and figured 4, 5, 6, 7, 8, 9, 10, 20, 30, &c. from 4 to 5. It is divided into 10 parts, and each tenth ſubdivided into two, and ſo on from 5 to 10, &c.

On the backſide of the rule are, 1. A line of inch-meaſure, from 1 to 12; each inch being divided and ſubdivided.

2. A line of foot-meaſure; conſiſting of one foot, divided into 100 equal parts, and figured 10, 26, 30, &c. The backſide of the ſliding-piece is divided into inches, halves, &c. and figured from 12 to 24; ſo that when ſlid out, there may be a meaſure of two feet.

SLIDING-*Rule, in meaſuring plain ſuperficies, uſe of Coggeſhall's.* 1. To meaſure a ſquare. Suppoſe, *e. gr.* the ſides be each five feet: ſet 1 on the line B, to 5 on the line A; then againſt 5 on the line B is 25 feet, the content of the ſquare on the line A.

2. To meaſure a long ſquare. Suppoſe the longeſt ſide 18 feet, and the ſhorteſt 10: ſet 1 on the line B, to 10 on the line A: then againſt 18 feet on the line B is 180 feet, the content on the line A.

3. To meaſure a rhombus. Suppoſe the ſide 12 feet, and the length of a perpendicular let fall from one of the obtuſe angles to the oppoſite ſide, 9 feet: ſet 1 on the line B, to 12, the length of the ſide, on the line A; then againſt 9, the length of the perpendicular on the line B, is 108 feet, the content.

4. To meaſure a triangle. Suppoſe the baſe 7 feet, and the length of the perpendicular let fall from the oppoſite angle to the baſe 4 feet: ſet 1 on the line B, to 7 on the line A: then againſt half the perpendicular, which is 2 on the line B, is 14 on the line A, for the content of the triangle.

5. To find the content of a circle, its diameter being given. Suppoſe the diameter 3.5 feet: ſet 11 on the girt-line D, to 95 on the line C; then againſt 3.5 feet on D, is 9.6 on C, which is the content of the circle in feet.

6. To find the content of an oval or ellipſis. Suppoſe the longeſt diameter 9 feet, and the ſhorteſt 4. Find a mean proportional between the two, by ſetting the greater 9 on the girt-line, to 9 on the line C; then, againſt the leſs number 4, on the line C, is 6, the mean proportional ſought. This done, find the content of a circle, whoſe diameter is 6 feet; this, when found by the laſt article, will be equal to the content of the ellipſis ſought.

SLIDING-*Rule, in meaſuring timber, uſe of Coggeſhall's.* 1. To meaſure timber the uſual way. Take the length in feet, half feet, and, if required, quarters; then meaſure half-way back again; there girt the tree with a ſmall cord or line; double this line twice, very evenly; and meaſure this fourth part of the girt or perimeter, in inches, halves, and quarters. The dimenſions thus taken, the timber is to be meaſured as if ſquare, and the fourth of the girt taken for the ſide of the ſquare, thus; ſet 12 on the girt-line D, to the length in feet on the line C; then againſt the ſide of the ſquare, on the girt-line D, taken in inches, you have, on the line C, the content of the tree in feet.

For an inſtance: ſuppoſe the girt of a tree, in the middle, be 60 inches, and the length 30 feet, to find the content: ſet 12 on the girt-line D, to 30 feet on the line C; then againſt 15, one-fourth of 60, on the girt-line D, is 46.8 feet, the content on the line C. If the length ſhould be 9 inches, and the quarter of the girt 35 inches, here, as the length is leſs than a foot, meaſure it on the line of foot-meaſure, and ſee what decimal part of a foot it makes, which you will find .75: ſet 12, therefore, on the girt-line, to 75 on the firſt radius of the line C, and againſt 35 on the girt-line is 6.4 feet on C, for the content.

2. To meaſure round timber the true way. The former method, though that generally in uſe, is not quite juſt. To meaſure timber accurately, inſtead of the point 12 on the girt-line, uſe another, *viz.* 10.635; at which there ſhould be placed a centre-pin. This 10.635 is the ſide of a ſquare equal to a circle, whoſe diameter is 12 inches. For an inſtance: ſuppoſe the length 15 feet, and $\frac{1}{4}$th of the girt 42 inches: ſet the point 10.635 to 15, the length;

then againſt 42 on the girt-line is 233 feet for the content ſought; whereas, by the common way, there ariſe only 184 feet. In effect, the common meaſure is only to the true meaſure, as 11 to 14. See TIMBER.

3. To meaſure a cube. Suppoſe the ſides to be 6 feet each: ſet 12 on the girt-line D, to 6 on C; then againſt 72 inches (the inches in 6 feet) on the girt-line are 216 feet on C, which give the content required.

4. To meaſure unequally ſquared timber; that is, where the breadth and depth are not equal. Meaſure the length of the piece, and the breadth and depth (at the end) in inches; then find a mean proportional between the breadth and depth of the piece. This mean proportional is the ſide of a ſquare equal to the end of the piece: which found, the piece may be meaſured as ſquare timber.

For an inſtance: let the length of the piece of timber be 13 feet, the breadth 23 inches, and the depth 13 inches: ſet 23 on the girt-line D, to 23 on C; then againſt 13 on C is 17.35 on the girt-line D for the mean proportional. Again, ſetting 12 on the girt-line D to 13 feet, the length on the line C, againſt 17.35, on the girt-line is 27 feet, the content.

5. To meaſure taper timber. The length being meaſured in feet, note one-third of it; which is found thus: ſet 3 on the line A, to the length on the line B; then againſt 1 on A is the third part on B: then if the ſolid be round, meaſure the diameter at each end in inches, and ſubtract the leſs diameter from the greater; add half the difference to the leſs diameter; the ſum is the diameter in the middle of the piece. Then ſet 13.54 on the girt-line D to the length on the line C, and againſt the diameter in the middle, on the girt-line, is a fourth number on the line C. Again, ſet 13.54 on the girt-line to the third part of the length on the line C; then againſt half the difference on the girt-line, is another fourth number on the line C: theſe two fourth numbers, added together, give the content. For an inſtance: let the length be 27 feet (one-third of which is 9), the greater diameter 22 inches, and the leſs 18; the ſum of the two will be 40, their difference 4, and half the difference 2, which, added to the leſs diameter, gives 20 inches for the diameter in the middle of the piece. Now, ſet 13.54 on the girt-line, to 27 on the line C, and againſt 20 on D is 58.9 feet. Again, ſet 13.54 on the girt-line to 9 on the line C; and againſt 2 on the girt-line (repreſented by 20) is .196 parts; therefore, by adding 58.9 feet to .196 feet, the ſum is 59.096 feet, the content.

If the timber be ſquare, and has the ſame dimenſions; that is, the length 27 feet, the ſide of the greater end 22 inches, and that of the leſſer 18 inches; to find the content: ſet 12 on the girt-line to 27, the length on the line C; and againſt 20 inches, the ſide of the mean ſquare on the girt-line, is 75.4 feet. Again, ſet 12 on the girt-line to 9 feet, one-third of the length, on the line C; and againſt 2 inches, half the difference of the ſides of the ſquares of the ends on the girt-line, is .25 parts of a foot: both together make 75.65 feet, the content of the ſolid.

The girt or circumference of a tree, or round piece of timber, given; to find the ſide of the ſquare within, or the number of inches of a ſide when the round timber is ſquared. Set 10 on A to 9 on B; then againſt the girt on A are the inches for the ſide of the ſquare on the line B. See DENDROMETER.

Dr. Roget has lately communicated to the Royal Society the "Deſcription of a new Inſtrument for performing the Involution and Evolution of Numbers," by which he has very much improved the conſtruction, and extended the application of the "ſliding-rule."

In his ingenious paper on this ſubject, he has ſtated and elucidated the general principles on which inſtruments of this kind are conſtructed, and the ordinary purpoſes to which they are applicable. It is well known, that the Gunter's line and common ſliding-rule are derived from the properties of logarithms, and that their primary uſe conſiſts in facilitating the *multiplication* and *diviſion* of numbers. (See GUNTER's *Line* and GUNTER's *Scale*.) Our author's inſtrument is founded on a particular mode of employing logarithms, and is deſigned for immediate application to the *involution* and *evolution* of numbers. The common ſliding-rule, it is obvious, ſerves for comparing the intervals between the numbers on Gunter's ſcale; and for this purpoſe it conſiſts of a ſcale, called the ſlider, exactly of the ſame length with the former, and bearing the ſame diviſions, which, by being moveable along the ſide of the other, allows of the application of any part of the one to any part of the other. If the two ſcales originally coincide, and the ſliding ſcale is the undermoſt, then, by advancing the ſlider through any given diſtance, each of its diviſions will be brought under thoſe of the fixed ſcale, which before were reſpectively ſituated farther forwards by an interval equal to that given diſtance. Every number in the upper ſcale will therefore have to the number ſtanding under it on the ſlider the ſame conſtant ratio; a ratio indicated by the number under which the unity, or commencement of the ſcale of the ſlider has been placed. The former numbers will therefore be the multiples of the latter by this conſtant number. Thus, by adjuſting the ſlider ſo that its unity ſhall ſtand under any given multiplier or diviſor, the upper line will exhibit the ſeries of the products of all the ſubjacent numbers by the given multiplier; and converſely, the ſlider will exhibit the ſeries of the quotients reſulting from the diviſion of the numbers immediately above them by the given diviſor. In order to facilitate the general uſe of the ſliding-rule, Dr. Roget has pointed out the following propoſition, as leading directly to the ſolution of every caſe to which the inſtrument can be applied. "In every poſition of the ſlider, all the fractions formed by taking the numbers on the upper line as numerators, and thoſe immediately under them as denominators, are equal. Thus, every correſponding numerator and denominator, having to each other the ſame ratio, may be conſidered as two terms of a proportion. Any two of theſe equivalent fractions will therefore furniſh the four terms of a proportion; of which any unknown term may be ſupplied when the others are given, by moving the ſlider till the numbers compoſing the terms of the given fraction are brought to coincide on the two lines. The required term will then be found occupying its proper place oppoſite to the other given term. Thus, from the proportion A : B :: C : D, we may derive $\frac{A}{B} = \frac{C}{D}$; and adjuſting the ſlider ſo that B ſhall ſtand under A, D will be found under C, when C is given; or C will be found over D, when D is given. A ſimilar proceſs would have furniſhed A or B, when one of them, together with C and D, were given. Since the products of each numerator by the denominator of the other fraction are equal (that is, $AD = BC$); when one of the terms is unity, the queſtion becomes one of ſimple multiplication or diviſion. The product of A and B, which we may call P, will be found as before, by placing the ſlider ſo as to expreſs the fractions $\frac{A}{1} = \frac{P}{B}$. The quotient of A divided by B, which we may call Q, will in like manner be found by forming the fractions $\frac{A}{B} = \frac{Q}{1}$; that is, in the former caſe, the product P will ſtand over B, when the 1 on the ſlider is brought under A; and in the latter caſe, the quotient Q will ſtand over the 1 of the ſlider when B is brought under A."

The ſliding-rule has been variouſly modified, ſo as to ſerve for the calculation of exchanges, the meaſurement of plane and ſolid bodies, and the computations of trigonometry; and lately by Dr. Wollaſton, in his ſynoptic ſcale of chemical equivalents; but notwithſtanding theſe modifications, its uſe is neceſſarily limited to operations that are performed by the ſimple addition or ſubtraction of logarithms, and to the correſponding arithmetical operations above mentioned. It is not directly adapted to perform the involution or evolution of numbers, to which the multiplication and diviſion of logarithms correſpond. (See LOGARITHM.) Neverthele ſs, queſtions that involve geometrical progreſſions, or exponential quantities, and the computation of the terms of a ſeries in obtaining approximate ſolutions, not unfrequently occur. The common ſliding-rule affords no direct method of determining even the ſimple power or root of any given number; but when the exponent of the required power or root is not an integral, but a fractional number, it is ſtill more inadequate to the ſolution of the queſtion. Indeed, the ſquares and ſquare roots are often pointed out on the common rules by means of a ſupplementary line graduated ſo that each of its diviſions is double in length to thoſe of the other two lines. A line of cubes, or cube-roots, or of any other given power, might, in like manner, be ſubjoined. But the uſes of ſuch additional lines are reſtricted to caſes where a particular power is concerned; but they afford no aſſiſtance in the caſe of any other power or root, which is not immediately related to the power.

Dr. Roget adopts a new mode of graduation, exhibiting on ſimple inſpection all the powers and roots of any given number to any given exponent, with the ſame facility, and in the ſame way, that products, quotients, and proportionals are exhibited by the common ſliding-rule. Accordingly it is a meaſure of powers, juſt as the ſcale of Gunter is a meaſure of ratios. The principle of its conſtruction will be beſt illuſtrated by an example. If it were required to raiſe the number 2.123 to the fifth power; with the uſe of logarithms we ſhould multiply the log. of 2.123 (or 0.32695) by 5; the product (1.63475) would be found by the tables to correſpond to 43.127, the fifth power of 2.123. If the exponent, inſtead of being a whole number 5, were fractional, as 4.3719, the operation may be abridged by the aid of logarithms: thus, add the log. of 0.32695 or 9.5144813, to that of 4.3719 or 0.6406702, and the ſum, or 0.1551525, is a logarithm anſwering to the number 1.4294, the product required, *viz.* 26.878, or $\overline{2.123}|^{4.3719}$.

In this example, the firſt of the numbers added together is the logometric logarithm (that is, the logarithm of the logarithm) of the given root; the ſecond is the ſimple logarithm of the exponent, and the ſum of theſe is the logometric logarithm of the power. If a table were conſtructed having three ſets of columns, the firſt containing the natural ſeries of numbers, the ſecond their correſponding logarithms, and the third the logarithms of thoſe logarithms, we ſhould be able to raiſe any given number to any given power, by the ſimple addition of the numbers in the ſecond and third columns; as common multiplications are performed by the addition of common logarithms. Hence it is evident, that a line might be graduated ſo that its diviſions ſhould correſpond to the numbers in the third column, or repreſent the logometric logarithms of the numbers marked upon them; and if this line were applied ſo as to ſlide againſt another line logometrically divided, we might be able by it to perform the operation that has been deſcribed; and we ſhould thus have, by inſpection, the powers correſponding to any given root and exponent.

The inſtrument propoſed would therefore, in its ſimpleſt form, conſiſt of two graduated ſcales applied to each other.

In *Plate* VII. *Surveying, fig.* 6. a portion of theſe ſcales is repreſented. The lower rule A A, called the ſlider, is the common Gunter's double line of numbers, or a line logometrically divided; the diviſions of the firſt half being from 1 to 10, and repeated on the ſecond half in the ſame order. The upper, or fixed rule B B, is ſo graduated, that each of its other diviſions is ſet againſt its reſpective logarithm on the ſlider; and, conſequently, all the numbers on the ſlider will be ſituated immediately under thoſe numbers in the upper rule, of which they are the logarithms. Thus, 2 on the rule will be over 0.30103 of the ſlider; 3 over 0.47712; 2 on the ſlider will ſtand under 100 on the rule; 3 under 1000, and ſo on.

As the ſeries of ordinary logarithms expreſs the exponents of 10, of which the correſponding numbers are ſo many ſucceſſive powers, in this poſition of the inſtrument it is evident, that the upper line will exhibit the ſeries of the powers of 10, correſponding to all the exponents marked on the ſlider. *E. gr.* The 2d power of 10 is 100; the 3d, 1000, &c.; the 0.5th (or the ſquare root) is 3.163; the 0.25th (or 4th root) is 1.778; the 0.2th (or the 5th root) is 1.585, &c.

In every other poſition of the ſlider, the upper rule will exhibit, in like manner, the ſeries of powers of that number, under which the unit of the ſlider has been placed, while the oppoſite numbers on the ſlider are the exponents of thoſe powers. Thus, if (*Plate* VII. *fig.* 7.) the unit of the ſlider be placed under the diviſion 3 of the upper rule (at R), the ſquare of 3, or 9, will be found over the 2 of the ſlider; its cube, 27, over the 3; its 4th power, 81, over the 4, &c. Hence, in order to find a given power of any number, the unit of the ſlider muſt be ſet underneath that number in the upper rule; and the number ſought will then be found above that number in the ſlider, which expreſſes the magnitude of the required power. The uſe of the inſtrument will be obvious in performing the contrary operation of finding the roots. In this caſe the root might be conſidered as a fractional power; but as this would require a reduction into decimals, the eaſieſt mode will be to place the number expreſſing the degree of the required root under the given number, and the root itſelf will then be found over the unit, or beginning of the ſcale, in the ſlider. For fractional powers, the denominator of the exponent muſt be placed under the root, and its numerator will then point out the power. By the ſame mode we may diſcover the exponent of any given power to any given root; ſince, whatever be the root over the unit of the ſlider, the whole ſeries of the powers of that root, with their correſponding exponents, are rendered apparent. This circumſtance may be conſidered as an additional recommendation to the employment of this inſtrument; for it affords to thoſe leſs verſed in the contemplation of numerical relations, an ocular illuſtration of the theory of involution. It preſents, at one view, the whole ſeries of powers ariſing from the ſucceſſive multiplication of all poſſible numbers, whether entire or fractional; and exhibits this ſeries in its whole continuity, when the exponents are fractional, and even incommenſurate with the root itſelf. The production of the upper line in one direction, conveys a more accurate notion of the progreſſive and rapid increaſe of thoſe powers, than can be acquired by mere abſtract reflection; and its continuation on the other ſide ſhews the ſlow approximation to unity which takes place in the ſucceſſive extractions of higher and higher roots. Among the variety of forms of conſtruction of which inſtruments that operate on the principle now explained are capable, Dr. Roget conceives the following to be, upon the whole, the moſt convenient for practical purpoſes. Its repreſentation, on a reduced ſcale, appears in *Plate* VII. *fig.* 8. With a view of preſerving a ſufficient extent of ſcale, the line of roots and powers is divided into two parts; one being placed above and the other below, and between them a ſlider with a double ſcale of exponents. The ſlider of the common ſliding-rule is graduated in a way that is exceedingly well ſuited to this purpoſe, having diviſions on each edge, and carrying two ſets of numbers from 1 to 10. Adapting a blank ruler to one of theſe ſliders, which muſt be fixed in a proper poſition, Dr. Roget marks off, on the upper line, the ſeries of numbers againſt their reſpective logarithms on the ſliders; placing 10 over the middle unit of the ſlider, 100 over the 2, 1000 over the 3, and ſo on, proceeding towards the right, from 10 to 10000000000, the 10th power of 10; an extent which is more than ſufficient for all uſeful purpoſes. The ſpace to the left is alſo graduated on the ſame principle, from 10 to 1.259, which is the 10th root of 10, or $\overline{10}|^{0.1}$. The upper portion of the rule being thus filled, Dr. R. places the continuation of the ſame line on the lower portion, beginning on the right hand, and proceeding in a deſcending ſeries of fractional powers of 10, correſponding with the exponents on the intermediate ſlider, which, when applied to this portion, are to be taken as only $\frac{1}{100}$th of their value when applied to the upper portion. While 1.259 therefore is marked on the right, 1.0233 ($= \overline{10}|^{0.01}$) will occupy the middle, and 1.002305 ($= \overline{10}|^{0.001}$) the left end of the lower line. The graduation, it is plain, might be thus continued indefinitely in both directions. But for all practical purpoſes, the limits thus obtained will be found amply ſufficient. In proportion as numbers in a deſcending ſeries approach very near to unity, their logarithms bear more and more exactly a conſtant ratio to the exceſs of thoſe numbers above unity, *viz.* the ratio expreſſed by the modulus of the ſyſtem, or 1 to .4342944819. As we deſcend in the ſcale, therefore, the decimal part of the exponents becoming ſmaller and ſmaller, the correſponding logarithms will approximate ſo nearly to the multiple of that decimal part by this modulus, that no ſenſible error will reſult from aſſuming them to be the ſame. Thus the log. of 1.05 is .021189; that of 1.005 is .0021661; and that of 1.0005 is .00021709, which differs from the product of the modulus by .0005 (or .00021715) by a quantity affecting only the 4th ſignificant figure. The roots 1.0005, 1.00005, 1.000005, &c. may, therefore, without ſenſible error, be conſidered as coinciding with the diviſion 217 on the ſlider. Hence, the diviſions to the left of the lower portion of the rule may be taken as ſufficiently accurate repreſentations of the diviſions which would occur in the ſucceeding portions of the line, if it were prolonged indefinitely in that direction.

This inſtrument may, from the principle of its conſtruction, be applied to the ſolution of various problems in which geometrical progreſſions are concerned. *E. g.* As the ſucceſſive amounts of a ſum placed at compound intereſt compoſe a geometrical progreſſion, all queſtions of compound intereſt are reſolvable by this inſtrument. The rate of intereſt, or the *per centage per annum*, being added to 1, gives the amount of 1*l.* at the end of one year. Thus, at 5 *per cent.* the amount is 1.05, at 3 *per cent.* 1.03, &c. In either caſe this number is to be regarded as the firſt term, or root of the ſeries. Setting the unit of the ſlider againſt this number on the rule, we ſhall find the amount of 1*l.* at the end of 5½ years oppoſite to the number 5.5 on the ſlider, and the ſame of any other interval of time. If it be required to aſcertain in what time a ſum placed at compound intereſt at 3 *per cent.* will be doubled; placing the unit over 1.03, the number 2 on the rule will indicate 23.45 on the ſlider, as the number of years required for doubling the ſum at that rate of compound intereſt. The interpolation of a given number of mean proportionals between two given numbers, is ſometimes required for the ſolution of a problem; and it is eaſily effected by the rule above deſcribed. Thus, in dividing the muſical octave into 12 equal ſemitones, the following ſeries of numbers muſt be calculated, *viz.* $2^{\frac{1}{12}}$, $2^{\frac{2}{12}}$, $2^{\frac{3}{12}}$, $2^{\frac{4}{12}}$, $2^{\frac{5}{12}}$, $2^{\frac{6}{12}}$, $2^{\frac{7}{12}}$, $2^{\frac{8}{12}}$, $2^{\frac{9}{12}}$, $2^{\frac{10}{12}}$, $2^{\frac{11}{12}}$: this may readily be done in one poſition of the ſlider; for when the 12 marked on it is placed under 2 on the rule, the 1 of the ſlider will point to $1.0595 = 2^{\frac{1}{12}}$, the 2 of the ſlider will indicate $1.1225 = 2^{\frac{2}{12}}$, the 3, $1.1892 = 2^{\frac{3}{12}}$, &c.

A variety of queſtions relating to the general theory of logarithms may be illuſtrated by this inſtrument. The aſſumption of the number 10, as the baſis of our ſyſtem of logarithms, is arbitrary, and choſen merely for greater convenience in computation. The hyperbolic ſyſtem, whoſe baſis is the number 2.302585093, &c. has its peculiar advantages, eſpecially in the higher branches of analyſis. The inſtrument may be made to exhibit at one view the ſeries of any particular ſyſtem of logarithms, that is, of a ſyſtem with any given baſis, or any given modulus, by merely ſetting the unity of the ſlider againſt the given baſis on the rule, or the given modulus on the ſlider againſt the number 2.7182818, &c. on the rule. The diviſions on the ſlider will then denote the logarithms of the numbers oppoſed to them on the rule.

Let it be required to determine the particular ſyſtem of logarithms, in which the modulus ſhall be equal to the baſis. Take out the ſlider, and introduce it in an inverted poſition, ſo that the numbers on it ſhall increaſe from right to left; and place the numbers .4343, &c. (the modulus of the common ſyſtem) under 10 (its correſponding baſis) on the rule, as repreſented in *Plate* VII. *fig.* 9. We ſhall find that, in this poſition, all the other numbers on the ſlider will be the moduli correſponding to the reſpective baſes of each different ſyſtem on the rule. Thus, the 1 on the ſlider, or the modulus of the hyperbolic ſyſtem, is oppoſite to 2.718, the baſis of that ſyſtem. On the other hand, the diviſion 2 on the rule is oppoſite to 1.4427, which is the modulus of the ſyſtem having for its baſis the number 2. Carrying the eye ſtill more to the left, and obſerving the point where ſimilar diviſions appear, both on the rule and the ſlider, we ſhall find it to be at the number 1.76315, which therefore expreſſes the modulus and the baſis in that particular ſyſtem in which they are both equal. The reaſon of the above proceſs will readily appear, when it is conſidered, that the modulus of every ſyſtem is the reciprocal of the hyperbolic logarithm of its baſis.

This inverted condition of the ſlider will alſo afford an eaſy method of ſolving exponential equations, for which there exiſts no direct analytical method. *E. g.* Let the root of the equation $x^x = 100$ be required. Set the unit of the inverted ſlider under 100 on the rule, and obſerve, as before, the point where ſimilar diviſions coincide: this will be at

3.6,

3.6, which is a near approximation to the required root; and accordingly, $\overline{3.6}|^{3.6} = 100$.

Our author's inſtrument admits of being applied in various forms to the ſeveral purpoſes above recited, as well as to others which he has enumerated: but the following deſerves particular mention, on account of the peculiarities that attend them. If to the upper ſcale, which we may ſuppoſe to be fixed, and to be graduated logometrically, conſtituting the line of exponents, a ſlider be adjuſted, graduated on both edges, according to the logometric logarithms; and the line below, which, like the upper one, is ſuppoſed to be fixed, be graduated in the ſame manner as the ſlider, the inſtrument will poſſeſs the following property. When the diviſion 10 on the ſlider is ſet againſt any particular number, or exponent, in the upper line, all the numbers on the lower line will be the powers, to the ſame degree, of the numbers oppoſite to them on the ſlider; the degree of the power being marked by the exponent on the upper line, which is above the 10 on the ſlider. The lower line will, therefore, exhibit the whole ſeries of ſimilar powers belonging to all poſſible roots; and converſely, the ſlider will exhibit all the roots of the ſame dimenſions, with regard to all poſſible numbers. Thus, if the 10 on the ſlider be under 3 in the line of exponents, it will itſelf be above 1000 (which is its cube) in the lower line; all the other numbers in that line will be the cubes of their oppoſites on the ſlider; and, converſely, the former will every where be the cube-roots of the latter. This will ſufficiently appear, when it is recollected that the addition or ſubtraction of logometric logarithms, anſwers to the multiplication or diviſion of ſimple logarithms, and therefore to the involution and evolution of numbers. The rule in this form of it, therefore, bears a cloſer analogy to the common ſliding-rule; ſince in every poſition it exhibits the ſeries of ſimilar powers and roots, exactly in the ſame way as the latter exhibits the ſeries of ſimilar products and quotients.

Dr. Roget has alſo contrived to give another form to the inſtrument, by throwing the whole ſcale, like Gunter's line, into a circular form: and of this form he has given a drawing. The circle on the outſide being logometrically divided from 1 to 10 round the circumference, will conſtitute the line of exponents. The line of powers, being diſpoſed in a ſpiral, will occupy the interior ſpace, which may be made to revolve within the former, and ſhould be provided with one or more threads, extending from the centre to the circumference, and ſerving as radii to mark the poſition of all the parts of the ſpiral line with regard to the diviſions of the outer circle. One of theſe threads may be fixed at the unit or beginning of the ſcale, and will ſerve to mark the poſition for the root of any required power. The ſpiral itſelf muſt be graduated exactly as the upper line in the firſt deſcribed rule; that is, the ſituation of the diviſion 10 muſt be firſt determined upon, and then brought under the unit in the circle of exponents; that is, under the fixed thread. Every other diviſion muſt then be marked with reference to the place of its logarithm on the circle, or muſt be made to occupy the ſame angular diſtance from the thread. This graduation will be moſt conveniently made by means of the moveable leg of a ſector revolving on the centre of the circle. The compariſon of the diviſions of the ſpiral with thoſe of the circle may be made, either with this moveable ſector, or with the threads already mentioned. The numbers on the ſpiral will increaſe as they recede from the centre, and each turn will carry on the powers to an exponent ten times higher than the preceding; and the converſe will obtain with regard to the deſcending portion. Thus, immediately in a line with the 10, on the ſuperior branch of the ſpiral, is found the number 10000000000, or 10^{10}; below it, on the inferior branches, we find ſucceſſively $1.258926 = 10^{0.1}$, $1.023293 = \overline{10}|^{0.01}$, $1.00230524 = \overline{10}|^{.001}$, $1.000230285 = \overline{10}|^{.0001}$, $1.0000230261 = \overline{10}|^{.00001}$, &c. of which the decimal figures approach nearer and nearer to 2.302585093, &c. the reciprocal of the modulus of the logarithmic ſyſtem. Our ingenious author has further ſhewn how to exhibit in one view the whole ſeries of roots, powers, and exponents, in all their poſſible relations, by a ſuitable diſpoſition of lines. For further particulars we refer to the Phil. Tranſ. for 1815, part 1. p. 9, &c. For an account of Mr. W. Nicholſon's improvements of the Gunter's ſcale, &c. ſee the Phil. Tranſ. for 1787, vol. lxxvii. part 2. See GUNTER's *Line* and *Scale*.

SLIDING-*Keels*, in *Ship-Building*, an invention of the ingenious captain Schank, of the royal navy, to prevent veſſels from driving to leeward. They were compoſed of plank of various widths, erected vertically by a winch, ſo as to ſlide up and down in a trunk, and through the keel. Many veſſels were built with no leſs than three of theſe keels; but it has not ſeemed to have anſwered.

SLIDING-*Planks*, are the flat forms upon which the bilge-ways ſlide in launching the ſhip.

SLIDING-GUNTER-SAIL, in *Sail-Making*, a triangular ſail, uſed in boats, bent at its foremoſt leech to loops or grommets that ſlide on the lower maſt: the peek or head is attached to a ſmall top-maſt, that ſlides up in the direction of the lower maſt, through two hoops fixed at its head, about three feet aſunder. When the top-maſt is lowered, the ſail furls up cloſe to the lower maſt.

SLIEBH, or SLIABH, the Iriſh name for a range of mountains, or a ſingle one, covered with heath. O'Brien ſays it ſignifies heath-land, whether mountain or plain. It is prefixed to the names of many Iriſh hills.

SLIEBH-AN-ERIN, in *Geography*, a range of mountains in the county of Leitrim, Ireland, extending in a N.E. direction from Lough Allen.

SLIEBH-EN-EWR, called alſo *Dartry* mountains, a cluſter of hills, covering almoſt the whole of the northern barony of the county of Leitrim, Ireland. Of theſe and the preceding it is obſerved by Dr. Beaufort, that they are far from unprofitable; for producing abundance of coarſe graſs, they annually pour forth immenſe droves of young cattle.

SLIEVE-BAUGHT MOUNTAINS, a chain of mountains on the confines of the counties of Monaghan and Tyrone, and extending into both. They form an uninterrupted ridge of high land, the higheſt part of which is called Cairn-more. They have, in general, neither a fruitful ſoil, nor any natural beauties to recommend them, being an uninteresting waſte, and almoſt always wet and moory. There are parts, however, which have beds of the richeſt limeſtone, and abundance of marle, particularly on the eaſtern ſide of Cairn-more. This mountain is famous for its millſtone quarry: thoſe moſt valued conſiſt of a red and very hard grit or ſand-ſtone, the grain of which is cloſe: there is alſo a ſoft whitiſh ſand-ſtone, more eaſily procured, but which ſoon waſtes away. Potters' clay found in the neighbourhood is carried to the pottery at Dundalk. Stat. Ac. of Monaghan.

SLIEBH-BAUGHTA MOUNTAINS, an extenſive range of rather low hills, which cover the ſouthern part of the county of Galway, and the adjoining part of Clare, in Ireland.

SLIEBH-BLOOM, or SLIE-BLOOM, a mountain in Ireland, or rather a chain of mountains, of conſiderable extent, dividing the King's and Queen's counties, and extending into the county of Tipperary. It is about 25 miles in length, and, in ſome parts, 10 miles broad, at the baſe. It is very unequal in height. Some few ridges are of conſiderable altitude, eſpecially thoſe which divide Eli O Carrol from Oſſory. One of theſe is called *Ard-Erin*, *i. e.* the higheſt part of Ireland. This, however, is very doubtful, as it is probable that no accurate compariſon on the ſubject has been ever made. Slie-bloom affords, in general, good paſturage, and in ſome parts, like many other Iriſh mountains, is green to the ſummit; but in other parts it is rocky, wild, and inacceſſible, inſomuch that wolves are ſaid to have found harbour in its caverns later than in any other part of the kingdom, even within the laſt century.

Some of the declivities of this mountain yield good corn, and are highly improved by plantations, and gentlemen's ſeats which command very extenſive and pictureſque views. It is remarkable for the number of fine rivers that ſpring from it. Three of theſe form an intereſting ſubject to poets as well as geographers. "Near Oſſory," ſays Camden, "are thoſe huge copling mountains named *Sliew-blamy*, which Giraldus calls *Bladinæ Montes*, of a vaſt height, out of the bowels whereof ſpring three rivers, the Suire, the Nore, and the Barrow. Theſe deſcend in three ſeveral channels, but join in one before they fall into the ſea, which made the ancients call them the Three Siſters."

It may be obſerved, that the moderns likewiſe call them ſiſters, although Spenſer repreſents them as brothers, the ſons of the giant Blœmius and the nymph Rheuſa, born in the mountain Slew-bloome; and the poet thus deſcribes their courſes and final confluence.

"Theſe three fair ſons, which being thenceforth powr'd,
In three great rivers ran, and many countreis ſcowr'd.
The firſt, the gentle Shure, that, making way
By ſweet Clonmel, adornes rich Waterford;
The next, the ſtubborn Newre, whoſe waters gray,
By faire Kilkenny and Roſſeponte boord;
The third, the goodly Barrew, which doth hoord
Great heaps of ſalmons in his deepe boſome:
All which, long ſundred, doe at laſt accord
To ione in one ere to the ſea they come;
So, flowing all from one, all one at laſt become."
Fairie Queen, book iv. canto xi.

For a more particular account of the three ſiſters of Slie-bloom, ſee BARROW, NORE, and SUIRE; and for a deſcription of the ſoil, quarries, &c. of this mountain, ſee KING'*s* and QUEEN'*s Counties*.

SLIEBH-BONN MOUNTAINS, a range of mountains in the county of Roſcommon, Ireland, extending nearly parallel to the Shannon, at a few miles diſtance, from Ruſkybridge to Laneſborough.

SLIEBH-BUY MOUNTAINS, a mountainous tract in the county of Wexford, Ireland, near the borders of Wicklow.

SLIEBH-CROOB MOUNTAINS, in the county of Down, Ireland, north of the Mourne mountains, and lying between Ballynahinch and Caſtlewellan.

SLIEBH-DHAM, a mountainous range in the weſtern part of the county of Sligo, Ireland, being part of the ridge to which Arrowſmith has given the name of Knock-na-ree.

SLIEBH-DONARD, one of the Mourne mountains, in the county of Down, Ireland, ſaid to be the higheſt of them, and to be 2800 feet in height. See MOURNE.

SLIEBH-GALLAN, a cluſter of hills in the ſouth of the county of Londonderry, Ireland; about 1250 feet above the level of the ſea.

SLIEBH-GULLIEN, in the ſouth-eaſt of the county of Armagh, Ireland, which is thought to be nearly as high as Sliebh-Donard; and which, like it, conſiſts of granite. It has a cairn on the ſummit.

SLIEBH-LEAGUE MOUNTAINS, a cluſter which occupies the peninſula weſt of Killybegs, in the county of Donegal, Ireland; called by Arrowſmith *Sleave-long*.

SLIEBH-LOGHER MOUNTAINS, in the county of Kerry, Ireland, on the borders of the county of Cork. Spenſer has repreſented this range as the ſource of the river Allow:

"Strong Allo tumbling from Sliebh-Logher ſteep:"

but in this he departs from geographical accuracy, as the Allow takes its riſe in the Limerick mountains, and the Blackwater paſſes under Sliebh-Logher, from which it receives a large ſupply of water. See BLACKWATER.

SLIEBH-MISH, a range of hills ſouth of Tralee, in the county of Kerry, Ireland.

SLIEBH-MORE, a mountain in Achil iſland, county of Mayo, Ireland.

SLIEBH-NA-COILTRA MOUNTAINS, a range in the county of Wexford, Ireland, ſouth of the town of New Roſs.

SLIEBH-NA-MAN, a high mountain of the county of Tipperary, Ireland, not far from the Nine-mile houſe, on the road from Clonmel to Kilkenny.

SLIEBH-NA-MUCK, a range of hills N. of the Galtees, in the county of Tipperary, Ireland, extending eaſt and weſt, and lying ſouthward of the town of Tipperary.

SLIEBH-RUSSEL, a mountain of the county of Cavan, Ireland, near Swanlinbar.

SLIEBH-SNAGHT, a mountain of the county of Donegal, Ireland, in the peninſula of Iniſhowen.

SLIGO, a county of Ireland, in the province of Connaught, bounded on the E. by the county of Leitrim, on the S. by Roſcommon, on the S.W. and W. by Mayo, and on the N. by the bay of Donegal. Its greateſt length, from Bunduff in the N. to the Curlew mountains in the S. is 31 Iriſh (39½ Engliſh) miles, and the greateſt breadth 29 Iriſh (37 Engliſh) miles. It contains 247,150 acres, or 386 ſquare miles, Iriſh meaſure, equal to 397,060 acres, or 620 ſquare miles, Engliſh. The number of houſes was 11,509, ſuppoſed to contain 60,000 inhabitants; but the documents on which this is ſtated were very imperfect, and the increaſe muſt have been inconſiderable. There are 39 pariſhes, of which 16 only had churches when Dr. Beaufort publiſhed his valuable work; they lie in the biſhoprics of Elphin, Achonry, Killalla, and Ardagh. This county and the town of Sligo are repreſented in parliament by three members.

Sligo contains very good land, intermixed with large tracts of coarſe and unprofitable ground. In the northern diſtrict, lying between the county of Leitrim and the ſea, are the mountains of Benbulb and Samore. A chain of rough hills extends from Lough Gilly to the bounds of Roſcommon and Leitrim. The barony of Tyreragh, though level along the coaſt, is interſected by large bogs; and the ſouthern part of it is bounded by the Ox mountain, Sliebh-Dham, and a great range of deſolate hills, that extend acroſs the middle of the country; whilſt the Curlews and other mountains cover much of the ſouthern part of it. Among theſe hills there are many large lakes, and abundance of rivers. The Moy, which riſes in the mountain of Knockna-ree, flows firſt to the ſouthward, and after a winding courſe, takes a northerly direction to the bay of Killalla. It receives in its courſe the ſuperfluous waters of Lough Conn, and forms, for ſome miles, the weſtern boundary of the county. Lough Arrow is about eight miles long, full of iſlands, and of a very irregular form: a river of the ſame name proceeds from it, and running northward to Ballyſadere, ruſhes at once into the ſea in a ſtupendous cataract. Lough Garra, on the borders of Roſcommon, in the moſt ſouthern part of the county, communicates with Lough Key by the river Boyle, which joins the Shannon. Lough Gilly exhibits that variety of charming proſpects which bold hills, wooded lawns, and large iſlands clothed with verdure, and crowned with trees, united with a great extent of water, cannot fail to produce. Upon the river by which the waters of this lake are diſcharged into the bay of Sligo, called by Arrowſmith the Garwoag, ſtands the town of Sligo, the only town of note in the county. There are, however, ports at Ballyſadere and Eſky-bridge, at the mouths of the rivers Arrow and Eſky. Hazlewood, the ſeat of Owen Wynne, eſq. is diſtinguiſhed for its beauty as well as for agricultural improvement, which has been carried here probably to a greater extent than at any other place in Ireland. The linen manufacture has made great progreſs in different parts of the county, eſpecially in the vicinity of Ballymote, where it was eſtabliſhed by the late Hon. Tho. Fitzmaurice.

Sligo, a poſt-town of Ireland, chief town of the county of the ſame name, and a ſea-port, ſituated at the mouth of the river which flows from Lough Gilly to the bay of Sligo. Veſſels of 200 tons can come up to the quays, and the trade of Sligo has been increaſing for many years. When Dr. Beaufort publiſhed, its population was eſtimated at upwards of 8000, the number of houſes being 916. The county aſſizes are held here, and it ſends a member to the imperial parliament. The magiſtrates are a provoſt and town-clerk. A caſtle was built here in 1245, and ſoon after a monaſtery, of which Mr. Archdall has ſaid, "that the few ruins which remain evince its former ſplendour. Three ſides of the cloiſter may ſtill be ſeen, covered with an arched roof: the arches and pillars are of extraordinary workmanſhip, and a few of the pillars are ornamented with ſculpture. The great eaſt window is beautiful, and the high altar, adorned with relievos, in the Gothic ſtyle. The nave is ſpacious, with a paſſage round it in the nature of a gallery, ſupported by ſtone pillars. This great and curious monument of antiquity ſeems to have fallen a prey to the devouring teeth of time, rather than to the hands of man, though Cromwell is ſaid to have injured it." Sligo is 105 miles N.W. from Dublin.

SLIME, in *Agriculture*, a material left by the tides and other waters in different places, which is an uſeful manure. See Ooze.

SLINCK, or Slinghe, in *Geography*, a river of Holland, which joins the Berchel, near Borckeloe, in the county of Zutphen.

SLINE-HEAD. See Slyme-head.

SLING, Funda, a ſtring inſtrument, ſerving for the caſting of ſtones, &c. with the greater violence.

Pliny, l. lxvi. c. 5. attributes the invention of the ſling to the Phœnicians; but Vegetius aſcribes it to the inhabitants of the Balearic iſlands, now called Majorca and Minorca, who were famous in antiquity for the dexterous management of them. Florus and Strabo ſay, thoſe people bore three kinds of ſlings, ſome longer, others ſhorter, which they uſed according as their enemies were nearer or more remote. Diodorus Siculus adds, that the firſt ſerved them for a head-band, the ſecond for a girdle, and that the third they conſtantly carried with them in their hand.

In fight they threw large ſtones with ſuch violence, that they ſeemed to be projected from ſome machine, inſomuch that no armour could reſiſt their ſtroke. In beſieging a town, they wounded and drove the garriſon from the walls, throwing with ſuch exactneſs, that they ſeldom miſſed their mark: this dexterity they acquired by conſtant exerciſe, being trained to it from their infancy, the mothers placing their daily food on the top of a pole, and giving them no more than they beat down with ſtones from their ſlings. This art is ſtill, in ſome meaſure, preſerved by the Minorquin ſhepherds. The invention of the ſling has been erroneouſly aſcribed by ſome writers to the inhabitants of theſe iſlands. Froiſſart (vol. i. c. 85.) gives an inſtance in which ſlings were employed for the Engliſh by the people of Brittany in a battle fought in that province during the reign of Philip de Valois, between the troops of Walter de Mauni, an Engliſh knight, and Louis d'Eſpagne, who commanded 6000 men in behalf of Charles de Blois, then competitor with the earl of Montfort for the duchy of Brittany. According to the ſame author, they were alſo uſed in naval combats. Slings were uſed in 1572, at the ſiege of Sancerre, by the Huguenots, in order to ſave their powder. D'Aubigné, who records this fact, ſays that they were hence called Sancerre harquebuſſes. Slings were conſtructed for throwing not only ſtones, but leaden bullets, and clay-balls, baked or hardened in the ſun. They were made of different materials, chiefly flax, hair, or leather, woven into bands, or cut into thongs, broadeſt in the centre, for the reception of the ſtone or ball, and tapering off gradually towards both ends: with one of theſe ſlings, a good ſlinger would, it is ſaid, throw a ſtone 600 yards. An ancient Icelandic treatiſe, entitled "Speculum Regale," ſuppoſed to have been written about the 12th century, mentions ſlings fixed to a ſtaff.

Sling, in *Surgery*, a well-known bandage for the arm and hand.

Slings, in *Rigging*, ſhort ropes uſed to hang the yards to the maſts, &c. See Slinging.

SLINGELANDT, Peter Van, in *Biography*, was born at Leyden in 1640. He was a laborious diſciple of Gerard Douw, and wrought in the highly finiſhed ſtyle of that maſter; and is as neat in his execution. His pictures, however, do not poſſeſs the reliſh found in thoſe of Gerard, either in compoſition or colour; and they are taſteleſs in deſign. He is ſaid to have been moſt patiently perſevering and induſtrious, employing months and years upon one performance; and never being ſatisfied till he found every individual part imitated, however trivial, of any object which he had choſen to repreſent. His works are often paſſed off for thoſe of his maſter, and of Mieris; and it ſometimes demands a conſiderable portion of connoiſſeurſhip to diſcover the impoſition. He died in 1691.

SLINGER's Bay, in *Geography*, a bay of the Eaſt Indian ocean, on the N. coaſt of New Ireland. S. lat. 3°. E. long. 151°.—Alſo, an inlet of the Pacific ocean, between the iſlands of Ramos and St. Juan.

SLINGING is uſed variouſly at ſea; but chiefly for the hoiſting up of caſks, or other heavy things, with ſlings, *i. e.* contrivances of ropes ſpliced into themſelves at either end, with one eye big enough to receive the caſk, or any thing to be ſlung.

There are other ſlings which are made longer, and with a ſmall eye at each end; one of which is put over the breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoiſt the gun as they pleaſe.

There are alſo ſlings for the yards; which is done by binding them faſt to the croſs-tree aloft, and to the head of the maſt, with a ſtrong rope or chain, that if the tie ſhould happen to break, or to be ſhot to pieces in fight, the yard, nevertheleſs, may not fall upon the hatches.

Slinging *a Man overboard*, in order to ſtop a leak in a ſhip, is done thus: the man is truſſed up about the middle in a piece of canvas, and a rope to keep him from ſinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling-clout, in the other, which he is to beat with all diſpatch into the hole or leak.

SLIP, among *Ship-Builders*, denotes a place lying with a gradual deſcent on the banks of a river, convenient for *ſhip-building;* which ſee.

Slips, maſſes of earth which are apt to ſlip out of the banks of canals, reſervoirs, &c.

Slips, in *Gardening*, ſuch portions of plants as are ſlipped off from the ſtems or branches for the purpoſe of being planted out as ſets. A great number of plants, both of the woody and herbaceous kinds, is propagated by ſlips, which is effected in the woody kinds by ſlipping off ſmall young ſhoots from the ſides of the branches, &c. with the thumb and finger, inſtead of cutting them off with a knife; but there is no material difference, in the ſucceſs or future growth, between ſlips and cuttings, only the former in ſmall young ſhoots is more proper to be ſlipped off by the hand, which, in numerous ſmall ſhrubby plants, will grow; but it is more commonly practiſed in the lower ligneous plants, ſuch as ſage, winter-ſavory, hyſſop, thyme, ſouthernwood, roſemary, rue, lavender, and others of ſlow ſhrubby growths. The beſt ſeaſon of the year for effecting the work, is generally the ſpring and beginning of ſummer, though many ſorts will grow if planted at almoſt any time, from the ſpring to the latter end of the ſummer, as ſhewn in ſpeaking of their culture.

And in performing the work of ſlipping in theſe ſorts, the young ſhoots of but one year's growth, and in many ſorts the ſhoots of the year, ſhould be choſen as growing the moſt readily, even when to plant the ſame ſummer they are produced, eſpecially the hard-wooded kinds: but in the more ſoft-wooded plants, the ſlips of one year's growth will alſo often readily grow; being careful always to chooſe the moderately-growing ſide-ſhoots ſituated on the outward part of the plants, from three to ſix or eight inches long, ſlipping them off cloſe to the branches, and clearing off the lower leaves; then planting them in a ſhady border, if in ſummer, and watered, or ſo as they can be occaſionally ſhaded in hot ſunny weather, eſpecially ſmall ſlips, inſerting the whole two parts of three into the ground, giving occaſional water in dry warm weather, till properly rooted; and then towards autumn, or in the ſpring following, tranſplanting them where they are to remain.

But in planting ſlips of the ſhoots of tender ſhrubby exotics of the greenhouſe and ſtove, many ſorts require the aid of a hot-bed or bark-bed, to promote their emitting roots more effectually, as ſhewn in their reſpective culture; but ſome others of the ſhrubby kinds, ſuch as geraniums, will root freely in the natural earth in ſummer; and many of the herbaceous tribe, producing bottom-rooted offſets for ſlips, as aloes, &c. alſo readily grow, either with or without a hot-bed; but where there is the convenience of hot-beds in which to plunge the pots of ſlips of tender plants, it runs them off more expeditiouſly; and moſt hot-houſe plants in particular require that aſſiſtance. But many ſhrubby plants, growing into large bunches from the root of the ſmall under-ſhrubby kinds, as thyme, ſavory, hyſſop, ſage, &c. as well as theſe of larger growth, as roſes, ſpiræas, raſpberries, and numerous other ſorts, may be ſlipped quite to the bottom into ſeparate plants, each furniſhed with roots, and planted either in nurſery-rows, or at once where they are to remain.

And as to the ſlipping of herbaceous plants, various ſorts multiply by the roots, &c. into large bunches, which may be ſlipped into many ſeparate plants, by ſlipping off the increaſed ſuckers or offſets of the root, and in ſome ſorts by the offſets from the ſides of the head of the plants, and in a few ſorts by ſlips of their bottom ſhoots, as well as of the ſtalks and branches in plants of buſhy growth; but the greater part by ſlipping the roots, as in many of the bulbous-rooted tribe, and numerous fibrous-rooted kinds of plants. The ſlipping of the bulbous plants is performed in ſummer when their leaves decay, the roots being then taken up, ſlipping off all the ſmall offſets from the main bulb, which are generally ſoon planted again in nurſery-beds for a year or two. See Bulbous *Roots*.

In the fibrous-rooted ſorts, the ſlipping ſhould generally be performed in the ſpring or early part of autumn, which may be effected either by ſlipping the outſide offſets with roots, as the plants ſtand in the ground; or more effectually, by taking the whole bunch of plants up, and ſlipping them into ſeveral ſeparate parts, each ſlip being furniſhed alſo with roots, planting them, if ſmall, in nurſery-rows for a year, to gain ſtrength; or ſuch as are ſtrong may be planted at once where they are to remain. See the culture of the different ſorts under their reſpective heads.

SLIPPER. See Plinth.

Slipper, a kind of iron ſledge, or lock, for the uſe of a tram-waggon.

Slipper *Iſland*, in *Geography*, a ſmall iſland in the Eaſt Indian ſea. N. lat. 14° 8′. E. long. 93° 30′.

Slipper, *Lady's*, in *Botany*. See Cypripedium.

SLIPPERY Rock, in *Geography*, a townſhip of America, in the ſtate of Pennſylvania, and county of Mercer, containing 789 inhabitants.—Alſo, a townſhip of Pennſylvania, in Butler county, containing 658 inhabitants.

SLIPPING, among *Gardeners*, the tearing off a ſprig from a branch, or a branch from an arm of a tree. Theſe ſorts of ſlips take root more readily than cuttings. See Slips.

Slipping, in *Rural Economy*, a term uſed among animals to denote abortion in them. Thus, mares are ſaid to ſlip their colts, ewes their lambs, and cows their calves. And it has been ſuggeſted, that cows in calf, by ſmelling to any fleſh, particularly in a putreſcent ſtate, are affected by ſuch a nauſea as to ſtimulate the womb to action, and to eject the fœtus: this is well known in the north of Scotland, where it is particularly guarded againſt. It is obſerved by Mr. Roſs, in the 25th volume of the "Annals of Agriculture," that through the inattention of a game-keeper, there was always horſe-fleſh lying about his yards, and he had many cows which ſlipped calves. It is ſuppoſed, in the "Eſſex Agricultural Report," that bleeding, when one-third or half gone, is a preventative. When it happens, the abortion ſhould be immediately buried, and the cow kept as widely apart as poſſible from the herd, and not receive the bull that goes with them. It is conſidered as certainly infectious.

And in Suſſex it has been ſuppoſed by ſome that the ſlipping of lambs has been cauſed by too free a uſe of rape, as one large ſheep-farmer, ſome years ſince, loſt eighty or ninety in this way; which was ſuppoſed to ariſe from feeding the ewes upon it about the end of the year, though it had been made uſe of before without any bad effect of this kind. The ewes in this inſtance had been hard kept. The ſame circumſtance has alſo taken place among the flocks of other ſheep-farmers. The ſame ſort of crop has, however, been fed on the other ſide of the hedge at the ſame time with the ſame ſort of ſtock without any inconvenience of this nature occurring. It is, therefore, moſt probably to be aſcribed to ſome other unperceived cauſe. Ewes are, however, certainly, from ſome cauſe or other, very ſubject to ſlip their lambs, and of courſe require much care and attention in this reſpect. They ſhould conſtantly be kept in a ſtate of quiet, and free from all ſort of diſturbance for ſome time after the ram has been put to them.

SLIRE, in *Geography*, a town of Norway, in the province of Aggerhuus; 68 miles N.N.W. of Chriſtiania.

SLIT, in *Agriculture*, a crack or cleft in the breaſts of fat cattle, &c.

SLIT-*Grafting*. See ENGRAFTING.

SLIT-*Planting*, among planters, a mode of planting trees in ſmall openings without the whole of the ground being dug out, a ſmall ſlit or opening only being made for each tree. See PLANTING.

SLITTE, in *Geography*, a river of Scotland, which runs into the Tiviot, near Hawick, in Roxburghſhire.

SLOANE, *Sir* HANS, in *Biography*, immortalized as the principal founder of the Britiſh Muſeum, was born at Killaleagh, in the county of Down, Ireland, April 16, 1660. His family is ſaid to have been of Scottiſh extraction; but whatever their ſituation in life might be, they were deſtined to acquire more honour from him, than he derived from them; though, by the education which he received, his circumſtances appear to have been far from indigent. He is ſaid to have been attached, from his youth, to the ſtudy of nature, and this led him perhaps to that of medicine, as a profeſſion. A ſpitting of blood confined him at home for three years, and it was not till his 19th year that he was able to enter on a regular courſe of medical education at London. To this he devoted the four ſucceeding ſeaſons, during which he was introduced to the acquaintance, and even the friendſhip, of Boyle and Ray; great names, whoſe continued favour affords ſufficient teſtimony of the ſucceſsful application of the young ſtudent, to the two ſciences in which they reſpectively took the lead. Sloane proceeded to Paris, in company with Mr. Tancred Robinſon; ſee ROBINSONIA. There he attended the lectures of Tournefort and Du Verney; and he is reported to have taken his medical degrees at Montpellier. This he could hardly have done as a Proteſtant, and therefore we preſume another report to be more correct, of his having graduated at Orange, where poſſibly there might, at that time, be a ſort of Proteſtant univerſity. Returning to London late in 1684, Dr. Sloane became a favourite and inmate of the great Sydenham, who ſeems to have intended taking him by the hand as a phyſician. He was ſoon choſen a fellow of the Royal Society, and in April 1687, entered into the College of Phyſicians. Theſe early advancements afford, as Dr. Pulteney remarks, the ſtrongeſt preſumptions in favour of his knowledge and abilities. Yet he relinquiſhed his domeſtic proſpects, to gratify his ardour for natural knowledge.

A deſire of inveſtigating the natural hiſtory of the Weſt Indies, the appetite for which, among the learned of Europe, had rather been whetted than ſatisfied by ſlight and ſuperficial information, induced Dr. Sloane to embark for Jamaica, in September 1687, as phyſician to the duke of Albemarle, juſt then appointed governor of that iſland. But the death of this nobleman, on the 19th of December, ſoon after their arrival, putting an end to the office of his phyſician, the ſtay of the latter in the new world, which he had been ſo eager to viſit, became abridged by his circumſtances, and neceſſary proſpects in life. He ſnatched fifteen months from theſe calls, and devoted that period, with all poſſible ardour, to the accompliſhment of the real object of his voyage. The Weſt Indies had hitherto been viſited by Engliſhmen, for none but the moſt ſordid purpoſes, and the paſſions, taſtes, and characters of the ſettlers have generally been formed and moulded by the malignant influence of their domeſtic ſyſtem, their luxurious habits, and the natural effects of the climate. Sloane paſſed through this triple ordeal untouched; for he was armed by a love of nature, a thirſt for knowledge, and ſufficient ſcientific acquirements to be ſenſible of the value of what he poſſeſſed, and of what lay within his reach. He made ample collections of natural hiſtory, bringing home from Jamaica, Barbadoes, Nevis, and St. Kitt's, about 800 ſpecies of dried plants, enriched with a moſt abundant ſtore of information reſpecting their qualities and uſes. He arrived in London, May 29, 1689, where he directly reſumed his medical occupations, with which he happily and ſucceſsfully aſſociated his literary purſuits. A fine perſon, and agreeable manners, doubtleſs contributed more to his ſucceſs as a London phyſician, than the ſkill of Hippocrates would have done by its own intrinſic worth. The intereſt of Dr. Sloane ſeems to have lain much in the city. In 1694 he became phyſician to Chriſt's hoſpital, and the next year he married Elizabeth, daughter of alderman Langley, who lived with him near thirty years, dying in 1724. She bore him a ſon and daughter, who died young; beſides two daughters, who carried rich inheritances into the families of Stanley and Cadogan, and who both ſurvived their father.—In 1693 Dr. Sloane was elected ſecretary to the Royal Society, which office he held for nineteen years, to the great honour and benefit of that body as well as himſelf, for he immediately revived the publication of its Philoſophical Tranſactions, which had for ſix years been neglected. He was no leſs attentive to his medical duties in the College, for he projected and eſtabliſhed a diſpenſary for the poor, ſteering ſkilfully through all the difficulties which uſually attend any ſcheme for public benefit, where bodies of men are concerned. The oppoſition he encountered gave riſe to Dr. Garth's celebrated and beautiful poem of the "Diſpenſary," by which alone the memory of theſe conteſts, and of moſt of the parties engaged, is now preſerved. But it is not ſo with Sloane. Unfading wreaths, though not of poetic laurel, adorn his buſt, and his favourite ſcience conſecrates his name in one of the moſt ſtately Weſt Indian plants. See SLOANEA.

In 1696, the ſubject of our memoir publiſhed his Latin Catalogue of the Plants of Jamaica, a cloſely printed octavo of 232 pages. He follows Ray's ſyſtem of arrangement, and is content with referring his ſpecies, as well as he could, like that great writer himſelf in his catalogues of Britiſh plants, to ſome popularly received genus; in which habit and general reſemblance, rather than the ſtructure of the fructification, are his guides. In ſcientific generic diſcrimination indeed, Sloane muſt yield the palm to Plumier and many others. His incompetence in this point, rendered him unfit to eſtimate the talents of Linnæus; when the latter viſited him in 1736, and remarked to Haller, that no botaniſt in England, except Dillenius, underſtood, or cared about, generic characters. But Sloane is nevertheleſs entitled to rank high as a literary botaniſt from his uncommon attention to ſynonyms, by which the little volume in queſtion is rendered almoſt a complete *Pinax* of the plants it contains, and the hiſtory of the ſeveral ſpecies is preſerved, as much as poſſible, from confuſion. That ſuch a work ſhould be free from errors, is impoſſible, but it evinces the learning and diligence of its author. This catalogue was not followed up, till the year 1707, by the publication of the firſt volume of the great work, to which it was a kind of *Prodromus*, and which is entitled "A Voyage to the Iſlands Madera, Barbados, Nieves, St. Chriſtopher's and Jamaica, with the Natural Hiſtory of the Herbs and Trees, four-footed Beaſts, Fiſhes, Birds, Inſects, Reptiles, &c. of the laſt of thoſe iſlands." To this volume is prefixed an introduction, of 154 pages, containing an account of the hiſtory and climate of Jamaica, the manners, domeſtic economy, food, trade, &c. of the inhabitants, and particularly an ample detail of their diſeaſes. The whole is full of curious and inſtructive matter. The body of this volume, compriſing 264 pages, 47 of which are devoted to a journal of the author's voyage, conſiſts of deſcriptions of plants, with every thing that could be got together, relative to their hiſtory or qualities. The whole is illuſtrated by 256 plates, chiefly of plants, each plate often being occupied by ſeveral ſpecies. Theſe were taken from the dried ſpecimens, ſtill extant in the author's herbarium; and are therefore very imperfect as to botanical details, though characteriſtic in their general appearance. It is ſcarcely neceſſary to remark that certain coloured copies which exiſt, are mere impoſitions upon the purchaſer. It is more important to obſerve, that the genera or affinities of the plants are ſometimes widely erroneous, in conſequence of the work having been compoſed from a rather ſuperficial inſpection of dry ſpecimens. Thus *Cardamomum minus, pſeudo-aſphodeli foliis; Cat.* 61; page 166. t. 103. f. 3, of the preſent work, is actually an *Orchidea*, of the genus *Neottia;* whilſt *Orchis elatior latifolia, aſphodeli radice, ſpicâ ſtrigoſâ; Cat.* 119; p. 250. t. 147. f. 2, is, according to the herbarium, an *Alpinia*. The figure however repreſents an *Orchidea*.

The ſtatiſtical part of this book is valuable, but there are ſome remarks relative to the management of ſlaves, which we cannot paſs over, eſpecially as the queſtion of the ſlave-trade ſtill calls for all the vigilance of the Chriſtian moraliſt and politician, to defeat the machinations of its advocates, and ſecret promoters. The following, amongſt others, are Sloane's words. "The puniſhments for crimes of ſlaves, are *uſually* for rebellions burning them, by nailing them down on the ground with crooked ſticks on every limb, and then applying the fire by degrees from the feet and hands, burning them gradually up to the head, whereby their pains are extravagant. For crimes of a leſſer nature, gelding, or chopping off half of the foot with an axe. Theſe puniſhments are ſuffered by them with great conſtancy." The author proceeds as coolly to deſcribe "*uſual*" whipping and other puniſhments, and concludes thus. "After they are whip'd till they are raw, ſome put on their ſkins pepper and ſalt, to make them ſmart; at other times their maſters will drop melted wax on their ſkins, and uſe ſeveral very exquiſite torments. Theſe puniſhments are *ſometimes* merited by the blacks, who are a very perverſe generation of people; and though they *appear harſh*, yet are ſcarce equal to ſome of their crimes, and inferior to what puniſhments other European nations inflict on their ſlaves in the Eaſt Indies, as may be ſeen by Moquet, and other travellers." The author, in palliating theſe enormities, worthy of Spaniſh inquiſitors, and perhaps originally derived from ſome ſuch helliſh ſource, does not inform us whether our Chriſtian Proteſtant miniſters preached againſt them; but we learn from other documents that they durſt not. We know alſo that the parent ſtate, eccleſiaſtical as well as civil, for ages looked on, without interfering; and even at this moment, all the ſtrenuous exertions of the virtuous few, ſupported by the awakened zeal of moſt Chriſtian divines, of every perſuaſion, are ſcarcely able to ſucceed in demoliſhing the root of the evil. Regulations have indeed been made to guard againſt ſome of the above enormities, and the African ſlave-trade has been aboliſhed by law. But let Britons never forget that ſuch things have exiſted, and guard, with all their power and vigilance, againſt a poſſibility of their return. The coolneſs or partiality of Sloane, only proves the callous ſtate of the public mind reſpecting this queſtion, upon which he tried to make himſelf as eaſy as he could. He was, on the whole, a man of good feelings, charitable to the poor, alive to their intereſts wherever they came in his way, and friendly to all improvements in his profeſſion; ſuch as inoculation for the ſmall-pox, and the uſe of the Peruvian bark; both which were combated in his day, even more abſurdly, and no leſs diſhoneſtly, than vaccination is at preſent.

The ſecond volume of Sloane's Jamaica did not appear till the year 1725. By ſome accident, this is much the moſt common of the two, and frequently ſells for a trifle, while both together fetch about twelve guineas. Of this ſecond volume, 187 pages are devoted to the vegetable, and 148 to the animal, kingdom. There is beſides a copious index of 102 pages. About 80 of the plates relate to plants, and 42 to animals. A ſhort account is given of the author's return to England, with the dowager ducheſs of Albemarle; and numerous corrections, or additions, to the firſt volume are ſubjoined. The author frequently refutes his antagoniſt Plukenet in a deciſive ſtyle, but with leſs acrimony than the latter has uſually betrayed. It would be tedious and unprofitable to follow them through all the mazes of their criticiſm, but as far as we have incidentally done this, Plukenet is generally moſt exact. (See PLUKENET.) We muſt not omit to notice, that Sloane liberally allowed Ray to make uſe of his Jamaica manuſcripts, in the third volume of the *Hiſtoria Plantarum*, where the original generic diſtributions of the author, if they merit that appellation, are followed. Though Sloane tells us, in the preface to his firſt volume, that ſome of the plants, with his obſervations upon them, had received the approbation of his illuſtrious friend; it does not any where appear that queſtions of botanical arrangement, or technical diſcrimination, had been particularly diſcuſſed between them. We muſt not therefore lay any defects of this kind to the charge of Ray, to whom the ſcientific botany of the Weſt Indies was nearly an unexplored field, of which Sloane furniſhed him by no means with ſufficient materials for the cultivation; the latter having examined nothing very deeply in this reſpect, and his dried ſpecimens being moſtly inſufficient for the purpoſe.

The collections of natural hiſtory, made by Sloane in his voyage, ſeem to have laid the foundation of that muſeum, which became gradually ſo famous. A brother collector and friend, Mr. Courten, in 1702, left his own acquiſitions to augment it, on condition of the payment of certain debts and legacies, to an amount much below the value of what was thus bequeathed. How ſoon curioſities of art were included in Dr. Sloane's muſeum, or whether ſuch made a part of Mr. Courten's, we know not; but the whole collection was now very conſiderable, and continued increaſing during the long life of its owner, who, the year before he died, reckoned up the articles of natural hiſtory, excluſive of 200 volumes of dried plants, as amounting to more than

30,600. His taſte for collecting was followed by many perſons, nor ſhould his humble imitator, Mr. Salter of Chelſea, the founder of the well-known Don Saltero's coffeehouſe, be altogether deſpiſed. Who can anſwer for the taſte or curioſity that may have been awakened by this humble popular muſeum, or the purſuits and diſcoveries to which it may have led? The writer of this is not aſhamed to acknowledge his own obligations to it at a very early period. The diſcoveries of Sloane in the Weſt Indies were moreover uſeful, in exciting collectors of living plants to enrich their gardens from that novel and fertile ſource, by which all the hot-houſes in Europe profited. Hence the French were led to ſend out PLUMIER, ſee that article; and though at war with England in the year 1708, that nation was generous enough to admit the ſubject of our memoir, with the permiſſion of queen Anne, as one of the eight foreign members of the *Academie des Sciences*. His honours and appointments at home were rapidly increaſing. He was conſulted by the royal family, and created a baronet by king George I. This rank, it is ſaid, had never before been conferred on a phyſician; though ſuch an application of it has ſince been frequent; as being eaſier to the giver, and more advantageous to the receiver, than more ſolid, but leſs brilliant, rewards for court ſervice. Sir Hans became phyſician-general to the army, and in 1719 was elected preſident of the College of Phyſicians, which ſtation he held for ſixteen years; but all his other honours fade before that of the preſidency of the Royal Society, conferred upon him, on the death of ſir Iſaac Newton, in 1727. He reſigned the latter, at the age of fourſcore, in 1740, when he retired to the manor-houſe of Chelſea, which manor he had purchaſed about the year 1720. Here he received the viſits of his ſcientific and other friends, patronized the ingenious, and aſſiſted the diſtreſſed. The worthy George Edwards records, in his Eſſays on Natural Hiſtory, that he ſeldom miſſed drinking coffee with "the good ſir Hans Sloane" on a Saturday, during his retirement of about fourteen years at Chelſea. "He was ſo infirm as to be wholly confined to his houſe, except ſometimes, though rarely, taking a little air, in his garden, in a wheeled chair." Edwards unexpectedly found him in the agonies of death, on the 10th of January, 1753, N.S. at four in the afternoon. He expired at four the next morning, in the 92d year of his age, and was buried, along with his lady, in a vault, at the ſouth-eaſt corner of Chelſea church-yard, where a handſome, and very conſpicuous, monument to his memory ſtill exiſts. His epitaph relates that he died "without the leaſt pain of body, and with a conſcious ſerenity of mind." Edwards ſays, "I continued with him later than any one of his relations, but was obliged to retire, his laſt agonies being beyond what I could bear; though under his pain and weakneſs of body, he ſeemed to retain a great firmneſs of mind, and reſignation to the will of God." Theſe accounts may not be totally irreconcileable. The convulſions of death are "agonies" probably in appearance more than reality; and it is conſolatory to ſee a well-directed mind, even in ordinary caſes, generally ſuperior to them, in a remarkable manner. Sloane was, in every reſpect, prepared to meet them.

The perſon of ſir Hans Sloane was tall and handſome; his manners eaſy, polite and cheerful. He delighted in exhibiting and explaining to ſtrangers, and eſpecially foreigners, whatever he poſſeſſed, and is ſaid to have kept an open table once a-week, for his friends, particularly ſuch as belonged to the Royal Society. That his reception of the great Linnæus was not peculiarly flattering, has often been mentioned with regret; nor can we account for it otherwiſe, than by recollecting that he was not ſufficiently gifted with the taliſmanic power of genius, by which kindred minds diſcover each other, through every diſguiſe of rank, or external appearance. But the principal obſtacle to the free intercourſe of theſe diſtinguiſhed men aroſe, perhaps, from the want of a common language. Linnæus could ſpeak nothing but Latin, and that with the foreign accent. He was moreover, at this time, full of thoſe novel ideas of botanical philoſophy, by which he ſubſequently gave laws to the learned world. Boerhaave, who recommended him with enthuſiaſm to Sloane, could appreciate theſe; but to the latter, as at firſt ſight to Dillenius, they promiſed nothing but confuſion and inconvenience; and though the Oxford profeſſor ſoon looked further into their merits; the opulent patron and collector, who had riſen to eminence by his own means, felt no inclination to go to ſchool to a poor Swediſh ſtudent, hardly ſuperior in his eyes to a working gardener. Few men can be ſerviceable in many different ways. The merits of ſir Hans Sloane were tranſcendant in his own line. He neglected no means, that appeared to him eligible, for promoting literature or ſcience. On purchaſing his great eſtate at Chelſea, he preſented the Apothecaries' company with the fee ſimple of the garden which they had already made there, on a condition, equally beneficial to their fame and to ſcience, that it ſhould for ever continue a *botanic* garden. "He was governor," ſays Dr. Pulteney, "of almoſt every hoſpital in London; and to each, after having given an hundred pounds in his life-time, he left a more conſiderable legacy at his death. He was ever a benefactor to the poor, who felt the conſequences of his death ſeverely. He was zealous in promoting the eſtabliſhment of the colony of Georgia, in 1732; and formed, himſelf, the plan for bringing up the children in the Foundling Hoſpital, in 1739."

Nor was the pen of this active philoſopher idle, amid his other occupations. To particularize even the titles of his papers, printed by the Royal Society, amounting to 35, would lead us too far. However curious and uſeful the contents of moſt of the reſt may be, the laſt in the liſt, on Inoculation, vol. 49. 516, is pre-eminently important, as recording the introduction of that practice into England, and diſplaying the candour, as well as good ſenſe, of the writer, in every thing relative to the ſubject.

It remains for us only to mention the eſtabliſhment of the Britiſh Muſeum, for which the nation is entirely obliged to ſir Hans Sloane. He bequeathed it to the public, on condition of a payment, to his heirs, of 20,000 pounds; a ſum ſaid barely to equal the intrinſic value of the precious metals and gems, of the medals and mineral ſpecimens. Beſides the abundance of natural and artificial curioſities, his library, amounting to 50,000 volumes, of books and manuſcripts, was included in the bequeſt. In collecting theſe books, he is reported to have ſent his duplicates, either to the College of Phyſicians, or the Bodleian library. Parliament having accepted the legacy of Sloane, augmented it with the library of ſir Robert Cotton, and the valuable manuſcripts of the lord treaſurer HARLEY; ſee that article. The whole, with various additions, has been depoſited in the vaſt and maſſy palace of Montagu Houſe, where it is now, in the moſt eaſy manner, and free of expence, acceſſible to the public. Two of the founder's deſcendants are always hereditary truſtees of theſe treaſures, aſſociated by the original act of parliament, or by particular election, with a limited number of the moſt eminent men in the kingdom. For the preſent ſtate of this noble repoſitory, and its more particular hiſtory, ſee MUSEUM, *Britiſh*. Sloane's Works. Pulteney's Sketches of Botany. Aikin's Gen. Biog. S.

Gen. 48. t. 15.)—Claſs and order, *Polyandria Monogynia*. Nat. Ord. *Amentaceæ?* Linn. *Tiliaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five, or more, acute, rather unequal, ſegments. *Cor.* none. *Stam.* Filaments very numerous, above 100, ſhort, inſerted into the downy, fleſhy receptacle; anthers oblong, of two cells, attached lengthwiſe to the filaments. *Piſt.* Germen ſuperior, roundiſh, angular; ſtyle ſimple, awl-ſhaped, longer than the ſtamens; ſtigma nearly ſimple. *Peric.* Capſule large, roundiſh, prickly, of from three to ſix valves, and as many cells, burſting at the top, the partitions from the middle of each valve. *Seeds* two or three in each cell, oblong, obtuſe, involved in a pulpy tunic.

Eſſ. Ch. Corolla none. Calyx of one leaf, inferior, in five or more ſegments. Anthers attached longitudinally to the filaments. Capſule prickly, of from three to ſix valves, and as many cells. Seeds two, with a pulpy tunic.

Obſ. Linnæus ſeems to have been led by the very erroneous opinion of Miller, (who referred this genus to *Caſtanea* or *Fagus*,) to conſider it as probably of his amentaceous order. Juſſieu has far more correctly ranged it with his own genuine *Tiliaceæ*, near *Sparrmannia*. Three ſpecies are now known; fine South American, or Weſt Indian, trees, of which Linnæus was acquainted with the firſt only. His *S. emarginata*, Sp. Pl. 731, taken up from Cateſby's work, without the inſpection of any ſpecimen, is, as Willdenow remarks, no other than *Achras Sapota*. Concerning the reſt, great confuſion, originating with Aublet, is perpetuated by no leſs authority than that of Swartz, followed by Willdenow and Aiton. Juſſieu alſo errs in ſuppoſing the Linnæan *Sloanea* to be *Aubletia*, or *Apeiba*. Such may indeed be the plant of the *Hortus Cliffortianus*, but that of *Sp. Pl.* is certainly Plumier's. We ſhall attempt a corrected view of the ſpecies and their ſynonyms, from authentic ſpecimens.

1. S. *dentata*. Cheſnut-leaved Sloanea. Linn. Sp. Pl. 730. Ait. n. 1. (S. Maſſoni; Swartz Ind. Occ. 938. Willd. n. 2. Sloana amplis caſtaneæ foliis, fructu echinato; Plum. Ic. 240. t. 244. f. 1.)—Leaves toothed; heart-ſhaped at the baſe. Stipulas linear, ſerrated. Calyx deeply divided.—Native of South America and the Weſt Indies. Our ſpecimens were gathered by Maſſon in the iſland of St. Kitt's. Miller is ſaid to have cultivated this plant in the ſtove at Chelſea, but it has not been known to bloſſom in Europe. In its native country this is a lofty *tree*, with round leafy *branches*, finely downy when young. *Leaves* alternate, ſtalked, a foot or more in length, and half as broad, ſmooth, with one rib and many ſtrong tranſverſe veins, rather coriaceous; more or leſs heart-ſhaped at the baſe; the margin diſtantly and rather ſlightly toothed. *Footſtalks* downy, two or three inches long. *Stipulas* near an inch in length, narrow, deeply toothed, almoſt pinnatifid, ſituated in pairs at the baſe of each footſtalk. *Cluſters* axillary, towards the ends of the branches, compound, many-flowered, drooping, not half ſo long as the leaves. *Flowers* green, about three-quarters of an inch wide, conſpicuous for their numerous tufted *ſtamens*. *Anthers*, as well as *germen*, hairy. *Capſule* woody, above an inch in diameter, clothed with very long, rigid briſtles, ſpreading in all directions.

2. S. *grandiflora*. Large-flowered Sloanea. (S. dentata; Swartz Obſ. 213. Willd. n. 1, excluding the ſynonyms, except the following. S. Plumierii; Aubl. Guian. v. 1. 536.)—Leaves toothed; tapering at the baſe. Stipulas triangular-heart-ſhaped, ſerrated. Calyx with ſhallow ſegments.—Gathered in the foreſts of Guiana by Aublet, whoſe ſpecimen is before us. He found it bearing flowers and fruit in November. The *trunk* is forty or fifty feet high, and two in diameter. *Leaves* pointed at each end. *Stipulas* very broad at the baſe, and more ſlightly ſerrated or toothed. *Flowers* almoſt twice as large as thoſe of the preceding; the *calyx* remarkably and eſſentially different, having a broad, hemiſpherical, cup-like baſe, and very wide ſhallow ſegments in the border; whereas the *dentata* has a *calyx* divided nearly to the baſe, into lanceolate, or ſomewhat ovate, taper-pointed lobes. *Capſule* of from three to five cells. *Seeds* one, two, or three in each cell, enfolded in a red ſucculent tunic. The ſpecific character and deſcription given by profeſſor Swartz, cannot be miſtaken; but it is remarkable that he ſhould not have detected Aublet's miſapplication of Plumier's ſynonym. This error is indeed the more pardonable in Aublet, as he was acquainted with but one of theſe two ſpecies, and took it, of courſe, for what Plumier had figured.

3. S. *Aubletii*. Small-flowered Sloanea. Swartz Ind. Occ. 940. (S. ſinemarienſis; Aubl. Guian. v. 1. 534. t. 212. Willd. n. 3.)—Leaves roundiſh, abrupt, entire. Calyx in five deep ovate ſegments.—Gathered by Aublet in the foreſts of Guiana about the river Sinemari, 30 leagues above its mouth, bearing flowers and fruit in November. Swartz ſays it was found by Maſſon in St. Kitt's. The *trunk* is deſcribed as forty or fifty feet high, with a reddiſh, cracked, and wrinkled bark. *Branches* ſlender, finely downy when young. *Leaves* in Aublet's ſpecimen near a foot long, on ſtalks about one-third that length, coriaceous, ſmooth, ſtrongly veined. He deſcribes the *ſtipulas* as being long, broad, and pointed. Theſe we have not ſeen, any more than the *flowers*, which grow in ſhort, ſimple, axillary *cluſters*, and are much ſmaller than either of the preceding. The *ſtyle* in Aublet's plate, as well as his own French deſcription, is repreſented divided into four or five deep ſlender ſegments. The *capſule* is oblong, an inch in length, with four or five cells and as many angles, clothed with long, ſlender, aſcending filaments or briſtles. We ſhould gladly have given the name of *parviflora* to this ſpecies, but we have taken the leaſt exceptionable of thoſe that already exiſt. The *Galibis* call this tree *Oulouqua-Palou*, but nothing is recorded of their applying it to any uſe.

SLOATH, or SLOTH, in *Zoology*, the name of an animal remarkable for its ſlow motion. Of this animal there are two ſpecies. See BRADYPUS.

The *three-toed* ſloth has a blunt black noſe, a little lengthened; very ſmall external ears; ſmall, black, and heavy eyes, with a duſky line from the corner of each; the colour of the face and throat a dirty white; hair on the limbs and body long, and very uneven, of a cinereous brown colour, with a black line along the middle of the back; each ſide, about the ſhoulders, is daſhed with ruſt colour; the reſt of the back and limbs ſpotted irregularly with black; the tail ſhort; legs thick, long, and aukwardly placed; the face naked; and three very long claws on each foot. Pennant.

This creature, which grows to the bulk of a middle-ſized fox, is ſo very tedious in all its motions, that it will be three or four days in climbing up, and coming down a tree, and does not go the length of fifty paces upon even ground in a day. It never ſtirs till compelled by hunger: its food is fruit, or the leaves of trees. Its motion is attended with a very moving and plaintive cry, ſo that beaſts of prey avoid it with horror.

The ſound of its voice ſeems only to expreſs the word *haii*, for which reaſon the Braſilians call him by that name; but he uſually repeats the ſound about ſix times together, deſcending, as if one ſhould ſing *la*, *ſol*, *fa*, *mi*, *re*, *ut*.

Its look is ſo piteous as to move compaſſion, and accompanied with tears. Whatever he takes hold of, he does it ſo ſtrongly, or rather ſo ſtiffly, that he will ſometimes ſleep ſecurely while he hangs at it.

Cluſius, Marcgrave, Piſo, and others, have given deſcriptions of this animal, but they none of them mention the length of his fore-feet; which, according to the animal preſerved in the Muſeum of the Royal Society of London, is double that of the hinder pair.

From the ſhag of his body, the ſhape of his legs, and his having little or no tail, as alſo from the ſlowneſs of his gait, and his climbing up trees as little bears uſe to do, he ſeems to come near the bear-kind, from which he differs chiefly in having but three claws upon a foot.

This creature breeds principally in Florida and Braſil. Grew's Muſ. p. 11.

The *two-toed* ſloth has a round head; ſhort projecting noſe; ears like the human; two long ſtrong claws on the fore-feet, and three on the hinder; long and rough hair on the body, in ſome parts curled and woolly; in ſome, of a pale red above, and cinereous below; in others, of a yellowiſh-white below, cinereous-brown above; it has no tail. This animal inhabits South America, and the iſland of Ceylon. Pennant.

SLOATS *of a Cart*, the under pieces which keep the bottom of the cart together.

SLOB-FURROWING, in *Agriculture*, a particular method of ploughing land.

SLOBNA, in *Geography*, a town of the duchy of Warſaw; 25 miles S. of Kaliſh.

SLOBNICK, a town of the duchy of Warſaw; 24 miles N.N.W. of Poſen.

SLOBODSKAIA, a fortreſs of Ruſſia, in the government of Ekaterinoſlav; 64 miles N.E. of Ekaterinoſlav.

SLOBODSKOI, a town of Ruſſia, in the government of Viatka; 20 miles N.N.E. of Viatka. N. lat. 58° 40′. E. long. 50° 44′.

SLODTZ, RENÈ MICHAEL, in *Biography*, ſurnamed Michael Angelo, a ſculptor, was born at Paris in 1705. He ſtudied under his father, who was a native of Antwerp, after which he went to Rome, and upon his return was admitted a member of the Academy of Paris, where he died in 1764. One of his moſt conſiderable works is the monument of Languet, in the church of St. Sulpice.

SLOE, *Prunus Sylveſtris*, the Engliſh name for the wild plum. See PRUNUS.

The juice expreſſed from the fruit of the ſloe-buſh while unripe, inſpiſſated by a gentle heat to dryneſs, is called German acacia. It differs from the Egyptian moſt remarkably in this property, that it gives out its aſtringency in good meaſure to rectified ſpirit as well as to water, whereas that of the other is not at all diſſoluble in ſpirit.

A conſerve of this fruit has been prepared in the ſhops, by mixing the pulp, preſſed out through a ſieve after the ſloes have been ſteeped in water over the fire, till they are ſufficiently ſoft without burſting, with thrice its weight of double refined ſugar.

In ſome places, the unripe ſloes are dried in an oven, and then fermented with wines or malt liquors, for a reſtringent diet drink in alvine and uterine laxities. The bark, both of the branches and roots, is ſaid to be ſucceſsfully given in intermitting fevers, and it has been recommended by ſome as equal to the Peruvian bark. It is apparently a ſtrong ſtyptic. The watery infuſion of the flowers, ſweetened with ſugar, or made into a ſyrup, is ſaid to be a very uſeful purgative for children. Lewis's Mat. Med.

SLOE-*Worm*, in *Natural Hiſtory*, the name of an inſect found on the leaves of the ſloe, or black-thorn, and ſometimes on thoſe of the garden plum.

This, and a like worm, found on the leaves of the oak, both remarkable for the hairs which cover them, each of which is forked, or divided into two at the ends, are uſually eſteemed caterpillars, but they are in reality animals of a very different claſs: the caterpillar has, at the utmoſt, but ſixteen legs; theſe have twenty-two, and have all the other characters of that claſs of inſects called by the French naturaliſts *fauſſes chenilles*, or baſtard caterpillars.

All the animals of that claſs are very remarkable for the different figure they make after the laſt change of their ſkins; but this is in none ſeen ſo obviouſly, as in theſe two ſpecies: that of the oak is of a greeniſh colour, and its hairs, which are ſo ſtiff that they almoſt deſerve the name of ſpines, are black; that of the ſloe is of a greyiſh hue, and its ſpines longer, and of a deep brown: every one of theſe is, towards the extremity, divided into two, in the manner of the tines of a fork. Theſe give the animal a very remarkable figure, and are caſt off with the ſeveral ſkins, while the new ſkins have others in their place; but in the laſt change, before that into the nymph ſtate, the change made in the creature is ſuch, that it could never be ſuſpected to be the ſame animal by any one, who was not an eye-witneſs of the change.

The creature in this, throwing off its ſkin, becomes perfectly ſmooth, and of a dirty yellowiſh colour, with not the ſlighteſt variegation on it, nor the leaſt appearance even of the remains of the ſpines. In this ſtate it remains till it goes into the nymph ſtate; and from that, after about ſixteen days, it comes out in the ſhape of a four-winged fly. The whole proceſs of the change is the ſame, in the two ſpecies of the oak and the ſloe; but the flies they produce are very different. Reaumur's Hiſt. Inſ. vol. ix. p. 119. See PRUNUS, in *Gardening*.

SLOKUM'S ISLAND, in *Geography*, a ſmall iſland in Barnſtaple bay, near the coaſt of Maſſachuſetts.

SLOMIGRODEK, a town of Auſtrian Poland, in Galicia; 20 miles W. of Lemberg.

SLONEK, a town of the duchy of Warſaw, on the Viſtula; 15 miles N.W. of Ploczk.

SLONIM, a town of Lithuania, in the palatinate of Novogrodek; 32 miles S.S.W. of Novogrodek.

SLONITZ, a town of Bohemia, in the circle of Schlan; 4 miles S. of Schlan.

SLOOP, in *Sea-Language*, a ſmall veſſel furniſhed with one maſt, the main-ſail of which is attached to a gaff above, to the maſt on its foremoſt edge, and to a long boom below; by which it is occaſionally ſhifted to either quarter.

Sloops, ſmacks, barges, and lighters, that paſs through bridges, have the maſt confined in a trunk or wooden cup, above the deck, and faſtened in by an iron ſtrap on the aft-ſide. Some have a ſtrong iron hinge at the heel of the maſt, or a bolt through the heel; ſo that it can be lowered at pleaſure, by the ſtay-tackle eaſing away the fall by degrees. To raiſe the maſt, the fall is brought to the windlaſs, and hove upon, until the maſt is up in its place: the fall is then ſtopped to the windlaſs bitts.

Dutch ſloops are ſmall veſſels, uſed upon the canals in Holland, with one maſt, on which are hoiſted a ſprit-ſail and a fore-ſail, ſet cloſe to the ſtem. There are many fiſhing-boats in Holland, rigged in the ſame way, with the addition of a bow-ſprit and jib, and they are there called "pinks." Their ſails are generally tanned.

Sloop *of War*, is a name given to the ſmalleſt veſſels of war, except cutters. They are rigged either as ſhips or ſnows. See Rate and Ship.

SLOOTEN, or Sloten, in *Geography*, a town of Holland, in the department of Frieſland, capital of Weſtergoe, near a large lake called Slooter-Meer. Its fortifications, conſtructed by the confederates, and afterwards deſtroyed by the Spaniards, have been enlarged by the ſtates of the province, and defended by five baſtions. The magiſtracy is compoſed of four burgo-maſters and three ſenators; 10 miles E. of Bolſwaert. N. lat. 52° 55′. E. long. 5° 35′.

SLOP, Street, in *Agriculture*, that ſort of moiſt ſloppy ſubſtance, which is raked, ſweeped, and ſhovelled up from the ſtreets of large towns, for uſe as manure. It is a kind of material which is much made uſe of in this way, in the vicinity of the metropolis, in the neighbourhood of Mancheſter, and of ſeveral other places, where it is collected in large quantities. Near the firſt of theſe places the bargemen on the river are ſaid, in the agricultural report of the county, to convey to and deliver the ſlop of the ſtreets at any diſtance which is capable of being reached in one tide, at the price of about four guineas for ſeventeen or eighteen cart-loads, each load conſiſting of nearly two tons weight. This is called *cold* manure, in contradiſtinction to that of the ſtable littery ſort, which is denominated *hot* manure, and delivered at the expence of one guinea more.

Slop of this kind is alſo ſent from the different wharfs, by the barges, on the river Lea canal, which carry about thirty tons, or fifteen cart-loads; and delivered, as far as the towns and villages at about thirteen miles diſtance, for four pounds.

At Mancheſter, the value of this ſort of manure, from almoſt nothing, has increaſed to a very conſiderable ſum, in the courſe of the laſt twenty-five years.

Moſt other large towns might afford vaſt ſupplies of manure of this nature, and be of great advantage to agriculture; while, at the ſame time, they would derive an increaſed revenue from it. At preſent much neglect takes place in this reſpect, in many places. See Manure.

SLOPAN, in *Geography*, a town of Poland, in Volhynia; 52 miles N.E. of Lucko.

SLOPE-Holes, in *Canals*, are holes or marks made in the points E and L (*Plate* I. *Canals*, *figs.* 14 and 15.), to direct the navigators, or workmen, where to begin to cut or dig the ſides of a canal.

SLOPES, are ſuch parts of the ground as have been dug or left ſloping, as G I and K P (*Plate* I. *Canals*, *figs.* 3 and 6.) Some alſo denominate the ſides of the canal, as C B and H I, (*figs.* 14 and 15.) the ſlopes.

SLOPING Alley. See Alley.

Sloping *Banks*, in *Rural Economy*, the ſhelving borders of rivers and ſea-ſhores, which are highly uſeful and neceſſary for ſecuring and protecting them againſt ſtrong floods and tides. The more ſlow and gradual ſuch ſlopes are made, the more beneficial they will be in giving ſafety to ſuch banks. See River-*Banks, Securing of*, and Embankment.

SLOP-ROOM, in *Ship-Building*, an apartment on the orlop, appointed for the purſer to keep the ſhip's ſlops in.

SLOT, in *Agriculture*, a term uſed to ſignify any broad, flat, wooden bar.

Slot, in the *Sportſman's Language*, a term uſed to expreſs the mark of the foot of a ſtag, or other creature proper for the chace, in the clay or earth, by which they are able to gueſs how long the creature has been gone by, and which way he went. The ſlot, or treading of the ſtag, is very nicely ſtudied on this occaſion. If the ſlot be large, deep printed in the ground, and with an open cleft, and, added to theſe marks, there is a large ſpace between mark and mark, it is certain that the ſtag is an old one. If there be obſerved the ſlots, or treadings of two, the one long, and the other round, and both of one ſize, the long ſlot is always that of the larger beaſt.

There is alſo another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore-feet, whereas thoſe of the young ones do.

Old ſtags alſo are long-jointed, and they never tread double or falſely, as the young ones do, becauſe the tendons, that hold the joints of their feet, are ſtronger; but the feet of the young ones are ſometimes forced, for want of theſe ſtrong ſinews, to turn away double.

It is to be obſerved alſo, that there is a great difference between the ſlot of a ſtag or hart, and that of a hind; for there is no hart of the ſecond head ſo young, but that he leaves a larger and wider ſlot than the hind, excepting when the hinds are big with young, for on that occaſion their claws will open as wide as thoſe of the hart.

Another method of knowing the age of a ſtag is by his fumets, though ſome general rules are to be known, before any thing can be judged from this article. Theſe are, that in April and May they caſt their fumets as it were in cakes; and in June and July they caſt them in thin, long, and large crotels; and from thence to the end of Auguſt they hold the ſame form and ſize; but they are in this laſt month always hard and knotty. In all theſe caſes, the largeſt and longeſt fumets are eſteemed to be the marks of the largeſt and oldeſt ſtags. If they have been diſturbed, or if they have received any hurt, they uſually caſt them ſharp at one end, and dry. This alſo is conſtantly the caſe, when their new horns are juſt grown to their hardneſs, and they rub them againſt the trees to get off the cracked membranes, which were the velvetings in their firſt ſtate.

There is always alſo a difference between the fumets of the morning and thoſe of the evening: thoſe made at night, when they go to relief, are better digeſted, and conſequently moiſter than thoſe made in the morning; becauſe having taken their reſt all day, there is a more perfect digeſtion made than can be in the night, as they are, during that time, ſeeking food.

There are alſo ſeveral other ways of judging of the growth and ſize of a ſtag, as by his carriage, or bearings, according to the huntſman's phraſe; that is, according to the breaking of the tender branches of trees which he makes with his horns in paſſing through. When the boughs are found bruiſed and broken very high, and to a good width, there is no doubt of his being an old one; but this judgment is not to be made in the months of March, April, May, and June, becauſe their horns are at that time either wholly wanting, or they are young and velvety. The height of the creature's entries into the woods is alſo another mark of his ſize; for the old ones are always proud and ſtately, and go in erect, but the young ones will creep.

The older the ſtag is, the ſooner he goes to fray, and the larger are the trees he chooſes for this uſe; the young ones go later into it, and always chooſe the weaker and lower trees. Notwithſtanding that, after the ſixth year, the age is not certainly known by the horns, as there is, after this time, no increaſe in the number of their branches; yet a probable gueſs may be made from their being all thicker and more robuſt, and the tops more open.

Slot, *Drawing on the.* See Drawing.

SLOTH, in *Zoology.* See Sloath.

SLOUGEA, in *Geography,* a town of Tunis, on the north ſide of the Mejerdah; 12 miles N.E. of Tuberſoke.

SLOUGH, a hamlet in the pariſhes of Upton and Stoke Pogeis, and hundred of Stoke, county of Buckingham, England, is 21 miles W. from London, and 1 mile N. of Eton. This place is ſeated on the great weſtern road, and has long been the reſidence of Dr. Herſchel, the celebrated aſtronomer, who manufactured here ſome of the largeſt reflected teleſcopes ever known. One of theſe, forty feet in length, ſtill remains in the garden attached to his houſe; and by the uſe of this very powerful inſtrument, the doctor has made ſeveral important diſcoveries in the planetary ſyſtem. A particular account of this teleſcope, with eighteen engravings, is publiſhed in the Philoſophical Tranſactions for 1795. Beauties of England, vol. i. by J. Britton and E. W. Brayley, 1801. Lyſons's Magna Britannia, vol. i. 4to.

Slough, a deep rut or hole in a road or carriage-way. The caſt ſkin of a ſnake, the damp of a coal-pit, and the ſcar of a wound, are alſo called by the ſame appellation.

Slough *of a wild Boar,* is the bed, ſoil, or mire, in which he wallows, or in which he lies in the day-time.

Slough-*Silver,* in *Old Writers,* a rent paid in ſome places in lieu of certain days work in harveſt, heretofore reſerved to the lord from his tenants.

SLOUTH, or Slought, in *Hunting,* is uſed for a company of ſome ſorts of wild beaſts: as, a ſlouth of bears.

SLOW Fevers. See Fever.

Slow *Pulſe.* See Pulse.

Slow-*Worm,* the Engliſh name of the *cæcilia,* or *anguis fragilis* of Linnæus, called alſo the *blind-worm,* and by ſome the *deaf adder,* which, in the Linnæan ſyſtem, is a ſpecies of the *anguis* or ſnake; the *cæcilia* being a diſtinct genus of ſerpents. See Serpentes.

It is diſtinguiſhed from all our ſnakes by its ſmallneſs, and by the ſhape of its tail, which runs out a great way beyond the anus, and yet is blunt and conſiderably thick at the end.

The colour of the back is cinereous, marked with ſmall lines compoſed of minute black ſpecks; the ſides are of a reddiſh caſt; the belly duſky; both marked like the back; the tongue is broad and forky; the teeth ſmall, but numerous, and the ſcales ſmall. It is ſlow in its motion, and inoffenſive in its nature.

Theſe ſnakes lie torpid in the winter, and are ſometimes found in vaſt numbers twined together.

It reſembles the viper in its manner of producing its young, which are brought forth alive.

Dale, from Geſner, gives an account of theriaca being prepared of this ſerpent and treacle water, for a ſudorific in the plague. James.

SLUCH, or Slutch, in *Agriculture,* a term often applied to ſignify a ſoft liquid muddy ſort of material, found in different ſituations where water ſtagnates.

SLUCHAU, or Tshluchow, in *Geography,* a town of Pruſſian Pomerelia; 44 miles S.S.W. of Dantzig.

SLUCK, or Sluckz, a town of Lithuania, in the palatinate of Novogrodek, in which are three Greek churches, one for Roman Catholics, one for Lutherans, and one for Calviniſts; 68 miles E.S.E. of Novogrodek. N. lat. 52° 50′. E. long. 27° 33′.

SLUDGE, in *Agriculture.* See Sluss.

SLUDKA, in *Geography,* a town of Ruſſia, in the government of Perm; 8 miles S. of Obvinſk.

SLUDS, a term uſed by the miners in Cornwall for half-roaſted ores.

SLUE, *To,* is to turn any cylindrical or conical piece of timber about its axis, without removing it. This term, in ſea-language, is generally applied to the movement by which a maſt or boom is turned about, in its cap or boom-iron.

SLUG. See Limax.

Slug, in *Agriculture* and *Gardening,* a deſtructive animal of the ſnail kind, which is highly miſchievous in the field, as well as the garden, by eating off the young ſtems of tender plants. There are ſeveral different kinds of theſe little animals. The white and brown leathery kind often even deſtroy the ſtrong ſtems of young cabbage, and other ſimilar plants. The deſtruction of them has been ſuggeſted to be effected by the uſe of tar-water, ſprinkled over the ground; and alſo by having recourſe to lime, in the preparation of the land for ſuch crops. They conceal themſelves in the holes and crevices, only making their appearance early in mornings and late in the evenings. The white ſlug or ſnail is likewiſe very deſtructive to young turnip crops, by riſing out of the holes of the ſoils, on wet and dewy mornings and evenings. Rolling the ground with a heavy implement, before the ſun riſes, has been adviſed as a means of deſtroying them in theſe caſes.

Slugs of this ſort are likewiſe very deſtructive, in ſome diſtricts, to the roots of corn crops, during the day-time, in the early ſpring months, while they lie concealed in the ground, by eating and devouring them; and by coming out in the evenings, and during the night-time, to commit ravages on the blades, and other parts above the ground. Numbers of them are ſometimes met with upon the ſame plant, and they may eaſily be extirpated and removed from the land by the above practice, while they are at work, eſpecially in moon-light ſeaſons, and any further injury to the crops be guarded againſt. Warm moiſt weather is always a great encouragement to their coming out of their hiding-places; and advantage ſhould conſtantly be taken of it for their extermination, as they ſuddenly retire under ground during the time of cold.

The ſtrong lands of other places are occaſionally much infeſted with them in the pea, bean, and rye crops and ſtubbles, as well as clover roots, when a wheat crop is put in upon them. The ſlugs, in ſome caſes, are of about half an inch in length, having their backs of a blueiſh caſt in the ſkin part, and their under parts wholly of a white appearance.

A mixture of ſulphur and lime, made ſo as to be conveniently applied, has been found to be highly deſtructive of ſlugs in general.

The uſe of lime-water has lately been adviſed as an excellent and cheap mode of deſtroying ſlugs in gardens, as well as fields, in the ſecond volume of the Tranſactions of the Horticultural Society of London. It is found to be far preferable, in this intention, to quick-lime, which is liable to become too ſoon ſaturated with moiſture, and rendered ineffectual. The manner of employing the water is after it has been newly made from ſtone lime, by means of hot water poured upon it, to pour it through the fine roſe of a watering-pot over the ſlugs, which have been collected by means of pea-haulm, or ſome other ſimilar ſubſtance, laid down on the ground in portions, at the diſtance of about a pole from each other. In proper weather, the ſlugs ſoon collect in this way, in great numbers, for ſhelter as well as to get food. When a boy takes up the ſubſtance, and by a gentle ſhake leaves the whole of the ſlugs on the ground, another perſon then pours a ſmall quantity of lime-water on them, and the boy removes the haulmy material to ſome intermediate place, in order that the ſame practice may be repeated. By perſevering in this method for a little while, the whole of the ſlugs may be deſtroyed, as the leaſt drop of the water ſpeedily kills them. This practice, it is ſuppoſed, will be found highly beneficial in the flower-garden, as by watering the edgings of box, thrift, or other kinds, the ſlugs will be killed with certainty, even when the weather is moiſt.

The application is conſidered ſimple, the effect certain, and the expence trifling, whether in the garden or the field; a few pots only being required, in the latter caſe, to the acre, which can be made with a very ſmall quantity of lime. And the labour is not of any material conſequence, ſo that the whole charge will not, it is imagined, exceed five ſhillings the acre.

SLUICE, a frame of timber, ſtone, or other matter, ſerving to retain and raiſe the water of a river, &c. and, on occaſion, to let it paſs.

Such is the ſluice of a mill, which ſtops and collects the water of a rivulet, &c. to let it fall, at length, in the greater plenty, upon the mill-wheel: ſuch alſo are thoſe uſed as vents or drains to diſcharge water off land. And ſuch are the ſluices of Flanders, &c. which ſerve to prevent the waters of the ſea overflowing the lower lands, except when there is occaſion to drown them.

Sometimes there is a kind of canal incloſed between two gates or ſluices, in artificial navigations, to ſave the water, and render the paſſage of boats equally eaſy and ſafe, upwards and downwards: as in the ſluices of Briare in France, which are a kind of maſſive walls built parallel to each other, at the diſtance of twenty or twenty-four feet, cloſed with ſtrong gates at each end, between which is a kind of canal, or chamber, conſiderably longer than broad; in which a veſſel being incloſed, the water is let out at the firſt gate, by which the veſſel is raiſed fifteen or ſixteen feet, and paſſed out of this canal into another much higher. By ſuch means a boat is conveyed out of the Loire into the Seine, though the ground between them riſe above one hundred and fifty feet higher than either of thoſe rivers.

The ſluice of a canal has generally a ſliding-board or door, but ſometimes folding or double doors moving on hinges, uſed to ſtop or let go water at pleaſure.

Sluice-gates ſometimes ſignify the lower gates of a lock, from the paddles or ſluices that are uſually fixed in them.

Sluices are made different ways, according to the uſe for which they are intended: when they ſerve for navigation, they are ſhut with two gates, preſenting an angle towards the ſtream; when they are made near the ſea, two pair of gates are made, the one to keep the water out, and the other in, as occaſion requires. In this caſe, the gates towards the ſea preſent an angle that way, and the others the contrary way; and the ſpace incloſed by thoſe gates is called the *chamber*. When ſluices are made in the ditches of a fortreſs, to keep up the water in ſome parts, inſtead of gates, ſhutters are made ſo as to ſlide up and down in grooves; and when they are made to raiſe an inundation, they are then ſhut by means of ſquare timbers let down in culliſes, ſo as to lie cloſe and firm.

The word ſluice is formed of the French *eſcluſe*, which Menage derives from the Latin *excluſa*, found in the Salic law in the ſame ſenſe. But this is to be reſtrained to the ſluices of mills, &c.; for as to thoſe ſerving to raiſe veſſels, they were wholly unknown to the ancients.

In *Rural Economy*, a ſluice is very convenient in many caſes. It ought to be ſtrongly framed in deep waters, particularly where a great height is neceſſary, ſo as to ſtand firm and immoveable againſt the ruſhing of heavy bodies; for a ſmall ſtrain makes it leaky, and a ſmall thing will occaſion this, unleſs ſufficiently guarded by proper abutments. Larch, green elm, or willow, are the beſt ſorts of timber to be always in water; but heart of oak, for the purpoſe of ſtanding above it, in wet and dry. The importance of ſluices is extremely evident on many occaſions, as when a preſſing neceſſity demands the diſcharge of a great quantity of water, either the expenſive mode of engines muſt be recurred to, the bank cut, or a ſluice drawn. If the bank be cut, the paſſage is interrupted, and there remain the trouble and charge of removing the earth, and re-embanking; but a ſluice vents the ſuperfluous water, without the leaſt inconvenience or charge. Their utility in many caſes of drainage and embankment, as well as irrigation, is alſo very great and indiſpenſable.

SLUIDENAIA Kopi, in *Geography*, a town of Ruſſia, in the government of Irkutſk. N. lat. 52° 42′. E. long. 113° 44′.

SLUIN, a town and fortreſs of Croatia, on the Korana; 34 miles S. of Carlſtadt. N. lat. 45° 15′. E. long. 16° 8′.

SLUIS. See Sluys.

SLUM, a town of Pruſſia, in Pomerelia; 8 miles S. of Marienburg.

SLUPCA, a town of the duchy of Warſaw; 15 miles S.S.E. of Gneſna.

SLUPECZ, a town of Poland, in the palatinate of Sandomirz; 16 miles N. of Sandomirz.

SLUPICK, a town of Holland; 3 miles N.E. of Goude.

SLUR, in *Muſic*, a mark like the arc of a circle, drawn from one note to another, comprehending two or more notes in the ſame or different degrees. If the notes are in different degrees, it ſignifies that they are all to be ſung to one ſyllable; for wind inſtruments, that they are to be made in one continued breath; and for ſtringed inſtruments, that are ſtruck with a bow, as a violin, &c. that they are made with one ſtroke. If the notes are in the ſame degree, it ſignifies that it is all one note, to be made as long as the whole notes ſo connected; and this happens moſt frequently betwixt the laſt note of one line, and the firſt of the next; which is particularly called *ſyncopation*.

SLUSE, René Francis, in *Biography*, an eminent mathematician, was born of a noble family at Viſe, a ſmall town in the biſhopric of Liege, in 1622. He was educated for the church, and was canon of St. Lambert in that city, was appointed abbot of Amaz, and grand chancellor and counſellor to the biſhop and prince; all which offices he retained with high reputation till his death in 1685, in the 63d year of his age. He was a man of great learning, not only in the particular line of his profeſſion, but in juriſprudence, and even in medicine. He was eminently ſkilled in the Greek, Hebrew, Arabic, and other Oriental languages; and on that account was employed by the pope, during his reſidence at Rome, and after his return to Liege, in tranſlating Greek, Armenian, and other writings. He was an excellent mathematician, and furniſhed ſome papers for the Tranſactions of the Royal Society, of which he was elected a member. As an author his principal work is entitled "Meſolabium et Problemata Solida," 4to. In this work M. Sluſe rendered great ſervice to the mathematical ſciences, by ſimplifying ſome parts of the analyſis of Des Cartes, which had engaged the attention of many eminent geometricians. He is author of a method, by which any ſolid equation being propoſed, it may be conſtructed in an infinite variety of ways, by means of the circle and any one of the conic ſections. He firſt gave a ſpecimen of this method in the above work, but concealed the analyſis till he publiſhed the ſecond edition of it in 1688. An account of it is given by Montucla, in his "Hiſtory of the Mathematics." This author remarks, that Sluſe's Geometrical Miſcellanies, which appeared in this ſecond edition, do honour to the author, and afford a proof of the great progreſs he had made in analyſis. Beſides the work here referred to, he wrote two letters on the ſuperiority of the Latin to the French language, which were tranſlated from the Latin to the French, and publiſhed with the letters of M. Le Laboureur, in which a contrary opinion is maintained, under the title of "Avantages de la Langue Françoiſe ſur la Langue Latin." Sluſe's Papers in the Philoſophical Tranſactions are, 1. "A ſhort and eaſy Method of drawing Tangents to all Geometrical Curves," vol. vii. 2. "A Demonſtration of the ſame," vol. viii. 3. "On the Optic Angle of Alhazen."

SLUSS, or SLUDGE, in *Agriculture*, a word applied to mud or mire. It is ſometimes written *ſluſh*.

SLUTCH. See SLUCH.

SLUTER, MATTHEW, in *Biography*, a patrician of Hamburgh, was born in that city in 1648. He ſtudied juriſprudence at Jena and Altdorf, and made a tour through Germany and Holland. In 1673 he took the degree of doctor at Roſtock. He practiſed the law in the chancery court of Güſtrau, and afterwards viſited France, and other places, from which he returned in 1679. He continued his profeſſional labours in his native place, where, in 1701, he became ſyndic, and in two years afterwards a member of the council. He died in 1719, in the 72d year of his age. Beſides various works on juriſprudence, he was author of one entitled "Sciagraphia Bibliothecæ Patrum maximæ," which was added to the "Propylæum Hiſtoriæ Chriſtianæ" of his brother Severus Walter. Sluter was a curious obſerver of the weather, and wrote an illuſtration of a treatiſe on Meteorology, publiſhed at London in 1690, by William Cock of Edinburgh. In this tract the author endeavours to eſtabliſh a connection between the changes of the weather and the heavenly bodies; and the object of Sluter in his illuſtration and commentary was to prove the truth of his theory from experience. The German edition of Cock's Meteorology was publiſhed at Hamburgh in 1691. Our author likewiſe publiſhed tracts, entitled "Cauſes of the ſevere Winter and continual Storms in the Years 1694 and 1695;" and "Indications of the Aſpects from the Years 1696 to 1703."

SLUYS, or L'ECLUSE, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Eſcaut. The place contains 1415, and the canton 4479 inhabitants, on a territory of 92½ kiliometres, in 6 communes. This was formerly one of the beſt ports on the coaſt of Flanders, and capable of conveniently receiving 500 veſſels; but it has been ſo much deteriorated, that it can now accommodate only ſmall veſſels. Its ancient name was "Lammens Vliet." It belonged to the comtes of Nevers, but was obtained in exchange for Bethune of William, comte of Namur, by Philip the Hardy, duke of Burgundy, who ſurrounded it with walls in 1385. In 1495 Philip de Cleves, lord of Ravenſtein, revolted againſt Philip le Beau, and retired to Sluys, which was beſieged by Albert, duke of Saxe, and after four months it ſurrendered. The city having taken part with the Hollanders, was beſieged by the prince of Parma in 1587, and the Engliſh garriſon was compelled to ſurrender, but upon honourable terms. Until the year 1604 it remained in the poſſeſſion of Spain; but being beſieged by prince Maurice of Naſſau, it was obliged to ſurrender after a defence of four months. The town is furniſhed with ſluices, by which the whole country may be inundated; and hence it derives its name. After ſeveral changes of maſters, the garriſon was ſummoned by the French republicans in July 1794; and on the 25th of Auguſt, after a gallant defence, became priſoners of war; 18 miles N.E. of Oſtend. N. lat. 51° 20′. E. long. 8° 14′.

SLYBZE. See SLEBEZE.

SLYME-HEAD, a cape on the weſt coaſt of Ireland, in that part of the county of Galway, called Ballinahinch. N. lat. 53° 24′, according to Beaufort, but 53° 29′, according to Arrowſmith's late map. W. long. 10° 12′.

SLYPE, a town of France, in the department of the Lys; 5 miles N.N.W. of Menin.

SLYRET, a town of Norway, in the province of Aggerhuus; 80 miles N. of Chriſtiania.

SMACK, is a ſmall veſſel only rigged as a ſloop, or hoy, and uſed in the coaſting or fiſhing trade; or as a tender in the king's ſervice. See SLOOP.

SMALAND, or SMOLAND, in *Geography*, a province of Sweden, about 100 miles long and 60 broad, formerly governed by its own kings; and, for a conſiderable time, included in Eaſt Gothland, and ſubject to the ſame laws. It is ſaid to have derived its name Smaland, *i. e.* ſmall parcels of land, from the circumſtance of its having been overſpread with woods and waſtes, which reſtricted the culture to a few intervening ſpots. Smaland is mountainous; nevertheleſs ſome parts are ſo improved by cultivation as to be very fertile, and its paſtures in particular are excellent, and of courſe profitable to the graziers. This province comprehends large foreſts of beech and other trees; and alſo ſilver, copper, and iron mines, a great quantity of iron-ore being found at the bottom of the lakes. A vein of gold-ore has likewiſe been diſcovered in Smaland. The chief employment of the inhabitants is agriculture, mining, and graziery. The articles of trade are alſo planks, beams, maſts, tar, pot-aſh, iron, grain, cattle, butter, cheeſe, fleſh, bacon, tallow, hops, and fiſh. In this province are 21 lakes, and its chief towns are Calmar, Wexio, and Jonkioping.

SMALBROKE, RICHARD, in *Biography*, an Engliſh prelate, was fellow of Magdalen college, Oxford; and in 1723 he was advanced to the biſhopric of St. David's, from whence he was tranſlated, in 1730, to Lichfield and Coventry. He died in 1749. He was diſtinguiſhed by a vindication of the miracles of Chriſt againſt Woolſton.

SMALCIUS, VALENTINE, a celebrated writer in favour of Unitarianiſm, was born in Thuringia, and died at Cracow, in Poland, in 1622. His principal work was "A Treatiſe on the Divinity of Chriſt," written in the Latin language, and printed in 1608.

SMALKALDEN, in *Geography*, a river of Germany, which runs into the Werra, 12 miles W. of Smalkalden.

SMALKALDEN, or *Schmalkalden*, a large, thriving, and populous town of Germany, in the county of Henneberg, on a river of the ſame name. In its vicinity are ſalt-pits, and mines of iron and ſteel. The Proteſtant princes have had ſeveral meetings in this town, preparatory to the league which was concluded here in 1531, and to their confirmation of the theological articles drawn up by Luther, which have given this town conſiderable celebrity in eccleſiaſtical hiſtory; 27 miles N.N.E. of Schweinfurt. N. lat. 50° 47′. E. long. 10° 40′.

SMALL *of an Anchor*, is that part of the ſhank, next under the ſquare, or anchor.

SMALL-*Craft*, in *Sea-Language*. See CRAFT.

SMALL *Fruits*, in *Gardening*, a term applied to thoſe which are produced by different plants of a low ſhrubby growth, as thoſe of the gooſeberry, currant, and raſpberry kinds, when grown alone, and in a ſeparate ſtate. See Standard *Fruit-Trees.*

Small *Key*, in *Geography*, a ſmall iſland in the Eaſt Indian ſea. N. lat. 10° 37′. W. long. 247° 16′.

Small *Oat*, in *Agriculture*, a name applied to a particular kind of black grain of this ſort, in ſome places. It is hardy, and capable of being grown with ſucceſs on poor land of the chalky and other kinds. Other names are alſo given to it; and there is a ſort of oat termed the ſmall ſhort, or ſmall ſhorts, in the farmer's language. See Oat.

Small *Point*, in *Geography*, a cape on the coaſt of Maine, forming the eaſt point of Caſco bay.

Small *Repeat*. See Repeat.

Small *Sallad Herbs*, or *Sallading*, in *Gardening*, are ſuch young tender herbs as are made uſe of through the year, for the purpoſe of furniſhing ſallads. For this uſe, ſeveral young ſeedling herbs of a warm nature are in requeſt to mix with the larger principal ſallad herbs, as lettuces, endive, and celery, in order to improve their flavours and wholeſome qualities. The ſorts moſtly in uſe are creſſes, muſtard, raddiſh, rape, and turnep; alſo ſometimes cabbage-lettuce for winter and early ſpring uſe; all of which, for this uſe, are in perfection when quite young, that is, while not more than a week, or ten or twelve days old, whilſt they remain moſtly in the ſeed-leaf, being then cut up cloſe to the ground for uſe; for, being moſtly of a warm reliſh, in which conſiſts their chief excellence for winter and ſpring ſallads, if ſuffered to grow large, and run into the rough leaf, they become of a diſagreeable, ſtrong, hot taſte; but when uſed as above, they are exceedingly criſp and tender, with an agreeable warm flavour. For the purpoſe of ſallading, theſe plants may be obtained young at all times of the year, in the ſpring and ſummer in the open ground, and in winter under the ſhelter of frames and glaſſes, and occaſionally on hot-beds. This ſort of ſallading is procured by ſowing the ſeeds of the different plants at different times, throughout the whole year.

Winter and Spring Culture.—In the winter and ſpring it may be raiſed either in hot-beds, or in the open borders, and, according as it may be required, early or late; but when it is required as early as poſſible, it muſt be ſown in hot-beds, under frames and lights, &c. or in a bed or border of natural earth under glaſſes. The ſowing ſhould be made on hot-beds any time in December, January, or February; and where a conſiderable ſupply is daily required, it may be continued ſowing every week or fortnight, in hot-beds, till March, or during the cold weather, for which a moderate hot-bed of dung ſhould be made for one, two, or more garden-frames; but only half a yard or two feet depth of dung, according to the temperature of the ſeaſon, as the heat is only required to bring up the plants quickly, and forward them a week or two in growth, placing a frame directly thereon, and moulding the bed all over with light rich earth, five or ſix inches thick, making the ſurface level and ſmooth: when, if it is to be forwarded as much as poſſible, directly ſow the ſeed, which may be done either in drills as ſhallow as poſſible, about two or three inches broad, and flat at the bottom, and three inches aſunder, ſowing the ſeeds of each ſort ſeparately, and very thick, ſo as almoſt to cover the ground, only juſt covering them with earth; or, to make the moſt of the bed, it may be ſown all over the ſurface, previouſly ſmoothing it lightly with the back of the ſpade, the different ſorts ſeparately, and all very thick; and after preſſing them all even and lightly down with the ſpade, covering them very thinly with earth, by ſifting over as much light mould as will only juſt cover the ſeed; and as ſoon as the ſowing is performed in either method, putting on the lights. The ſeeds ſoon come up, as in two or three days, or leſs, being careful at this time to give vent to the ſteam ariſing in the bed, as well as to indulge the plants with plenty of free air daily, either by tilting the lights in the back or front, according to the temperature of the weather, or by drawing the lights a little down, or taking them quite off occaſionally in mild days at firſt; for the hot-bed being yet new, there will be a conſiderable ſteam ariſing; and the ſallading coming up very thick, unleſs due vent be given to paſs off the ſteam, and admit freſh air, the plants will be apt either to burn or fog, (as the gardeners term it,) and mould off as faſt as they come up. Such hot-beds, however, as are not freſh made, do not require this precaution; but in new-made beds it muſt be ſtrictly obſerved, till the ſallading is all fairly come up, and as long as the ſtrong ſteam continues. The plants will moſtly be fit for uſe in a week, or ten or twelve days, from the time of ſowing the ſeed.

But in order to have a proper ſucceſſion, the ſowing in the hot-beds ſhould be repeated every week or fortnight during the cold weather; the ſame hot-bed ſometimes retaining its heat, will admit of two ſowings, by ſowing again as ſoon as the firſt crop is gathered: however, to obtain a regular ſupply daily, it is neceſſary to continue making freſh hot-beds occaſionally. Where only a ſmall quantity may be wanted at a time, and there is the convenience either of cucumber and melon hot-beds, or a hot-houſe, &c. ſome ſeed of each ſort may be ſown in pots or boxes, and placed in theſe hot-beds, or the ſtove, juſt to bring up the plants fit for uſe. And where there are not frames and glaſſes, hand or bell-glaſſes may be uſed, or the bed be arched over with low hoop-arches, in order to cover it with mats every night, and in bad weather.

Where, however, there are no hot-beds, in cold weather, early in the ſpring, part of a warm border, or a bed of light earth in a ſunny ſituation, may be prepared for garden-frames and lights, hand-glaſſes, &c. raiſing the ground ſomewhat to the ſun; and having dug it, and raked it fine, ſow the ſeed as above, covering it lightly with earth; and having ſet on the frames and glaſſes, the ſeeds will ſoon come up, and the ſallading be ready a conſiderable time ſooner than in the open ground.

Culture in the full Ground.—From about the end of February, or beginning of March, according to the forwardneſs or mildneſs of the ſeaſon, ſmall ſallading may be ſown in the open ground, repeating the ſowings every week or ten days; the firſt ſowing being performed on a warm border; continuing the ſowings in that ſituation till the beginning or middle of April, when it may be ſown in any of the open quarters, and in which the ſowings may be repeated weekly, or once a fortnight, as required; but according as the hot weather approaches, ſowing in a ſomewhat ſhady ſituation. The ground for each ſowing in the different ſituations ſhould be properly dug, and the ſurface raked ſmooth and even.

Theſe ſowings are moſtly made in ſhallow drills, which ſhould be drawn with a ſmall hoe, either with the corner, or held edgeways downward, horizontally, drawing the drills along evenly, as ſhallow as poſſible, and flat or level at bottom, at three or four inches aſunder, in which the ſeeds ſhould be put evenly all along the bottom, each ſort ſeparately, and very thick, covering them in evenly with the fineſt of the mould, not more than a quarter of an inch deep; or if the ſmaller ſeeds are but juſt covered, it is ſufficient;

for when ſown very thick, if deeply covered with mould, the plants do not riſe regularly. In theſe early ſpring ſowings, on cold nights, and in all bad weather, it is proper to cover the ground, both before and after the plants begin to riſe, with large mats; which will be better, if ſupported on low hoop-arches, or ranges of pegs ſtuck in the ground juſt high enough to ſupport the mats a little from the earth, by which a more effectual as well as forward crop is produced.

But in the latter ſowings, when dry warm weather commences, it is proper to give occaſional waterings. It is likewiſe ſometimes neceſſary, where the ſurface of the ground becomes cruſted from wet, &c. as the plants riſe thick, to ſlightly bruſh over the ſurface with the hand or a ſoft broom, ſo as to reduce the ſurface mould a little, and promote their coming up.

Summer Sowings.—When the ſowings are practiſed in ſummer, they ſhould be made more frequently, and the ground be kept watered occaſionally, both before and after the plants are come up.

Autumn Sowings.—The ſowings may be continued in the open ground all September and October, alſo occaſionally in November, in mild ſeaſons; and until towards the middle of October, they may be made in any open ſituations; but from the middle or latter end of October, and in November, they muſt be on warm ſouth borders, performing the ſowings as above; and in cold nights, beſtowing a covering of mats or hand-glaſſes, &c. repeating the ſowings every week or ten days, or a fortnight, as required.

In gathering young ſallading, it ſhould be cut carefully cloſe to the ground, while quite young; in performing which, a large pair of ſciſſors is very convenient.

In order to have good ſeed, ſome plants ſhould be preſerved annually for the purpoſe.

SMALL *Stones*, among *Jewellers*, denote diamonds under the weight of a carat.

SMALL-*Work*, is uſed to denote the ſtar and ſhell-facets of diamonds.

SMALLAGE, in *Botany*, a ſpecies of *apium;* which ſee.

Smallage grows naturally by the ſides of ditches, in many parts of England, and is therefore rarely cultivated in gardens: it is biennial, and flowers in Auguſt. Care ſhould be taken to diſtinguiſh ſmallage from the poiſonous water-hemlock, which grows naturally in the ſame places with it: the latter has its leaves deeply divided, quite to the pedicle, into three long narrow ſharp-pointed ſegments; whereas thoſe of ſmallage are only ſlightly cut into three roundiſh obtuſe ones.

The root is that part which was formerly uſed in medicine: it is about the thickneſs of a thumb, whitiſh, fibrous, of a warm taſte, and a fragrant ſmell; and was reckoned one of the five greater openers of the ſhops. It was reputed to be grateful and detergent, to promote urine, and to diſlodge gravel; and it was alſo recommended in diſorders of the breaſt, and for promoting expectoration.

The freſh roots, eſpecially when produced in their native watery places, are ſuppoſed to participate, in ſome degree, of the ill quality of thoſe of the hemlock kind, and to be particularly hurtful to epileptic perſons and pregnant women.

Its ſeed was alſo of the number of the leſſer hot ſeeds, and was thought to poſſeſs greater virtues as a carminative and aperient than the root; its leaves having been given in decoction, or the expreſſed juice of them in nephritic complaints. The root was greatly recommended againſt ſuppreſſions of the menſes, and of the lochia, and was even ſaid to be alone a remedy for the king's evil; but this wants proof.

Smallage is now wholly exploded from the materia medica.

SMALL-POX, in *Medicine*, the *Variola* of authors, a highly contagious and formidable eruptive fever, which occurs in general but once during the life of any individual, and is diſtinguiſhed by the appearance of puſtules on the ſkin, on the third or fourth day of the fever.

As we have already entered into a brief detail of the little that is known reſpecting the origin and early propagation of ſmall-pox, (ſee INOCULATION,) it may be ſufficient to mention in this place, that it is generally believed that this contagious malady exiſted in China and Hindooſtan, perhaps for ſome centuries previous to its appearance in Europe; but that there are no very authentic records of its travelling to the weſt, until the period of the ſiege of Mecca by the Abyſſinians, in the year 572, when it deſtroyed the invading army. Alexandria being at that time the great mart of Indian commerce, was ſoon infected with the contagion, and the firſt deſcription of the diſeaſe was given by Ahron, a phyſician of that city, in the beginning of the following century. From that time it accompanied the Arabs or Saracens in their progreſſive expeditions, and Europe was contaminated by their invaſions of Spain, Sicily, Italy, and France in the eighth century. Previous to this period, it is generally believed that this deſtructive peſtilence was unknown in Europe. This is principally inferred from the ſilence of all the ancient phyſicians, Greeks and Romans, who have left us accurate deſcriptions of many of the diſeaſes, with which we are now familiar, but who have not deſcribed the ſtriking and peculiar ſymptoms which characterize this ſevere and often fatal malady. Some authors, however, and not without a ſhow of probability, have maintained that ſuch an inference is not ſtrictly deducible from this circumſtance. For the ancients were apt to confound every ſpecies of fatal fever under the term *peſtilence*, and were miſled, by their hypothetical doctrines about the four humours, to make no diſtinctions from a view of the ſymptoms. Some of the ancient plagues, and particularly that of Athens, deſcribed by Thucydides, were manifeſtly not *the plague* properly ſo called, but were connected with extenſive ſores and eruptions on the ſkin. (See PLAGUE.) It has been urged, too, that in a fragment of the works of one Herodotus of Rome, preſerved by Aëtius, there is a deſcription of various fevers, accompanied by eruptions, in which the ſmall-pox appears to be diſtinctly included. It is remarkable, too, that the firſt Arabian phyſicians, even Ahron of Alexandria, do not mention the diſeaſe as a new malady, but ſpeak of it as one familiarly known; and Rhazes refers to Galen, as having mentioned many of its ſymptoms. The evidence in ſupport of this opinion is certainly very imperfect, and ſcarcely ſufficient to build a controverſy upon; nor is it of any farther importance than as an object of curious inquiry.

All that relates to the hiſtory and practice of *inoculation* (which, indeed, ſhould now be ſuperſeded by vaccination) has been alſo detailed in the article already referred to. At preſent, therefore, our object is to give only the medical hiſtory of ſmall-pox, as it occurs in the caſual, or, as it is often called, the natural way; deſcribing, firſt, its ſymptoms, with the prognoſtics, and various tendencies of the diſeaſe, and afterwards the beſt methods of treatment.

The term *variola*, which is of modern origin, is ſuppoſed to be derived from *vari*, which are ſmall inflamed tumours of the face, occurring about the period of puberty, and noticed firſt by Celſus under that appellation. The words *pock*, *pocks*, and *pox*, from the Anglo-Saxon *pocca*, ſignifying a pouch or pocket, and applicable to any puſtule or puſtular diſeaſe, were appropriated early to this formidable malady; and the epithet *ſmall* was ſubſequently added to diſtinguiſh it from a ſtill more recent diſeaſe, the *lues venerea*, to which the ſame appellation was applied.

Several varieties of the ſmall-pox have been noticed by different writers, but they may be all included under the two principal forms, which were ſo ably pointed out by Sydenham, and which ſince his time have been commonly recognized under the appellations of the *diſtinct* and the *confluent* ſmall-pox. Although originating from the ſame contagion, and not differing from each other eſſentially, they exhibit a different ſeries of ſymptoms, purſue a ſomewhat different courſe, and require a different mode of treatment, and therefore it is convenient to treat of them ſeparately.

1. *Of the Diſtinct Small-Pox:—Variolæ Diſcretæ.*—In this form of the diſeaſe, the eruptive fever is moderate, and not eaſily diſtinguiſhed from an ordinary attack of common inflammatory fever. It generally begins about mid-day, with a chillineſs and ſhivering, accompanied by a conſiderable languor, and drowſineſs, which are ſoon followed by a great heat, pains in the head and back, ſickneſs at the ſtomach, with a ſoreneſs or preſſure in that part, and in adults, eſpecially if they are kept in bed, with a great diſpoſition to perſpiration. In children the ſweating does not occur; but they are liable to frequent ſtartings from their ſlumbers, and on the third day are ſometimes affected with one or two fits of convulſion. Sydenham conſidered this ſymptom as rather favourable; having obſerved that it was commonly ſucceeded by an eruption of a large and mild ſmall-pox. On the evening of the third, or the morning of the fourth day, the eruption appears, and gradually increaſes during the fourth and fifth days, ariſing firſt on the face, and ſucceſſively on the inferior parts, ſo as to be completed over the whole body on the laſt-mentioned day. With the appearance of the eruption, the febrile ſymptoms abate, and nearly or altogether ceaſe on the following day, with the completion of the eruption. This appears firſt in ſmall red ſpots, ſcarcely eminent, but which, by degrees, riſe into minute pimples, which are ſeparate and diſtinct from each other, and generally not very numerous. The day after their appearance, a ſmall veſicle, containing a clear or ſlightly whey-coloured fluid, ſhews itſelf on each of the ſpots. For two days theſe veſicles increaſe in breadth only, and there is a ſmall depreſſion in their centre. As they extend, they continue to be ſurrounded with an exactly circular inflamed margin, which, when the puſtules are numerous, covers the greater part of the intervening ſkin, and diffuſes ſomewhat of a damaſk hue over the ſpaces between the puſtules. Under the touch they are hard, and rather painful, and give the impreſſion of ſmall round ſeeds under the cuticle to the finger; a circumſtance which tends to diſtinguiſh them from the veſicles of chicken-pox, which feel like ſmall ſeeds flattened by preſſure.

About the *eighth* day, the eruption is elevated into ſpheroidal puſtules; and if theſe are numerous, the increaſe of their ſize and the fullneſs of the ſurrounding parts occaſion a conſiderable ſwelling of the whole face, and eſpecially of the eye-lids, which are ſo diſtended as entirely to cloſe the eyes, and often ſhine like an inflated bladder. Sometimes, where numerous puſtules fix upon the eye-lids, the blindneſs comes on before the eighth day. The eruption now aſſumes a whiter appearance; for, as the diſeaſe proceeds, the matter in the puſtules becomes by degrees more opaque, and at length, as the ſuppuration increaſes, of a yellowiſh colour. A ſimilar progreſs is obſerved in the hands, but a little later; ſo that when the face is becoming rough and yellow, the extremities are becoming ſmoother and whiter. On the *eleventh* day the ſwelling of the face is much abated, and the inflammation diminiſhed: the puſtules are now at their height, and ſeem quite full. On the top of each a darker ſpot appears; and at this place the puſtule, on the eleventh day or ſoon after, is ſpontaneouſly broken, and a portion of the matter oozes out; in conſequence of which the puſtule is ſhrivelled and ſubſides, while the matter oozing out dries, and forms a cruſt upon its ſurface. Sometimes very little of the matter oozes out, but remains in the puſtule, becoming thick, and even forming a hard little ſcab. After ſome days, generally about the fourteenth or fifteenth, both the cruſts and the hardened puſtules fall off, leaving the ſkin on the points which they covered of a brown red colour; and it is only after many days that theſe red marks are effaced. The diſtinct ſmall-pox ſeldom leaves any pits in the ſkin; but in ſome caſes, where the matter of the puſtules has been more liquid, the cruſts formed by it are later in falling off, and the points which they covered undergo ſome degree of ulceration, which partially deſtroys the ſubſtance of the ſkin, and produces a ſmall excavation or pit. Sydenham and Cullen aſcribe this erroneouſly to the deſquamation which enſues.

As the eruption is ſucceſſive, ſo the maturation on the body and extremities follows the ſame courſe as above deſcribed, but a little later. On the tenth and eleventh days, as the ſwelling of the face ſubſides, a ſwelling ariſes in the hands and feet, which again ſubſides, as the puſtules come to maturity. In the puſtules of the hands and arms, indeed, the matter is frequently abſorbed; ſo that at the height of the diſeaſe, theſe puſtules appear as empty veſicles.

When the puſtules on the face are numerous, ſome degree of feveriſhneſs appears on the tenth and eleventh days, but it ceaſes again after the puſtules are fully maturated, or continues only in a very ſlight degree till the laſt puſtules on the feet have finiſhed their courſe. In the diſtinct ſmall-pox this ſecondary fever is never conſiderable, and ſeldom continues longer than the period juſt mentioned. Under the ſame circumſtances, an abundant crop of puſtules on the face, ſome uneaſineſs in the throat, and a hoarſeneſs of voice, occur about the ſixth or ſeventh day, and a thin fluid is poured out from the mouth. Theſe ſymptoms increaſe with the ſwelling of the face; and the diſcharges from the mouth and throat becoming thicker and more viſcid, are more difficultly ejected. Some difficulty of ſwallowing alſo occurs; ſo that liquids taken in to be ſwallowed are frequently rejected, or thrown out by the noſe. But all theſe affections of the fauces abate as the ſwelling of the face ſubſides.

Some varieties of the diſtinct ſmall-pox have been deſcribed by different authors under ſpecific appellations, ſuch as the *contiguous*, the *coherent*, the *warty*, &c. ſmall-pox (ſee Walker's Inquiry into the Small-pox, chap. viii. and Roe's Treatiſe on the Natural Small-pox, chap. i.); but theſe are merely more violent degrees of the diſeaſe, partaking more or leſs of the character of the confluent ſpecies, and requiring to be treated accordingly.

2. *Of the Confluent Small-pox.*—This form of the ſmall-pox follows a ſimilar courſe with the preceding ſpecies, but the ſymptoms of every ſtage are more violent, and ſeveral of the circumſtances are alſo different. The eruptive fever eſpecially is much more violent; the pulſe is more frequent, ſharp, and contracted; the head-ache, and the pain and anxiety at the præcordia, the ſickneſs and vomiting, are more ſevere; the coma is more conſiderable, and there is frequently a delirium. In adults there is leſs diſpoſition to perſpiration than in the other ſpecies, and ſometimes a diarrhœa occurs; and in children epileptic fits are frequent on the firſt days of the diſeaſe, and ſometimes prove fatal before any eruption

appears, or they uſher in a very confluent and malignant ſmall-pox.

The eruption appears more early than in the benign ſmall-pox; commonly early on the third day, or on the evening of the ſecond, and ſcarcely ever ſo late as the fourth day; except, as Sydenham remarks, in a few rare caſes, where it appears to be delayed by ſome violent ſymptom, ſuch as an acute pleuritic or rheumatic pain, or a violent pain in the ſtomach, with ſickneſs and vomiting, which manifeſtly indicate the confluent and dangerous nature of the forthcoming diſeaſe. The eruption too is often preceded by an extenſive erythematous efflorеſcence, like a commencing eryſipelas; and ſometimes it comes out in little irregular cluſters, like the meaſles, conſiſting of many crowded red points or pimples. The pimples are always moſt numerous on the face, and at the ſame time ſmaller and leſs eminent. The little veſicles which form on the tops of the pimples, appear ſooner than in the diſtinct ſpecies, and while their diameters extend, they do not retain a circular form, but are of very irregular figures. Many of them run into one another, forming a flat irregular ſurface, ſo that the face very often appears to be covered rather with one extended veſicle, than with a number of puſtules. And when there is any diſtinct ſeparation of the puſtules, they do not riſe to a ſpheroidal form, but remain flat, and their circumference is not bounded by an inflamed margin, the part of the ſkin that is free from puſtules being commonly pale and flaccid, and not exhibiting the damaſk hue of the diſtinct ſmall-pox. The fluid included within the puſtules changes about the eighth day from a clear to an opaque appearance, being firſt whitiſh and now browniſh, but never acquires the yellow colour and thick conſiſtence that appear in the mild ſpecies.

In the confluent ſmall-pox, the ſwelling of the face, which is ſometimes abſent from the diſtinct ſpecies, but is generally preſent when the puſtules are numerous, never fails to appear, and it comes on more early, and ariſes to a greater degree, ſometimes annihilating every appearance of the features. It abates, however, on the tenth day, and on the eleventh ſtill more. At this time the puſtules or veſicles, or rather the extended pellicle, which from the eighth day had become rough and brown, is ruptured; and, ſhrivelling, pours out a fluid, which concretes into brown or black cruſts, which do not fall off for many days, even till after the twentieth day; and, in conſequence of the ulceration which takes place under them, pretty certainly leave the ſurface of the face conſiderably pitted. On the other parts of the body, and on the extremities, eſpecially the hands and feet, ſtill more than on the trunk, the puſtules of confluent ſmall-pox are larger and more diſtinct than upon the face; but they never acquire the ſame maturity and conſiſtence of pus as in the properly diſtinct kind.

The confluent ſmall-pox is attended by two other ſymptoms of conſiderable importance, the one in adults, the other in children. The former is ſalivation, or exceſſive ſecretion of ſaliva, which never fails to accompany the confluent form of the diſeaſe in grown perſons, and is ſometimes ſeen in a ſlight degree in the diſtinct kind. It ſometimes begins as ſoon as the eruptions appear; and ſometimes not till a day or two after. The ſaliva is for ſome time thin and copious, and eaſily diſcharged, having very much the appearance of the ptyaliſm excited by mercury, except that it does not ſmell ſo offenſively; but about the eleventh day it becomes thick and more viſcid, and is expectorated with great difficulty. The patient is very thirſty, and coughs while he attempts to drink, expelling the liquor through his noſtrils. The affection of the throat is alſo generally aggravated at the ſame time. The ſalivation often ceaſes after the eleventh day, about which time the hands commonly ſwell (or at leaſt, Sydenham ſays, ought to do ſo); but ſometimes, after a complete ceſſation for a day or two, it returns again.

In children, a diarrhœa occurs frequently in the place of the ſalivation; but it does not ſeize them ſo early as the ſalivation attacks grown perſons. Whenever it begins, however, unleſs it be checked by art, it attends the diſeaſe to its termination.

In the diſtinct ſmall-pox, as we have already ſtated, the fever commonly ceaſes with the completion of the eruption on the fifth day; but it is not ſo in the confluent ſpecies. In the latter, the febrile ſymptoms only ſuffer a remiſſion at the time of the eruption, which continues to the period of complete maturation, that is, to the eleventh day, in the latter part of which day it is often renewed with conſiderable violence, conſtituting what has been called the *ſecondary fever*, which is the ſource of much danger, and is of various duration. The pulſe quickens, the heat of the body increaſes greatly, much thirſt, with great anxiety and reſtleſſneſs, ſevere head-ache, ſhort and confuſed ſlumbers, delirium, and ſometimes coma, enſue. Theſe ſymptoms, indeed, are often ſo ſudden and violent, being accompanied alſo with ſuppreſſion of the ſalivation, and a difficulty of breathing and of deglutition, that, if nothing has been done to alleviate the early inflammatory action, death ſoon follows. Whence Sydenham ſpeaks ſo often about the danger of the eleventh day. In other caſes, however, this fever is protracted to the fourteenth and ſeventeenth days, and ſometimes even later, and yet terminates fatally. In ſome inſtances, theſe ſevere forms of confluent ſmall-pox are accompanied by ſymptoms of great malignancy or putreſcency, as it has been called: purple ſpots, or *petechiæ*, appear in the interſtices of the ſkin between the puſtules; and ſometimes ſmall black ſpots, ſcarcely ſo large as pins' heads. ariſe on the top of the eruptions in different places: or a diſpoſition to gangrene under ſerous veſicles ſhews itſelf: or laſtly, various ſpontaneous hæmorrhages take place from the internal parts, as from the kidneys and bladder, whence bloody urine is diſcharged; or from the lungs, in bloody expectoration; and ſometimes from the inteſtines, in bloody ſtools.

From a conſideration of the preceding detail of the various circumſtances which accompany the different forms and ſtages of the ſmall-pox, the degree of danger under the various ſymptoms, and the probable event in particular caſes, may be eſtimated. The following points of prognoſis will be obviouſly inferred. In general, the more exactly the diſeaſe retains the form of the diſtinct kind, it is the ſafer; and the more it approaches or takes the form of the confluent kind, it is the more dangerous. It is only, indeed, when the diſtinct kind exhibits a great number of puſtules in the face, which are contiguous or coherent, that it is attended with any danger: for it muſt be obſerved, that it is chiefly from the crowd of puſtules on the face, and not from thoſe on the body, that the danger of the diſeaſe is to be apprehended. Particular ſymptoms will enable us to anticipate particular occurrences. Thus, if the previous or eruptive fever be very violent in its attack, and be accompanied with great proſtration of ſtrength, anxiety, and lowneſs of ſpirits, with ſevere head-ache, weeping and redneſs of the eyes, great pains in the back, a burning heat of ſkin, and a quick hard pulſe;—the occurrence of a confluent eruption may be expected. The more early the eruption, the more danger is to be anticipated; but a retardation of the eruption beyond the fourth day, alſo implies a probability of a confluent diſeaſe. The more gradual the eruption of the puſtules, the more favourable; provided the time of their riſing be not protracted beyond the uſual limits by diarrhœa, pain, or depreſſing paſſions. The more diſtinctly ſuppuration takes place about the eighth day, and the more roſy the interſtices around the puſtules, the leſs danger is to be apprehended. A ſudden ceſſation of the ſwelling of the face about the eleventh day, and the non-appearance of that ſwelling about the eighth day, when the puſtules are very numerous, are indicative of great danger; as are alſo a ſudden ſuppreſſion of the ſalivation in adults, and of the diarrhœa in children, at the former period; eſpecially if the hands and feet have not exhibited any ſwelling about that time. If, in the diſtinct ſmall-pox, convulſions occur in children after the eruption is come out, or after incruſtation has taken place, death commonly enſues; or, if the patient ſurvives, a paralyſis of ſome of the limbs often remains. The diſcharge of pale and clear urine, with frequent urging to paſs it, in any period of the diſeaſe, denotes great danger.

On the other hand, regular gentle ſweats, and a free diſcharge of urine, which depoſits a ſediment, are favourable ſymptoms in every ſpecies of ſmall-pox. If, in the turn of the confluent ſmall-pox, the puſtules, which were before pale and flat, ſhould acquire a redneſs or damaſk-roſe colour round their baſes, and ſuppuration come on, the patient generally recovers.

When the ſmall-pox attacks women in a ſtate of pregnancy, it is attended with conſiderable danger, and commonly produces miſcarriage or premature labour. It has been a queſtion among pathologiſts, whether the connection between the child in the womb and the mother was ſuch as to admit of the infection of the former with the ſmall-pox under theſe circumſtances. Whatever hypothetical differences might exiſt upon this topic, experience has proved that ſuch infection often takes place in the fœtus *in utero*, though not invariably. It would appear, too, that the child is not affected at the ſame moment with the mother, but ſoon afterwards by ſubſequent infection. For, in a caſe related by Dr. Laird, a woman in the fifth month of her pregnancy paſſed through a ſevere ſmall-pox, which commenced about the end of Auguſt: ſhe felt the motion of the child till the month of October, on the 28th of which month ſhe was delivered of a child, which was thought to be of ſix months' growth, and which had been dead ſome days. "On the back, ſhoulders, and ſide, and particularly about the upper part of the thighs, where the integuments were perfectly ſound, there were ſeveral puſtular elevations, with central depreſſions, ſtrikingly characteriſtic of the appearances which diſtinguiſh ſmall-pox. The fœtus was placed in the muſeum of Guy's Hoſpital, and ſtill diſtinctly exhibits the characters of the eruption." See Edinburgh Med. and Surg. Journal, for April, 1807.

A ſtill more extraordinary circumſtance, in reſpect to the infection of the child in the womb, occaſionally occurs; namely, the production of ſmall-pox in the child, in conſequence of the mother's expoſure to the contagion, although the latter may have been prevented from ſuffering the diſeaſe herſelf, by having previouſly undergone that diſeaſe, or the cow-pox, and therefore eſcapes the influence of the infection. Dr. Jenner relates the following caſe, which came under his obſervation, in the inſtance of a lady in London. "A few days previous to her confinement, ſhe met a very diſguſting object, whoſe face was covered with the ſmall-pox. The ſmell and appearance of the poor creature affected her much at the time; and though ſhe mentioned the circumſtance on her return home, ſhe had no idea that her infant could ſuffer from it, having had the ſmall-pox herſelf when a child. During a few days after its birth the little one ſeemed quite well; but on the fifth day it became indiſpoſed, and on the ſeventh the ſmall-pox appeared. The puſtules, which were few in number, maturated completely. Dr. Croft, who attended her, being curious to know the effect of inoculation from one of the puſtules, put ſome of the matter into the hands of a gentleman eminently verſed in that practice, which produced the diſeaſe correctly. Mrs. W. was not ſenſible of any indiſpoſition herſelf from this expoſure, nor had ſhe any appearance of the ſmall-pox." Another caſe is mentioned by Dr. Jenner, in which the child *in utero* was infected with ſmall-pox contagion, and born with the eruption upon it, five weeks after the mother had been vaccinated, and a month after ſhe had been expoſed to the contagion of ſmall-pox from three of her children. Whence, as Dr. Jenner juſtly infers, it is obvious, "that the ſmall-pox virus may affect the human frame, even to its inmoſt receſſes, although apparently ſecured from its effects, and yet give no evidence of its preſence by exciting any perceptible diſorder." (See Medico-Chirurgical Tranſactions, vol. i. p. 272. Alſo, Van Swieten, Comment. ad Aphor. 1381; and Dr. Mead's Diſcourſe on Small-pox, chap. iv.) Dr. Mead ſtates the following analogous fact. "A certain woman, who had formerly had the ſmall-pox, and was now near her reckoning, attended her huſband in the diſtemper. She went her full time, and was delivered of a dead child. It may be needleſs to obſerve, that ſhe did not catch it on this occaſion; but the dead body of the infant was a horrid ſight, being all over covered with the puſtules; a manifeſt ſign that it died of the diſeaſe before it came into the world."

Though the confluent ſmall-pox ſhould not be immediately fatal, yet the more violent kinds are often followed by a morbid ſtate of the body, under which various diſagreeable and dangerous complaints ariſe. Whether theſe conſequences may be aſcribed, with Dr. Cullen, ſometimes to an acrid matter, generated by the preceding diſeaſe, and depoſited in different parts, and ſometimes to an inflammatory diatheſis produced, and determined to particular organs of the body, is a theoretical inquiry, which we are not diſpoſed to puzzle ourſelves and our readers by purſuing. It is manifeſt, in general, that the conſtitution is often left in a ſtate of great debility; does not thrive under the ordinary nutrition; and in many caſes exhibits a great tendency to ſcrofulous inflammation, eſpecially of the glandular ſyſtem, to chronic derangements of the lungs, meſentery, and other viſcera, and to various local affections of the ſkin, membranes, and bones. Another ſeries of evils, which the confluent ſmall-pox is liable to inflict, is the various degrees of injury and deſtruction which it occaſions in the organs of ſenſe, eſpecially in the eyes and ears. Deafneſs of one or both ears, and the loſs of ſight in one or both eyes, is no uncommon reſult of this formidable malady. It appears indeed, from the records of the humane "Inſtitution for the indigent Blind," that a very large proportion of all that claim its protection have been blinded by the ſmall-pox.

Cauſes of Small-pox, and of its Varieties.—The only exciting cauſe of ſmall-pox is the ſpecific contagion, generated in the puſtules of the diſeaſe itſelf. In what manner, or at what period of time, this great depopulator of the human race was generated, or what phyſical circumſtances concurred to give it exiſtence, hiſtory affords us no means of aſcertaining. The abſurd ſpeculations of the Arabian phyſicians, reſpecting the origin of the diſeaſe from ſome contamination of the fœtus with the menſtrual impurities of the mother, deſerve no notice. The obvious origin of a diſeaſe, (ſo analogous to ſmall-pox, as to ſuperſede the influence of its contagion on man,) from a diſeaſe of the ſkin of the heels of a horſe, of which the cow-pox has recently afforded an example, has led ſome ſpeculators to the more probable conjecture, that the poiſon of ſmall-pox may have been communicated to the human from ſome domeſticated animal. The camel has been ſuggeſted: but it was forgotten, that, though Arabia was the country from which Europe probably received the contagion; yet that that country appears to have received it from the moſt eaſtern nations, by its early commerce, among whom it had previouſly exiſted from remote antiquity. (See Moore's intereſting "Hiſtory of the Small-pox," 1815.) At preſent we can only attend to the operation of this contagion, and inveſtigate its qualities from the effects which it produces.

It is evident, that the contagion of ſmall-pox is capable of being communicated, and of exciting the diſeaſe in others, both by the actual contact of the fluid of the puſtules, and the dried cruſts, and by diffuſion in a ſtate of ſolution in the atmoſpheric air. It may be alſo fixed and adherent to various ſubſtances, ſuch as woollen, linen, cotton, and other materials of clothing, as well as to wood, and other articles of furniture; from which alſo it may exhale in a ſtate of vapour. Whence a perſon may be infected, without actual contact either of the diſeaſed, or of *fomites*, that is, of infected ſubſtances. We have already ſtated, however, at great length, under the article CONTAGION, (which ſee,) the proofs and experiments by which it is rendered manifeſt, that the influence of this, and probably of moſt other contagions, by diffuſion in the atmoſphere, is limited to a very ſmall diſtance from the ſource of infection. We refer eſpecially to the experiments of Dr. O'Ryan, of Montpellier, upon that ſubject, which are related in the article juſt referred to. See alſo Dr. Haygarth's Plan for the Extermination of Small-pox in Great Britain.

One property of the contagion of ſmall-pox, which it poſſeſſes in common with the contagion of meaſles, ſcarlet fever, and chicken-pox, but which does not belong to the contagion of gaol-fever, or typhus, nor to that of the plague, nor to the chronic contagious maladies, ſyphilis, and ſcabies, is its power of affecting the conſtitution *but once during the life of the individual.* The occurrence of the diſeaſe, under the mildeſt or the moſt ſevere form, equally renders the body incapable of receiving the diſeaſe again. This is the general fact; but in regard to none of theſe eruptive fevers can it be affirmed, without many exceptions: and the ſmall-pox preſents many anomalies in this reſpect. The extreme rarity of a ſecond attack of ſmall-pox was noticed by the Arabian writers; and their admiſſion of ſuch a fact would ſcarcely be admitted as a proof of its occurrence, ſince they deemed the ſmall-pox and meaſles to be but varieties of the ſame diſeaſe. They attempted to explain the occaſional recurrence of the diſeaſe upon their abſurd theory of its origin, ſuppoſing that the whole of the menſtrual blood, which contaminates the child, is not thoroughly depurated and expelled by the firſt attack. Even Boerhaave ſeems to have believed, that the *diſtinct* ſmall-pox did not invariably ſecure the individual from a ſubſequent attack of the *confluent* form; though the latter effectually prevented a recurrence. (See his Praxis Medica, § 1381.) This, however, is not conſiſtent with fact: for ſome of the moſt formidable and even fatal attacks of *ſecond* ſmall-pox have occurred in perſons previouſly much pitted and diſfigured by the diſeaſe. It will not be neceſſary to enter, in this place, into a very minute detail of the caſes of ſecondary ſmall-pox: it will be ſufficient to ſtate the fact, and to refer to ſome of the authorities on the ſubject of recent date, ſince the diſtinctions between chicken-pox, and the modifications of ſmall-pox, have been fully eſtabliſhed. The celebrated Dr. De Haen has related ſeveral very clear inſtances of ſecond ſmall-pox, which occurred in his own practice. One young man, a ſtudent of law, received the contagion twice within three years; the firſt attack left him pitted, and the ſecond proved fatal. (See his Ratio Medendi, p. ix. ch. 7: alſo his Epiſt. Apolog. Reſponſ. ad B. L. Tralles.) One of the moſt ſtriking caſes of this ſort, is that of Mr. Langford, whoſe countenance was "remarkably pitted and ſeamed" by a former malignant ſmall-pox, "ſo as to attract the notice of all who ſaw him:" yet at the age of fifty, he was attacked again with confluent ſmall-pox, which proved fatal to him, and to another member of his family, five of whom received the infection from him. (See Memoirs of the Medical Society of London, vol. iv.) A caſe of diſtinct recurrence of ſmall-pox is related by Dr. Laird, in the Edinburgh Journal, already referred to; another by Dr. Bateman, in the Medico-Chirurgical Tranſactions, vol. ii. p. 31; and Mr. Ring has collected a great number, to the amount of ſixty or ſeventy, in his Treatiſe on Cow-pox, and in various numbers of the London Medical and Phyſical Journal, eſpecially in volumes 12, 14, and 15. We may add, that the recurrence of meaſles, in ſeveral caſes, has been lately authenticated, by the firſt medical authority now living, (we mean by Dr. Baillie,) in a paper publiſhed in the third volume of the Tranſactions of a Society for the Improvement of Medical and Chirurgical Knowledge. The ſcarlet fever appears to be alſo ſubject to the ſame anomalies occaſionally. The exceptions, however, are rare in all theſe eruptive fevers, and the general rule will ſtill hold good. Yet the conſiderations of theſe exceptions ſhould remove our ſurpriſe, that the cow-pox ſhould not invariably ſecure the conſtitution from a ſubſequent ſeizure by the ſmall-pox; ſince its influence on the ſyſtem is commonly leſs conſiderable, than that of the mildeſt diſtinct ſmall-pox. We believe, however, that the ſmall-pox, which, under the exceptions, has been occaſionally ſeen to follow the cow-pox, has *always* been much mitigated by the prior operation of the vaccine *virus*, both in the violence and duration of the ſymptoms, and that it has never, in theſe caſes, terminated fatally.

It appears, from the preceding hiſtory of the ſymptoms, that the ſafety and danger of the ſmall-pox depends almoſt entirely upon the ſmaller or larger number of the puſtules: it becomes very important, therefore, both with a view to the prevention and to the treatment of the diſeaſe, to inveſtigate the origin of this difference in the eruption, and in the ſymptoms which accompany it.

From the difference in the appearance, conſiſtence, colour, &c. of the matter produced, as well as in the number and form of the puſtules, and from the various degrees of fever, and other ſymptoms, which accompany the different ſpecies of ſmall-pox, it might be readily ſuſpected, that the contagion itſelf was different. Experience, however, has completely refuted this ſuppoſition: for there are innumerable inſtances of the contagion, ariſing from a perſon affected with the mild and diſtinct ſmall-pox, producing the confluent kind in others; and, on the other hand, it is extremely common to ſee the diſtinct kind produced by expoſure to the contagion ariſing from a perſon affected with the worſt confluent ſmall-pox. The practice of inoculation has ſtill farther demonſtrated this fact. For the ſame matter was not unfrequently obſerved to produce in one perſon the diſtinct, and in another the confluent ſmall-pox. And in order that no time ſhould be unneceſſarily loſt, where perſons have been in the moſt imminent danger from complete expoſure to the contagion, inoculation has been immediately performed from a confluent ſubject; yet the ſubſequent diſeaſe has been diſtinct and mild. We remember to have heard Dr. Gregory, the able profeſſor of the practice of phyſic at Edinburgh, aſſert, in his lectures, that he had once taken matter from the confluent ſmall-pox of a dying child, with which he inoculated two of its brothers: they had both a very mild diſeaſe: one of them, however, had previouſly taken the caſual infection, for he ſickened in three days from the time of inoculation. Indeed we could ſtate other facts, from the ſame authority, to prove that matter, taken from the puſtules of the dead body, has produced even the mildeſt form of ſmall-pox. It is manifeſt, therefore, notwithſtanding the prejudices of mankind, that the nature of the original contagion has no influence in modifying the diſeaſe which it inflicts: and we muſt infer, that the various forms which the diſeaſe aſſumes, originate from ſome particular ſtate of the conſtitution in the individuals whom it thus variouſly handles. And this condition of the conſtitution muſt be the reſult of external cauſes, ſuch as the ſeaſons, and ſtate of the atmoſphere; or of internal and perſonal cauſes, ſuch as plethora, obeſity, irritability, or the contrary, depending on original conformation, or upon indulgence, intemperance, affections of the mind, and ſo forth. It is not the contagion of ſmall-pox alone, which is variouſly modified in this way by the exiſting condition of the conſtitution; almoſt all external agents are ſo modified. The ſcratch of a thorn will not be felt for an hour by one perſon; while in another it will inflame and form an abſceſs, even excite the abſorbents, and produce a bubo and fever; or it may run on to gangrene, and occaſion death. In like manner, if ſeveral people are expoſed to cold, by falling into water, for inſtance, and remaining wet: the effects will be very different individually. Many will eſcape without inconvenience; ſome with a common coryza or ſore-throat; another will be confined to bed for weeks with an univerſal rheumatiſm; another will be attacked with pleuriſy, or a ſpitting of blood, or an inflammation in the bowels. It is preciſely the ſame with the varieties of ſmall-pox: they are not the reſult of a difference in the cauſe, but ſolely of a difference in the ſtate of individual conſtitutions.

The effect of different ſeaſons upon the human conſtitution does not admit of very ſatisfactory explanation. Sydenham and Boerhaave, both able obſervers of nature, remarked, that the regular and diſtinct ſmall-pox uſually appears about the vernal equinox, when it is epidemic, increaſing through the ſummer, and attaining its height and ſeverity in the autumn, and commonly diſappearing with the approach of the winter's cold. They both alſo obſerved, that if it commences early, as in January or February, (and Boerhaave adds, more particularly if it has been abſent from the place ſix years,) the following ſummer will be diſtinguiſhed by an epidemic of a ſevere and fatal kind, ſparing none who have not previouſly undergone the diſeaſe, and proving extenſively deſtructive.

The internal peculiarities of conſtitution, which modify the operation of morbific cauſes in general, and of the contagion of ſmall-pox in particular, are more obvious and intelligible. Various hypotheſes about the fermentation excited in the blood, and the free exit or depoſition in the ſkin of the contagious matter, thus multiplied by that proceſs, have been formed to explain this point: and even Dr. Cullen has adopted this abſurd humoral notion, and endeavours to point out the circumſtances "which determine more or leſs of the variolous matter to *ſtick in the ſkin*, or to paſs freely through it." (Firſt Lines, § 598.) But theſe notions are inconſiſtent with facts. In the firſt place, there is no evidence that the contagion acts like leaven upon the blood, "and aſſimilates a great part of it to its own nature." (Cullen, loc. cit.) The blood, as far as its properties are cognizable by the ſenſes, poſſeſſes no qualities which are not common to all inflammatory diſeaſes. There does not appear, indeed, to be any thing analogous to fermentation in the proceſs. The pus that is generated is the reſult of the inflammatory action of the veſſels of the ſkin, and is generated in the ſkin only; it is not floating in the maſs of circulating fluids, and detained in the ſkin, as by a ſieve. Whatever, therefore, increaſes the inflammatory action, increaſes the number of puſtules. Thus, parts of the body that are much heated, as by lying upon them, or keeping them in long and cloſe contact, have a greater number of puſtules than others; and parts that are covered with plaſters, eſpecially thoſe of a ſtimulant kind, are always more thickly beſet with puſtules. If we extend this principle to the conſtitution generally, we ſhall find, that thoſe perſons who are by nature, their period of life, their mode of living, previous indiſpoſition, the ſeaſon of the year, or other cauſes of a more irritable and inflammatory habit, will be more liable to ſuffer ſeverely from the influence of ſmall-pox. An intelligent writer has ſtated, from his own obſervation, that perſons of a ſwarthy complexion, of a dry rigid fibre, not much diſpoſed to perſpire, with brown or black hair, which is of a ſtrong texture and in great quantity, are more liable to a ſevere ſmall-pox than thoſe of a fair complexion, with thin, weak, and light hair, and who are moderately fat, but perſpire freely. He remarks, too, that "perſons afflicted with the palſy, ague, dropſy, and rickets, have commonly a favourable ſmall-pox; and thoſe afflicted with the two former frequently recover from both." (Roe on the Small-Pox, p. 57.) But the natural irritability may be much augmented or diminiſhed by various circumſtances, and thus the danger from the attack of ſmall-pox in like manner increaſed or leſſened. Thus, to uſe the words of the ſame author, "if a perſon ſhould live intemperately, uſe violent exerciſe, drink much ſpirituous liquors, or give any occaſion whatſoever to inflammation, before the attack of the ſmall-pox, the diſeaſe will prove more virulent, although the natural habit be good. On the contrary, if a perſon be of an indifferent habit, and an unpromiſing temperament, but live temperately, eat little animal food, and lead a ſober and ſedentary life, before the diſeaſe attacks him, he bids fair for a happy recovery." We may add, that, upon the ſame principle, the adult age, as more robuſt and more connected with full living, is more liable to ſuffer the diſeaſe ſeverely than childhood.

It ſeems, therefore, ſatisfactorily proved, "that an inflammatory ſtate of the whole ſyſtem, and more particularly of the ſkin," is the cauſe of the multiplication of the puſtules, as well as of the other circumſtances, which belong to the confluent ſmall-pox, ſuch as the early eruption, the erythematous raſh, the continuance of the fever, the effuſion of a more ichorous matter, and from thence the peculiar form, hue, incruſtation, &c. of the puſtules. See Cullen, Firſt Lines, § 600.

Different cauſes have been aſſigned for the ſuperior mildneſs of the diſeaſe, when produced by inoculation, over that which occurs in the caſual way. Some have ſuppoſed that this advantage aroſe from having the choice of the matter of infection in the former caſe; and others have imagined that it was owing to the ſmall quantity of matter which was introduced by the lancet. But from what has been ſaid above, it is manifeſt that the choice of the matter is of no importance; and we know not how ſmall a quantity is received when infection is communicated in the caſual way. But it is very obvious, that, by avoiding the cauſes of an inflammatory diatheſis, by leſſening this condition when it exiſts, by ſhunning the concurrence of other diſeaſes with the ſmall-pox, and by chooſing the proper ſeaſon and time of life, we gain many advantages; and probably theſe were the principal advantages which inoculation poſſeſſed.

Seat of the Small-pox.—It has been a ſubject of much diſpute, though eaſily determined by obſervation, whether the puſtules of the ſmall-pox affect the viſcera and other internal parts. The moſt reſpectable teſtimony in favour of their exiſtence internally, is that of Wriſberg, in the New Gottingen Commentaries, vol. lxvi: but ſome others have alſo maintained that they had ſeen the puſtules, upon diſſection, upon the internal organs. There is no doubt, however, that ſuch obſervations have originated in miſtake. For all the diſſections made by recent and more accurate anatomiſts have demonſtrated, that, beyond the extenſion of the cuticle, no variolous puſtules ever ariſe. Cotunnius, an Italian profeſſor of anatomy, diſſected above forty perſons, who died of ſmall-pox, for the expreſs purpoſe of aſcertaining what parts or organs were inveſted with the puſtules. Theſe examinations were conducted with great attention and accuracy, and in the preſence of a number of ſtudents: and the reſult was, that, though the mouth, tongue, palate, and top of the pharynx, were often full of puſtules, and in ſome few caſes the internal membrane of the trachea was inflamed, and exhibited ſome effuſion; yet not the leaſt veſtige of puſtules was found upon any of the internal parts, even in the œſophagus. "Etenim quod ſpectat interiores partes,—certè non viſcus, non membrana, non glandula, non pars demum interior ulla fuit, quæ in tot exemplis apparuerit puſtulata." (Cotun. de Sedibus Variolarum, § xxxix.) The truth is, as we have already obſerved, the puſtules are little *cutaneous* abſceſſes, the reſult of inflammation in the ſkin alone, and not depoſitories of contagious matter diſtilling from the blood.

Diagnoſis.—It is not eaſy, in general, to diſtinguiſh the fever, which is about to uſher in the ſmall-pox, from common ſimple fever, or from ſome other febrile diſeaſes; ſince its early ſymptoms are not materially different from theſe. It may be preſumed to be variolous fever, when the ſmall-pox is a prevailing epidemic, provided the individual has not undergone the diſeaſe; and eſpecially if he may have been in circumſtances which rendered the communication of infection probable, or if his expoſure to it were well aſcertained. On children, the occurrence of a convulſive fit, on the evening of the ſecond, or on the third day, will lead to a ſuſpicion that the ſmall-pox is about to appear. In all caſes, however, this doubt will commonly be cleared up by the fourth day, when the ſmall-pox will have appeared.

It is not eaſy to confound the eruption of ſmall-pox with any other febrile eruption, except the chicken-pox, which, indeed, has not been demonſtrated as a diſtinct diſeaſe more than fifty or ſixty years. It had been called *variolæ ſpuriæ*, *baſtard* ſmall-pox; and even Dr. Heberden, who has the merit of having given the firſt clear deſcription of the chicken-pox, (ſee Medical Tranſactions of the College of Phyſicians, vol. i. p. 433.) ſtill applied the term *variola* to it; calling it *variolæ puſillæ*. See his Commentarii de Morbis, cap. 96.

The eruption of ſmall-pox is ſlower and of longer duration than that of chicken-pox, the latter being commonly completed in three days, and being covered with ſlight brown ſcabs on the fifth day, at which time the ſmall-pox is at the height of ſuppuration. The inflammation round the chicken-pox is very ſmall, and the contents of them do not ſeem to be owing to ſuppuration, as in ſmall-pox, but rather to what is extravaſated immediately under the cuticle by the ſerous veſicles of the ſkin, as in a common bliſter; whence this fluid appears in a veſicle on the ſecond day, and, upon the cuticle being broken, is preſently ſucceeded by a ſlight ſcab. On the third and fourth days, the ſhrivelled or wrinkled ſtate of the veſicles which remain entire, and the radiating furrows of others, the ruptured tops of which have been cloſed by a ſlight incruſtation, fully characteriſe the chicken-pox, and diſtinguiſh its eruption from the firm and durable puſtules of ſmall-pox. Another circumſtance is alſo to be added to the diagnoſis of theſe two diſeaſes. If the whole eruption of chicken-pox on the face, breaſt, and limbs, be inſpected on the fifth or ſixth day, every gradation of the progreſs of the veſicles will appear at the ſame time, which cannot take place in the ſlow and regulated progreſs of the ſmall-pox. (See Willan on Vaccine Inoculation, p. 95.) We have already noticed the difference in the ſenſation excited by touching the early eruption of the two diſeaſes with the point of the finger, pointed out by the laſt-named author.

Since the introduction of the practice of vaccination, which may be deemed one of the greateſt benefits ever conferred upon mankind by any individual, the diagnoſis between ſmall-pox and chicken-pox has, however, been rendered a little more difficult. For in ſeveral caſes in which the ſmall-pox has occurred in perſons who had undergone the cow-pox (and we have ſeen that even ſmall-pox and meaſles are not always ſecurities againſt themſelves), a mitigated and modified ſmall-pox has commonly enſued, of a veſicular character, or of a ſmall horny appearance, which has not gone through the uſual ſtages; but, inſtead of proceeding to full ſuppuration, has begun to ſubſide and dry away on the ſixth day from the commencement of the eruption. It requires conſiderable attention, therefore, to diſcriminate between this variety of mitigated ſmall-pox and the chicken-pox; and deciſion cannot always be obtained without the experiment of inoculation with the matter of the puſtules. The impreſſion under the finger, the form, and regular progreſs of the ſmall-pox, may be generally recognized, however, up to the ſixth day, by careful obſervation.

Treatment of Small-pox.—Until the year 1798, when Dr. Jenner immortalized his name by the announcement of his great diſcovery of the properties of the cow-pox, no means of *prevention* could be ſuggeſted to any individual, by which he could avoid or protect himſelf from the ſmall-pox. In all large towns, and eſpecially ſince the introduction of the practice of inoculation, a conſtant collection of contagion ſubſiſted, which operated upon every one who viſited them, even for a ſhort time, from their more inſulated ſituations in the country, if they remained ſuſceptible of the diſeaſe. A preventive, however, is now diſcovered, and every one may be rendered ſecure from the influence of this baneful contagion. (See Cow-pox.) At preſent, however, this valuable preventive is not yet univerſally adopted, and the ſmall-pox has carried off in this metropolis, during the year which has juſt terminated (1815), no leſs than one hundred and twenty-nine perſons. We have ſtill, therefore, occaſion to ſtudy the beſt mode of treating the diſeaſe, under the different forms which it aſſumes, when it occurs in the caſual way.

From a view of the hiſtory of the diſeaſe, as above detailed, it appears very evident, that the danger and violence of the ſymptoms are nearly in proportion to the quantity of the eruption; which is again much connected with the degree of fever that accompanies and precedes it. The firſt indication, therefore, is, to moderate the eruptive fever.

In the caſe of inoculated ſmall-pox, this proceſs may be commenced in the interval between the inſertion of the matter and the beginning of the diſorder, that is, ſeveral days previous to the origin of the fever; when, by a light and cooling diet, and by the uſe of laxative medicines, if the habit be full, the body may be brought into a leſs inflammatory ſtate; and thus rendered leſs ſuſceptible of violent inflammatory diſeaſe. But in the caſual ſmall-pox, we have commonly no warning of the malady, until the eruptive fever actually commences; nor, when it has already begun, can we be certain, from any peculiar ſymptoms, that it is any thing but an ordinary fever; unleſs it occurs in perſons who, not having previouſly undergone the diſeaſe, have been notoriouſly expoſed to the infection. It is fortunate, however, that our inability to diſtinguiſh the fever which is about to uſher in the ſmall-pox from common inflammatory fever, is of no moment; ſince the ſame remedies are the moſt appropriate in both caſes. The older practitioners, indeed, miſled by their humoral hypotheſes, about a fermentation in the blood, a ſtruggle of the conſtitution to rid itſelf of the ſcum and dregs that were ſeparated, and a ſalutary effort to diſcharge them by the ſkin, which was ſuppoſed to be manifeſt in the puſtules, unfortunately took an oppoſite view of the ſubject. They thought it neceſſary to aſſiſt and encourage the fever, and very dangerous to repreſs it; and therefore they excluded the cool air, kept the patient in a hot bed, and adminiſtered warm drinks and cordial medicines. The pernicious influence of this practice (which was extended to all febrile complaints) was firſt detected by the ſagacity of our great countryman, Sydenham, in ſpite of the hypothetical doctrines, in which he had himſelf been educated; and his prophecy, that, after his death, his opinion and practice would prevail, has been amply verified. In fact it is now univerſally admitted, that the more the previous fever is moderated, the more all the enſuing ſymptoms will be mitigated. According to the degree of violence with which the fever commences, the activity of the meaſures for moderating it will be various. If the ſymptoms are not ſevere, the patient may be recommended not to keep his bed, but to remain, according to the advice of Sydenham, in a cool apartment, having the benefit of cool air; and at the ſame time to diſcard animal food, and adopt that of a cooling nature, vegetable decoctions, acidulous fruits, and diluent drinks, ſuch as plain cold water, lemonade, whey, &c. All his drinks ſhould be given cold; and the bowels ſhould be freely opened by ſome cooling purgative, as by the neutral ſalts, with a little calomel. If theſe meaſures are adequate to keep down the fever, and if, at the ſame time, the eruption appears early, and in ſmall numbers, the ſafety of the patient may be conſidered as aſcertained; and no farther treatment, except a continuance of the antiphlogiſtic ſyſtem, is neceſſary. The practice of continuing to give purgatives as the eruption declines, appears to be altogether unneceſſary, and may in ſome caſes be hurtful; and it ſeems to be continued rather in compliance with the exploded hypotheſis of ſeparating the contagious matter from the blood, than from any rational inference of experience.

Where the fever comes on, however, with great violence, manifeſting early its character, by a quick, hard pulſe, intenſe heat, and thirſt, a fluſhed countenance, inflamed eyes, ſevere head-ache, a quick and oppreſſed reſpiration, with delirium, eſpecially in adult perſons, and in thoſe of vigorous or plethoric habits, very active meaſures ſhould be immediately adopted. In perſons of the latter deſcription, the firſt object would be to let ſome blood, the quantity of which muſt be determined by a conſideration of the patient's age, conſtitution, and habits of life, and of the violence of the ſymptoms. At the ſame time, although he cannot obey Sydenham's injunction of ſitting up, the cooling plan muſt be adopted to the fulleſt extent in reſpect to his apartment, which ſhould be freely ventilated by the admiſſion of the external air, through open windows and doors, and to his bed, which ſhould be a mattraſs, and as lightly covered as the ſeaſon and his feelings will permit. If the ſkin is intenſely hot and dry, much benefit will be obtained, in the moſt expeditious manner, by ſponging the ſurface occaſionally with cold water, or even by the uſe of the cold affuſion. We have known ſeveral inſtances, in which this fever, not being ſuſpected to be the variolous fever, was treated by the cold affuſion, with the moſt decided alleviation of the fever, and of the ſubſequent eruption. The benefits of this practice in ſcarlet fever, even during the extenſion of the eruption over the whole ſkin, are now generally acknowledged by all phyſicians who have witneſſed the ſalutary and rapid change which it produces, both in the feelings and in the malady of the patient; being, in fact, the moſt efficacious phyſical agent, as well as the moſt expeditious and grateful, that the whole art of medicine is poſſeſſed of; and the only expedient fully entitled to the commendation of the ancient empiric, that of curing "citó, tutó, et jucundé." It is, in truth, but the perfection of the cooling ſyſtem recommended by Sydenham; and when united with cool air, cool drinks, and light coverings, it affords the moſt certain means of controlling the inflammatory fever.

An active purgative will alſo contribute to relieve inflammatory action, and ſhould be ſpeedily adminiſtered, and repeated according to circumſtances. Diaphoretics are alſo recommended, and if they are not of a ſtimulating kind, they may be given with advantage: but the moſt effectual mode of inducing perſpiration is by reducing the dry and burning heat of the ſkin, by cool air and waſhing.

If, however, theſe ſalutary meaſures have been omitted, or have proved inadequate to prevent a numerous eruption, eſpecially upon the face; if the puſtules are not diſtinct; and particularly, if, on the fifth day, the fever does not ſuffer a conſiderable remiſſion; the diſeaſe will ſtill require a great deal of attention. It will ſtill be neceſſary to avoid heat and a heating regimen, and to continue to admit the free acceſs of cool air, although the more active applications of cold, by ſponging or affuſion with water, need not be continued. The beneficial influence of cool and freſh air, indeed, at all periods of the diſeaſe, is very manifeſt; and in order to impreſs this truth more ſtrongly, it may not be improper to relate a caſe or two, from among many that have been recorded, to ſhew the extent of that influence, even in the later ſtages. Sir George Baker, in his "Enquiry into the Merits of a Method for inoculating the Small-pox, &c." obſerves, "The hiſtory recorded by Sydenham, of a young man at Briſtol, who owed his recovery to his being laid out on a table, as if dead, is ſufficiently known. To this hiſtory there is a great reſemblance in a caſe which is mentioned by Dr. Kirkpatrick, as having happened in Carolina. Mr. Benjamin Marych had a violent natural confluent ſmall-pox in the hot weather. His attendants thought him dead; upon which the ſaſhes were immediately ſet open, and a freſh quantity of air, or poſſibly a wind, ruſhing in, produced a freſh reſpiration and motion in the perſon who was thought dead. When this was obſerved, they went to put them down again. The patient who ſaw it, and was ſpeechleſs, but ſenſible of the alteration and benefit, beckoned with his hand to prevent them; and by degrees entirely recovered." Another caſe of the ſame kind is related by a gentleman of great veracity and experience. "In the year 1736, a man who lived as ſervant with Mrs. Broderep, one of the daughters of archbiſhop Wake, in Great Ormond-ſtreet, had the confluent ſmall-pox; and on the evening of the fifteenth or ſixteenth day, his life was entirely deſpaired of. On the next morning, when I went rather to enquire after him than to viſit him, the nurſe's report was, that he had grown worſe and worſe till two or three o'clock in the morning, at which time he ceaſed to breathe, became inſenſible and motionleſs, and appeared to be abſolutely dead. About five or ſix o'clock, the body was removed and placed on a large table, near an open window, with no covering except only a ſhirt. No ſign of life appeared, but the body continued hotter than is common after death. This heat, however, the nurſe attributed to the weather. In this ſtate he had remained about an hour, when the nurſe heard a ſort of ſigh, or faint breathing; and it was obſerved that he had moved his arm acroſs his ſtomach. Being raiſed up with ſome difficulty, he took a ſpoonful of a cordial medicine, ordered for him on the preceding day; and as ſoon as he was able to ſpeak, he ſaid the cold air was very refreſhing. Being carried back to the bed, he fell into a ſweat, and ſlept three or four hours. About this time I ſaw him. His pulſe was now equal and ſtrong; his reſpiration better than it had been for ſeveral days before; and his ſenſes perfect. The door and windows were left open, and in a few days the man was quite out of danger." (See ſir G. Baker's Eſſay, above quoted; and Dr. Walker's work on Small-pox.) Theſe facts require no comment. They demonſtrate the beneficial influence of cool air at all periods of the diſeaſe. It is, however, particularly beneficial at the period of which we are now ſpeaking, when a thick eruption is coming out, and the fever does not remit. At this time the expoſure to cool air, with the other antiphlogiſtic meaſures, will often greatly leſſen the indiſtinct crowd of puſtules that is ſpreading over the face, and occaſion a few regular ones to ariſe, the head will loſe its confuſion, and the breathing become leſs oppreſſed,

At this period of the diſeaſe, too, under the ſame circumſtances, it may be neceſſary, in adult and plethoric ſubjects, to take away ſome blood. This, however, ſeldom requires to be repeated. But a cooling purgative ſhould be adminiſtered and repeated, or aided by a frequent repetition of laxative glyſters; and the free uſe of diluent drinks ſhould be permitted.

Moſt writers from Sydenham downwards, and Boerhaave and Cullen among the reſt, have recommended the adminiſtration of an *opiate*, every night, under this febrile condition, that continues after the eruption of confluent ſmall-pox has appeared. Sydenham, however, only gave it to patients whoſe age exceeded fourteen years: but Boerhaave and Cullen ſpecify the fifth day as the time for the commencement of opiates, and mention no exception. It does not appear, that modern experience has confirmed the views of theſe great phyſicians: indeed, when Sydenham ſpeaks of uſing opium or bleeding to effect the ſame purpoſe, we are unable to conjecture what powers he aſcribed to the former remedy. "Jam non aliis auxiliis (cum in propinquo mors ſit) ægro ſubveniri poſſe autumo, quam vel *narcotica* affatim exhibendo, vel *ſanguinem* liberaliter *extrahendo*," &c. (Obſ. Medicæ, ſect. iii. cap. 2.) Dr. Walker has juſtly animadverted on this practice, which, however it may alleviate reſtleſsneſs and pain, in ſlight caſes, unaccompanied by acute fever, is well known to accelerate the circulation, to harden the pulſe, to augment the heat and thirſt, to increaſe delirium, to diminiſh the ſecretions; in a word, to aggravate all the ſymptoms of inflammatory fever, while it fails to produce the anticipated reſt, or rather baniſhes it more effectually. Such we know to be the effects of an opiate in all the *phlegmaſiæ*, or acute and viſceral inflammation; as well as in the active ſtages of common fever; and we know no circumſtance in the early ſtage of ſmall-pox, which conſtitutes any exception to this fact, or which modifies the ordinary operation of the medicine. A ſteady purſuit of the antiphlogiſtic plan is a much more effectual ſoother of the irritation which the patient ſuffers. Sydenham and other writers urge the impropriety of interfering with the ptyaliſm, that uſually occurs in confluent ſmall-pox ſoon after the eruption is out, and deem the ſuppreſſion of it highly dangerous. Yet the tendency of opium to leſſen the ſecretions is well underſtood: but the principal injury to be apprehended from it is the excitement which it produces. In the later periods of the diſeaſe, however, when the febrile excitement is low, and much irritation is kept up by the hardening cruſts, the moderate uſe of opiates is to be recommended.

The antiphlogiſtic practice, above recommended, ſhould be continued during the progreſs of the eruption to maturation, unleſs ſome particular ſymptoms of failure of the *vis vitæ* ſhould enſue. For in every caſe of ſmall-pox, where the eruption of puſtules is numerous, although ſome abatement of the fever is diſcernible upon the complete eruption of the ſpots, yet there is ſeldom a perfect remiſſion of the fever, the pulſe rarely deſcending below 90 or 100 in the minute. The *ſecondary fever*, therefore, which occurs about the eleventh day, upon the complete ſuppuration of the puſtules, or at leaſt when theſe are perfectly full and ſtretched to their utmoſt extent, whatever may be the nature of the fluid which they contain, is rather an augmentation of the exiſting fever than a new fever. The origin of this fever, in the opinion of Sydenham and moſt of the writers who followed him, was the re-abſorption of the virus of the puſtules into the blood, as well as the retention of the ordinary perſpirable matter, which could not paſs off by the ſkin. Whence they recommended blood-letting, which, they believed, was the moſt effectual mode of depurating the blood thus contaminated, as the means of cure for this fever. But not only was their theory very bad, (for ſurely drawing a few ounces of blood from the circulating maſs could have no effect in removing the corruption from that which remained in the veſſels,) but their practice was often injurious, by reducing the ſtrength of the patient, at a time when the powers of life were about to fail, and require all poſſible ſupport. Dr. Freind had the merit of pointing out the ſuperior advantages of gentle purgatives in mitigating the ſecondary fever. The bowels ſhould be gently but ſteadily opened, in all caſes, at the commencement of this fever, provided no diarrhœa has occurred. According to the ſtate of the pulſe, and the appearance of the matter in the eruptions, the ſtrength of the patient, and other ſymptoms, more or leſs of a cordial plan of treatment muſt, however, be combined with the laxatives. Light liquid nouriſhment, with a little wine and water as drink, ſhould be frequently adminiſtered; and a decoction or infuſion of cinchona, with the mineral acids and a ſlight aromatic, will be given with advantage. If the diſeaſe put on a more malignant character, with petechiæ and hæmorrhages, the cordial treatment muſt be increaſed both in quantity and ſtrength; but the ſtate of the bowels muſt ſtill be regulated. Under this cordial plan, the petechiæ will ſometimes diſappear; the empty veſicles will become filled with matter; and the ichorous fluid of others be changed into white thick pus; the other ſymptoms of courſe improving in a ſimilar degree.

Such is the general plan of cure which experience has ſanctioned in the ſmall-pox. But in particular caſes particular ſymptoms are very urgent, modifying the character of the diſeaſe, and requiring ſome modification of the method of treatment.

Little can be done to controul effectually the *ſalivation*, when that diſcharge is exceſſive, nor to reſtore it when it ſuddenly ſubſides. In the former caſe, and when the patient is in danger of ſuffocation from the viſcidity of the ſaliva, and the difficulty of diſcharging it, the mouth and throat may be frequently waſhed or ſyringed with a gargle containing oxymel, or ſome of the mineral acids. And, as the ſaliva often begins to thicken on the eleventh day, Sydenham recommended a bliſter (which has been often found beneficial) to be applied between the ſhoulders, on the evening of the tenth day, by way of prevention. The *diarrhœa*, when it occurs ſpontaneouſly, being by all writers deemed rather ſalutary than injurious, ſhould not be interfered with. The *ſwelling of the head, face,* and *fauces*, when it is exceſſive, is highly dangerous, and commonly accompanied by viſcidity or ſuppreſſion of the ſalivary diſcharge. The ſteady purſuit of the antiphlogiſtic ſyſtem is the beſt preventive of this danger, and the free diſcharge occaſioned by laxatives affords the beſt means of drawing off the determination of the fluids to thoſe parts.

The *head-ache* and *delirium*, when violent and accompanied with intolerance of light, and other phrenitic ſymptoms, mark the violence of the fever from the beginning, as well as the too great fulneſs of the veſſels of the head, and therefore demand, not only the moſt rigid purſuit of the antiphlogiſtic plan, the free admiſſion of cool air, and active purgation, but alſo the particular application of cold to the head; the detraction of blood by leeches or cupping from the temples or nucha; or even general blood-letting. The pediluvium is ſometimes recommended for the purpoſe of relieving the head on the principle of revulſion; but we have more than once expreſſed our doubts both of the truth of the hypotheſis and of the advantages of the practice. When the determination to the head is ſuch as to produce actual *coma*, during the eruptive fever, a moſt dangerous ſmall-pox is to be apprehended; and the cooling evacuating meaſures juſt recommended ſhould be carried as far as diſcretion and experience will juſtify, and a bliſter ſhould be applied to the neck.

Inflammation of the throat is a common attendant on all the varieties of ſmall-pox, even the mildeſt; but in the latter it is ſlight, and eaſily relieved by any acidulous and mucilaginous gargle, ſuch as an infuſion of figs, acidulated with lemon-juice, apple-tea, or lemonade. But the angina, which accompanies the worſt kinds of ſmall-pox, is more acute and obſtinate, and from extending to the *glottis*, it frequently produces a conſiderable degree of hoarſeneſs. It is alſo increaſed by the general inflammation and tumefaction of the contiguous parts, and continues till theſe ſubſide. This ſymptom is moderated by the antiphlogiſtic regimen, by blood-letting in inflammatory habits, and eſpecially by the early courſe of laxatives, which contribute to prevent and diminiſh all the inflammatory ſymptoms.

Difficulty of breathing is an alarming ſymptom in ſmall-pox, and ſeldom occurs except in the worſt kinds, and in the laſt ſtage of the diſeaſe, eſpecially when it is left to nature, or improperly treated in the preceding periods. In caſes where the cheſt is narrow and contracted, or there is a conſtitutional prediſpoſition to diſeaſe in the lungs, this ſymptom may occur at an earlier ſtage. Its appearance implies a threatening or preſent inflammation or peripneumony, and requires more than any other ſymptom the free uſe of blood-letting, as well as the exhibition of cooling purgatives, and the whole antiphlogiſtic plan.

Some degree of *ſuppreſſion of urine* not unfrequently takes place in ſevere caſes of ſmall-pox, eſpecially from bad management in the beginning of the diſeaſe; it is commonly attended by coſtiveneſs, and is moſt effectually relieved by promoting the inteſtinal diſcharge, eſpecially by laxative glyſters. An immediate evacuation is ſometimes produced, as Sydenham remarked, by taking the patient out of bed, and ſupporting him expoſed to the cool air in his ſhirt, but ſtill more effectually by placing his feet on a cold floor or hearth, which commonly induces a ſpeedy diſpoſition in the bladder to contract and expel its contents.

It only remains that we allude to the means which have been deviſed to prevent the deformity which is too often produced by ſmall-pox by the *pits* which it leaves behind. As the pits have been aſcribed to the retention of the acrid matter under the cuticle, and the conſequent corroſion of the true ſkin; ſo it has been propoſed to open the puſtules, in order to allow the ichor to be diſcharged. (See Van Swieten, Comment. ad Aph. 1402.) This plan, however, has not proved ſucceſsful, and the theory is probably erroneous. Others have propoſed the covering of the face in the laſt ſtage of the diſeaſe, to ſecure it from the air, and the uſe of fomentations at the ſame time with warm milk, and inunctions with unſalted butter, hog's-lard, or oil. Dr. Walker, in his valuable work already often quoted, adopts a ſimilar method, but at a ſomewhat earlier period. He maintains that the pits do not originate either from the acrimony of the contained matter, from ulceration, or from any loſs of ſubſtance of the ſkin; but that they are, in fact, merely *impreſſions*, made in the tender ſkin by the preſſure of the hardened and deſiccated puſtules, or ſcabs, as a ſeal impreſſes melted wax. This, however, may be juſtly queſtioned; for the ſkin, tender as it may be, is probably not capable of receiving any impreſſions ſo permanent, and muſt be partially ulcerated, and loſe a portion of its ſubſtance by ſloughing, under each hardening puſtule. It is true, however, that the face is chiefly liable to be pitted, from the greater drying and hardening of the crowd of puſtules which cover it, and that this may probably be owing to its greater expoſure to the air. Whence the early prevention of ſuch expoſure, and the ſoftening of the drying puſtules, certainly promiſe the beſt ſecurity againſt ſevere pitting. About the tenth day of the diſeaſe, ſometimes ſooner, according to the kind of ſmall-pox, the apices of the puſtules on the face change colour, feel rough, and begin to harden, eſpecially about the mouth and chin, which are more chafed by the bed-clothes. At this time, therefore, Dr. Walker ſpread over the face a maſk, of fine old cambric, thinly ſmeared with a mild liniment, compoſed of oil, ſpermaceti, and a little wax. This maſk he renewed three or four times in twenty-four hours, and ſometimes oftener, eſpecially when urged by the patient, who generally felt an agreeable and refreſhing coolneſs for ſome time after each application. On removing the maſk, the face was gently touched with a ſoft cambric handkerchief, and expoſed to the air for as ſhort a time as poſſible. By this expedient, he affirms, the variolous matter is ſeen through the tranſparent maſk to be preſerved in a ſtate of fluidity as long as it remains in that ſtate on other parts of the body, or until it is gradually diſcharged by oozing out. The maſk is to be continued till the puſtules are perfectly emptied, which happens in the courſe of ten, twelve, or fifteen days, and in ſome kinds of ſmall-pox in a longer time. Dr.

Walker affirms, "in the application of this theory of pits, in the varieties of ſmall-pox that have come under my care, I have conſtantly found the above mode of treatment to anſwer my higheſt expectation, not only in preventing pits in the worſt caſes of this diſeaſe; but muſt obſerve an agreeable and unexpected effect, which I have conſtantly found to accompany it, namely, a preſervation of the natural features. Many have experienced ſuch an alteration in the countenances of their friends and children, from the effects of this diſeaſe, that they could ſcarcely know them again. This diſagreeable effect has been completely prevented, in every caſe that I have met with, by the method above directed." (Loc. cit. p. 398.) He adds, however, that the ſucceſs of this application ſtands connected with the antiphlogiſtic and evacuant plan of treatment, which he judiciouſly recommends, and which accords with that which we have above detailed.

In ſome conſtitutions, as we have already ſtated, the diſturbance excited by the ſmall-pox is ſuch as to leave the patients in a ſtate of great prediſpoſition to diſeaſe, eſpecially in the glandular ſyſtem, and all the forms of ſcrofula are occaſionally ſeen to follow its ravages, as well as ſome other cachectic conditions. One of the moſt formidable conſequences, however, of confluent ſmall-pox is the loſs of ſight, which it frequently occaſions, and which is ſo common indeed in this country, that a large majority of the blind who are ſeen in the ſtreets owe their loſs of viſion to the ſmall-pox. This, however, is rather the reſult of the extenſion of inflammation to the eyes during the attack of the confluent ſmall-pox, than a *ſequela* of the diſeaſe, and therefore is to be prevented rather by the proper practice during the eruption above detailed, than by any ſubſequent treatment. With a view to anticipate the morbid conſequences, upon the ſuppoſition that they ariſe from the remains or dregs of the contagion ſtill contaminating the blood, it is uſual to adminiſter a ſucceſſion of purgatives, to clear the circulating fluids of theſe impurities. We do not profeſs to underſtand how, by exciting the actions of the exhalents of the inteſtines, we can draw out of the blood juſt the impure portion, leaving the reſt unpolluted; and conſider both the contamination and the purification of the blood as equally gratuitous ſuppoſitions. Where the patient comes out of the diſeaſe with every appearance of returning health, we do not perceive the neceſſity of reſorting to theſe hypothetical cleanſers, which, if violent, may do harm, and can only be productive of benefit by aſſiſting the digeſtion and propulſion of the aliments in a gentle way. And where there are appearances of a bad habit of body, or a ſlow convaleſcence, more advantages are probably to be obtained by a proper attention to diet and regimen, with a judicious courſe of alterative and gently tonic medicine, than by the repetition of cathartics. A diet of milk and vegetables, or very light animal fluids, with appropriate exerciſe, change of air, the tepid bath, and other means which medicine affords of regulating the functions and gradually reſtoring the ſtrength, ſhould be purſued with diligence, eſpecially where there is a diſpoſition to hectic fever connected with the debility. Some forms of ſcrofula and cachexia, however, which are more local and unaccompanied by fever, require a more nutritious and cordial plan of treatment, to be determined by the age and other circumſtances of the patient.

An able and ingenious project was propoſed ſeveral years ago by Dr. Haygarth for the extermination of ſmall-pox in Great Britain, turning upon the principle of a general inoculation. (See his Sketch of a Plan, &c. in 2 vols. 1793.) It is unneceſſary, however, now to enter into any diſcuſſion reſpecting the efficacy or importance of ſuch a plan; ſince the diſcovery of the influence of the cow-pox, by the immortal JENNER, has afforded us an antidote, which requires only a general adoption to ſuperſede altogether that fatal and formidable malady, and to preſerve mankind from all the miſeries and evils which it has ſpread over the earth for many centuries paſt. See COW-POX and INOCULATION.

SMALLS, THE, in *Geography*, rocks in the Iriſh ſea, on which a light-houſe is erected for the guidance of ſeamen, about 15 miles S.W. from St. David's Head. N. lat. 51° 44′. W. long. 5° 33′.

SMALRIDGE, GEORGE, in *Biography*, a learned Engliſh prelate, was the ſon of a dyer at Litchfield, in which city he was born in 1663. He was educated at Weſtminſter ſchool, where his fine talents and excellent diſpoſition rendered him a general favourite. In 1682 he was elected to a ſtudent's place in Chriſt's college, Oxford, in which he became in due time a tutor; and his reputation cauſed him, at an early age, to be ſelected, with others, as managers of the controverſy with Obadiah Walker, maſter of the Univerſity college, a convert to popery. In this connection he publiſhed, in 1687, "Animadverſions on the Eight Theſes laid down, and the Inferences deduced from them, in a Diſcourſe entitled 'Church Government,'" &c. About this period he diſtinguiſhed himſelf as a votary of polite literature, of which he gave ſpecimens in the "Muſæ Anglicanæ." He entered into holy orders in 1692, and was appointed miniſter of Tothill-fields chapel, and he alſo obtained a prebend in the cathedral of Litchfield. In 1700 he took the degree of D.D., and frequently acted as deputy to Dr. Jane, regius profeſſor of divinity at Oxford. On the death of Dr. Jane, in 1707, he was ſtrongly recommended by the univerſity for his ſucceſſor, but the Whig intereſt carried it againſt him. Being now a celebrated preacher, he was choſen, in 1708, lecturer of St. Dunſtan's in the Weſt, London, and he was alſo appointed a member of the lower houſe of convocation, and exerted himſelf very much to procure for his friend, Dr. Atterbury, the prolocutor's chair, on which occaſion he pronounced an elegant Latin panegyric on his friend, touching with much feeling and delicacy, as an apologiſt, upon the heat in controverſy imputed to him. Dr. Smalridge, though of the party, avoided the animoſities too prevalent in its diſputes. He held alſo a friendly correſpondence with Dr. Clarke and Whiſton, and was extremely uſeful in moderating the violent proceedings inſtituted by the convocation againſt them. He aſſiſted Whiſton in his tranſlation of the Apoſtolical Conſtitutions. He propoſed a conference with Dr. Clarke on the ſubject of the Trinity, which was held at the ſeat of Mr. Cartwright, at Aynho, in Northamptonſhire, and in which Dr. Smalridge was the advocate of orthodoxy. Theſe connections cauſed him to be ſuſpected of an inclination towards Arianiſm, from which he deemed it neceſſary to vindicate himſelf by a letter to biſhop Trelawny, a ſhort time before his death. In 1711, Dr. Smalridge was made a canon of Chriſtchurch, Oxford, and afterwards dean of Carliſle. When Dr. Atterbury was promoted to the biſhopric of Rocheſter in 1713, his friend ſucceeded him as dean of Chriſtchurch. In the following year he was raiſed to the epiſcopal bench as biſhop of Briſtol, and very ſoon after he was nominated lord-almoner to queen Anne. Upon the acceſſion of George I. he refuſed to ſign the declaration made by ſome of the biſhops, on occaſion of the rebellion in 1715, becauſe it contained a reflection on ſome of the clergy who had joined the jacobites. This ſtep cauſed the poſt of almoner to be taken from him, but he poſſeſſed the eſteem of the princeſs of Wales, afterwards queen Caroline, with whom he continued in favour till his death, which happened in 1719, at Chriſtchurch, where he was interred, and where, ſome years after, a handſome monument was erected to his memory, with an elegant Latin inſcription. He left a widow and two children, who were much befriended by the generoſity of the princeſs of Wales. A collection of 60 of his ſermons was printed after his death, which ſoon came to a ſecond edition. Biog. Brit.

SMALT, the laſt produce of cobalt, a kind of mineral matter, prepared and purified abroad, and brought hither, ſometimes in form of a blue powder, and ſometimes in lumps; chiefly uſed along with ſtarch, to give linens the finer and clearer caſt; and beſt known by the name of powder-blue. See Cobalt.

The preparation of ſmalt, as practiſed in Hermanduria, we find deſcribed in the Philoſophical Tranſactions by Dr. Krieg; who tells us, that the matter it is made of is the mineral ſtone called cobalt, or cadmia mineralis; which being pulverized, and the lighter ſtuff waſhed away, the remainder is laid on a furnace, and by a fire underneath and aſide it, the flames of which are reverberated over it, a matter is ſeparated from it in form of a ſmoke; which, ſticking to the walls, makes what we call arſenic.

When the cobalt has done ſmoking, it is cooled, mixed with pot-aſhes and powder of white flint-ſtones; the mixture is put in pots, and melted for five or ſix hours in a furnace. By this means, the matter is formed into a blue glaſs, which being put in cold water, cracks and grows tender; and is, at length, powdered by an engine, the fineſt part ſeparated by a ſieve, put into a mill, and ground in water into a very fine powder; which, by waſhing, is ſtill farther ſeparated from the coarſer, then dried in warm chambers, barrelled up, and ſent away.

There is not a more precarious proceſs in all metallurgy than the preparation of this fine blue glaſs from cobalt, nor any manufacture in which ſo expert workmen are neceſſary. The carrying the heat to too great a degree, in the roaſting of the cobalt, is a very miſchievous error; and the ſuffering as much of the arſenic as may be to remain in the earth, is greatly to the advantage of the ſmalt; and its colour may be greatly heightened by adding common arſenic to it while it is in fuſion.

It is always neceſſary to make careful and repeated experiments on a new ore, or a kind of cobalt which has not been worked before; by trying it with various degrees of heat in the roaſting, and with different proportions of the flints and pot-aſh in the fuſion. On comparing the ſeveral products of theſe experiments, it will eaſily be ſeen which yields the fineſt colour, and this muſt be always after followed in the great operations.

It is well known, that the beautiful blue glaſs, called ſmalt, is prepared from the fixed earth of cobalt; but experiments have proved, that this earth alone will not acquire that fine colour. Dr. Link tried ſome of it, by keeping it eight hours in the moſt intenſe heat; yet on taking it out, it was only a grey glaſs, excepting that there were a few blue ſpecks in it near the edges of the crucible. Theſe ſpecks make no objection to this doctrine, when properly conſidered; for they were owing, doubtleſs, to the ſame ſubſtance which is found neceſſary to be uſed, in order to procure the blue colour.

Flints are the neceſſary addition to cobalt for the making of the blue glaſs, or ſmalt; and the crucible being made of earth, might eaſily contain ſome particles of ſand. Every piece of ſand is a ſmall ſtone, of the nature of flint; that is, a piece of cryſtal debaſed by earth; and theſe ſmall flints mixing with the glaſs of the cobalt earth, while in fuſion, rendered the ſmall ſpecks, where they were mixed, true ſmalt, while the reſt remained grey and unaltered.

This earth of cobalt evidently contains ſome portion of copper, though ſo ſmall in quantity, that it can never be diſcerned by the common ſigns, and ſo intimately blended with the earth, that it can never be procured ſeparate. The lightneſs of this earth alſo, in which the copper reſides after the ſublimation of the arſenic, is a proof that its quantity muſt be very ſmall; yet that it exiſts there is evident from the colours it affords.

Copper is well known to yield a green colour with acids, and a fine blue with alkalies. Thus, a ſolution of this earth in aqua fortis is of a deep green, and its glaſs, when mixed with the alkali of flints and of pot-aſh, is the deep blue ſmalt: nor is it wonderful, that the vitrified earth of cobalt will never become blue by calcination alone, ſince, if it owes this colour to copper, it cannot be ſuppoſed to ſhew itſelf till called forth by an alkali.

Some cobalt yields ſmalt before roaſting, even better than it would afterwards: this is a peculiar kind of cobalt, but is ſo like the reſt, that it cannot be diſtinguiſhed by the eye; but experiment alone ſhews this property in it.

Though cobalt in general requires roaſting, in order to fit it for yielding the ſmalt, yet its different kinds require ſome more, and ſome leſs roaſting; and the degree can never be judged of by the inſpection of the mineral, but is only known by the experienced artiſt in the proceſs. Hence it is, that expert and intelligent perſons are neceſſary in the ſmalt-works more than in almoſt any other branch of this ſort of buſineſs.

The addition of a ſmall quantity of arſenic, or of the arſenical flowers, during the time that the ſmalt is in fuſion, adds greatly to the beauty of the colour: this is a practice kept ſecret by the workmen of ſome places; and by this means their ſmalt is always rendered better than that of their neighbours.

It is eaſy to ſee from this, that the roaſting of cobalt is the neceſſary beginning of the ſmalt-work, not the diveſting it of its arſenic, which only happens accidentally in that proceſs; and it would be much better if it did not happen, ſince we find the arſenic added afterwards exalts the colour. From hence it is evident, that thoſe cobalts which will make ſmalt without previous roaſting, muſt, as they are found to do, make the very fineſt ſmalt, becauſe their arſenic is yet left in them in great part; and from this alſo appears the neceſſity of having expert workmen for the ſmalt-making; ſince the knowing the degree of fire neceſſary to the ore is a moſt eſſential article, and after the roaſting has been carried to a ſufficient degree, every moment's heat diveſting it of more of its arſenic than was neceſſary, makes the colour of the ſmalt to be made afterwards ſo much the worſe. From this alſo appears the reaſon why the blue, made by precipitation from a ſolution of cobalt, is ſo much ſuperior to the common ſmalt made by fire; becauſe in this the arſenic is all preſerved, whereas, in the common way of preparing it by fire, it is driven off. Philoſ. Tranſ. N° 396. See Azure and Zaffre.

SMAMLEVO, in *Geography*, a town of Ruſſia, in the government of Viatka, on the Kama; 16 miles S. of Sarapul.

SMARA, a name of Kama, the Hindoo cupid. (See Kama.) Smara means the ideal, and in the fanciful mythology of the Eaſt, is the reputed ſon of Maya, or illuſion. See Maya.

SMARAGD, σμαραγδος, a precious ſtone of a green colour, very beautiful and brilliant; called alſo the *emerald*; which ſee. See alſo Gems.

lying upon, the ſegments of the calyx, and about half as long. *Stam.* Filaments ten, awl-ſhaped, ſmooth, the length of the calyx, five of them inſerted into the receptacle, five into the nectaries; anthers incumbent, nearly orbicular, of two cells burſting in front. *Piſt.* Germen ſuperior, ſmall, roundiſh, villous, in five diſtinct lobes; ſtyles five, vertical, erect, cylindrical, ſmooth, ſhorter than the ſtamens; ſtigmas ſmall, obtuſe. *Peric.* Capſules five, ſpreading in the form of a ſtar, obovate, coriaceous, of one cell and two valves. *Seeds* ſeveral, winged.

Eſſ. Ch. Calyx five-cleft. Petals five. Nectary of five orbicular depreſſed lobes, oppoſite to the calyx, alternate with the petals, and bearing five of the ſtamens. Capſules five, ſuperior. Seeds numerous, winged.

1. S. *emarginata.* Chili Soap-bark. (Smegmadermos emarginatus; "Ruiz et Pavon. Syſt. Veg. v. 1. 288. Quillaja ſaponaria; Molin. Chil. ed. Germ. 150.")—Native of woods in Chili, about Puchacay, where it is known by the name of *Quillay.* Our ſpecimen was ſent by the late abbé Cavanilles. The *tree* is ſaid to be twenty ells in height, bearing abundance of leafy branches, which are round, much ſubdivided, knotty, finely downy when young. *Leaves* an inch long, alternate, on ſhort broad ſtalks, broadly elliptical, obtuſe, coriaceous, evergreen, ſmooth, ſhining, veiny, entire in our ſpecimen, though reported to be ſometimes toothed. *Stipulas* minute, awl-ſhaped, membranous, in pairs, deciduous. *Flowers* few together, on axillary or terminal, ſhort, downy ſtalks. *Calyx* expanding more than half an inch, thickly clothed all over with ſhort, denſe, white pubeſcence, as in *Grewia* and *Tilia,* to which we at firſt ſuſpected this genus might be allied; as perhaps is the caſe, though it will not anſwer to Juſſieu's definitions of his *Tiliaceæ,* or indeed any other order. The *petals* are probably white or pink, but of this we have no information. *Capſules* near an inch long, externally downy; their inner coat ſmooth, cracking tranſverſely with age, but we can diſcern nothing like the ſeparate elaſtic tunic of the true *Rutaceæ.*—Nothing but error and inconvenience can reſult from placing this genus in the claſs *Polygamia.*

SMELBURG, in *Geography,* a town of the duchy of Warſaw; 50 miles N. of Gneſna.

SMELL, Odor, with regard to the organ, is an impreſſion made on the noſe by little particles continually exhaling from odorous bodies.

Smell, with regard to the object, is the figure and diſpoſition of odorous effluvia, which, ſticking on the organ, excite the ſenſe of ſmelling.

Smell, with regard to the ſoul, is the perception of the impreſſion of the object on the organ; or the affection in the ſoul reſulting from it.

Smell, like taſte, conſiſts altogether in the arrangement, compoſition, and figure of the parts, as appears from the following experiments of Mr. Boyle.

1. From a mixture of two bodies, each of which is, of itſelf, void of all ſmell, a very urinous ſmell may be drawn: this is done by the grinding of quicklime with ſal ammoniac.

2. By the admixture of common water, which of itſelf is void of ſmell, or inodorous, another inodorous body may be made to emit a very rank ſmell. Thus, camphor diſſolved in oil of vitriol is inodorous, yet mixed with water it immediately exhales a very ſtrong ſmell.

3. Compound bodies may emit ſmells, which have no ſimilitude to the ſmells of the ſimples of which they conſiſt. Thus, oil of turpentine, mixed with a double quantity of oil of vitriol, and diſtilled; after diſtillation, there is no ſmell but of ſulphur; and what is left behind in the retort, being again urged by a more violent fire, yields a ſmell like oil of wax.

4. Several ſmells are only to be drawn forth by motion and agitation. Thus, glaſs, ſtones, &c. which, even when heated, yield no ſmell; yet, when rubbed and agitated in a peculiar manner, emit a ſtrong ſmell: particularly beechwood, in turning, yields a kind of roſy ſmell.

5. A body that has a ſtrong ſmell, by being mixed with an inodorous one, may ceaſe to have any ſmell at all. Thus, if aqua fortis, not well dephlegmated, be poured on ſalt of tartar, till it ceaſe to ferment; the liquor, when evaporated, will yield inodorous cryſtals, much reſembling nitre; yet theſe, when burnt, will yield a moſt noiſome ſmell.

6. From a mixture of two bodies, one of which ſmells extremely ill, and the other not well, a very pleaſant aromatic odour may be gained, *viz.* by a mixture of aqua fortis, or ſpirit of nitre, with an inflammable ſpirit of wine.

7. Spirits of wine, by mixing with an almoſt inodorous body, may gain a very pleaſant aromatic ſmell. Thus, inflammable ſpirits of wine and oil of Dantzic vitriol, mixed in equal portions, then digeſted, and at laſt diſtilled, yield a ſpirit of a very fragrant ſmell.

8. A moſt fragrant body may degenerate into a fetid one, without the admixture of any other body. Thus, if the ſpirit mentioned in the former experiment be kept in a well-cloſed receiver, it will ſoon acquire the rankneſs of garlic.

9. From two bodies, one of which is inodorous, and the other fetid, a very pleaſant ſmell may ariſe, much reſembling muſk, *viz.* by putting pearls into ſpirit of vitriol; for, when diſſolved, they yield a very agreeable ſmell. See Smelling.

Smell is uſed as a name for a peculiar ſort of wine, of which there are two ſpecies; the one ſort is very fragrant, muſcatelline, and aromatic; this is called ſimply the *ſmell-wine:* but the other, which is very rank and offenſive to the noſe, is called by the Germans *ſmell-bruntzer.* Many have been the conjectures about the occaſion of the rank ſmell of this wine.

The ſmell is truly urinous, and is that of a volatile alkali; which not being embodied in, or ſubdued by the acid of the grape in this imperfect fermentation, vents itſelf in this rank manner.

It is evident, that the ſmell is of a volatile nature, for it is often loſt in the drawing of the wine ſeveral times out of one veſſel into another, evaporating during the time of drawing it out.

SMELLIE, William, M.D., in *Biography,* an eminent teacher and practitioner of midwifery, was a native of Scotland. After having ſucceſſively practiſed this art in a ſmall town of that country for a period of nineteen years, he removed to London, and in 1741 was living in Pall-Mall, where Dr. William Hunter reſided with him. This circumſtance implies, that he had already riſen to conſiderable eminence in his line, and he was in fact in high repute as a lecturer, being attended by a numerous concourſe of pupils of both ſexes. This reputation, indeed, he appears to have merited by his talents and aſſiduity; for he was the firſt in propoſing many of the practical improvements, which modern experience has admitted into the practice of midwifery, and by his mechanical ſkill he contributed materially to the improvement of the inſtruments employed to facilitate delivery in difficult caſes, and to the diſuſe of thoſe which were leſs ſafe and convenient; and he eſtabliſhed ſome uſeful rules for their application. He was the firſt writer, who, by accurately determining the ſhape and ſize of the pelvis, and of the head of the fœtus, and comparing their proportions, and the true poſition of the fœtus in utero, pointed out clearly the whole progreſs of the child during parturition: and his opinions were ſubſequently confirmed, eſpecially by Dr. Hunter, from obſervations made after death, where parturition had not been completed. The improvement which he made in the forceps, which has ſince been univerſally adopted, is well known, and he taught the preſent manual mode of uſing them. He aboliſhed many ſuperſtitious notions and erroneous cuſtoms that prevailed in the management of parturient women and of the children; and he had the ſatisfaction to ſee the greater part of his maxims adopted, not only in this iſland, but by many of the moſt reſpectable practitioners in Europe.

In the year 1752, he publiſhed the ſubſtance of his lectures, in the improvement and correction of which he affirms, that he had ſpent ſix years, in one volume 8vo., under the title of "A Treatiſe on Midwifery;" to which, in 1754, he added a ſecond volume of caſes, intended to illuſtrate the precepts laid down in the former. An additional volume of caſes, which he promiſed in his preface, did not appear till about five years after his death, in 1768. The whole formed the moſt complete ſyſtem of the art of midwifery, which had then appeared, and was regarded as the beſt authority: it was, in fact, the reſult of an extenſive experience of forty years, and contained a very comprehenſive view of the various circumſtances that uſually occur, with inſtructions reſpecting the beſt means of obviating them. In 1754, Dr. Smellie likewiſe publiſhed a ſet of anatomical plates, of a large folio ſize, and thirty-ſix in number, which were intended farther to elucidate the doctrines of his lectures. In eleven of theſe he acknowledges the aſſiſtance of the late profeſſor Cowper. Like other ingenious men of original character, Dr. Smellie was aſſailed by ſome critics and opponents, eſpecially by Dr. Burton of York, and by Dr. W. Douglas, with great acrimony; but he ever maintained the character of a man of ingenuity and judgment; he was remarkably candid and modeſt in his demeanour, and upright and diſintereſted in all his concerns. His reputation and ſucceſs were the reſult of his merit alone; for his awkwardneſs of perſon and unpoliſhed manners prevented him from riſing to the higheſt line of practice; but he was much eſteemed by his pupils, and by thoſe who employed him. He ultimately retired to Lanark, where he ſpent the latter years of his life, and died in 1763, at an advanced age. Hutchinſon Med. Biog. Gen. Biog.

SMELLING, the act whereby we perceive ſmells, or by which we become ſenſible of odorous bodies, by means of certain effluvia, which, ſtriking on the olfactory organ, briſkly enough to have their impulſe propagated to the brain, excite a ſenſation of the ſoul.

The principal organs of ſmelling are the noſtrils and the olfactory nerves; the minute ramifications of which latter are diſtributed throughout the whole concave of the former. See NOSE.

Smelling is performed by the odorous effluvia, floating in the air, being drawn into the noſtrils, in inſpiration, and ſtruck with ſuch force againſt the fibrillæ of the olfactory nerves, which the figure of the noſe, and the ſituation of the little bones, render oppoſite thereto, as to ſhake them, and give them a vibratory motion; which action, being communicated hence to the common ſenſory, occaſions an idea of a ſweet, or fetid, or ſour, or an aromatic, or a putrefied object, &c.

The matter in animals, vegetables, foſſils, &c. which chiefly affect the ſenſe of ſmelling, Boerhaave obſerves, is that ſubtile ſubſtance, inherent in the oily parts of them, called *ſpirits:* becauſe, when this is taken away from the moſt fragrant bodies, what remains has ſcarcely any ſmell at all; but this, poured on the moſt inodorous bodies, gives them a fragrancy.

Willis obſerves, that brutes have, generally, the ſenſe of ſmelling in much greater perfection than man; as by this alone, they diſtinguiſh the virtues and qualities of bodies unknown before; hunt out their food at a great diſtance, as hounds and birds of prey; or hid among other ſubſtances, as ducks, &c.

Man, having other means of judging of his food, &c. did not need ſo much ſagacity in his noſe; yet have we inſtances of a very conſiderable degree of it, even in man. In the Hiſtoire des Antilles, we are aſſured, there are Negroes, who, by the ſmelling alone, can diſtinguiſh between the footſteps of a Frenchman and a Negro.

It is found that the laminæ, with which the upper part of the noſtrils is fenced, and which ſerve to receive the divarications of the olfactory nerves, are always longer, and folded up together in greater numbers, as the animal has this ſenſe more accurate: the various windings and turnings of theſe laminæ detain and fetter more of the odoriferous particles.

The ſenſe of ſmelling may be diminiſhed or deſtroyed by diſeaſes; as the moiſture, dryneſs, inflammation or ſuppuration of the olfactory membrane, the compreſſion of the nerves which ſupply it, or ſome fault in the brain itſelf at their origin. A defect, or too great a degree of ſolidity of the ſmall ſpungy bones of the upper jaw, the caverns of the forehead, &c. may likewiſe impair this ſenſe; and it may be alſo injured by a collection of fetid matter in theſe caverns, which is continually exhaling from them, and alſo by immoderate uſe of ſnuff. When the noſe abounds with moiſture, after gentle evacuations, ſuch things as tend to take off irritation, and coagulate the thin ſharp ſerum, may be applied, as the oil of aniſe, mixed with fine flour, camphor diſſolved in oil of almonds, &c. the vapours of amber, frankincenſe, gum-maſtic, and benjamin, may likewiſe be received into the noſe and mouth. For moiſtening the mucus when it is too dry, ſome recommend ſnuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniſeed; or a ſternutatory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water, and filtrated. The ſteam of vinegar upon hot iron, and received up the noſtrils, is alſo of uſe for ſoftening the mucus, removing obſtructions, &c. If there be an ulcer in the noſe, it ought to be dreſſed with ſome emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, twelve grains of corroſive ſublimate may be diſſolved in a pint and a half of brandy, and a table-ſpoonful of it taken twice a-day. The ulcer ought likewiſe to be waſhed with it, and the fumes of cinnabar may be received up the noſtrils.

If there be reaſon to ſuſpect that the nerves, which ſupply the organs of ſmelling, are inert, or want ſtimulating, volatile ſalts, or ſtrong ſnuffs, and other things, which occaſion ſneezing, may be applied to the noſe; the forehead may likewiſe be anointed with balſam of Peru, to which may be added a little oil of amber. See BRAIN, LIFE, and NERVOUS *Syſtem.*

SMELNITZ, or SZOMOLNOK, in *Geography*, a town of Hungary; 14 miles S. of Kapſdorf.

SMELT, *Apua Phalerica*, or *Salmo Eperlanus* of Linnæus, in *Ichthyology*, a fiſh which is claſſed, by the generality of writers, among the truttaceous kinds, and is acknowledged to have a general external reſemblance to the ſalmon. See SALMO *Eperlanus*.

It inhabits the ſeas of the northern parts of Europe, and, Mr. Pennant apprehends, is never found as far ſouth as the Mediterranean.

Theſe fiſh will live almoſt any where, but they are very apt to degenerate. They are common in the rivers of New England, and are as large as with us, often weighing two ounces and a half; but a pailful of theſe being taken from one of their rivers, and put into an adjoining pond, they all degenerated in ſuch a manner, that they were afterwards found ſo ſmall, that the largeſt did not weigh more than five pennyweights. Though thus ſmall, however, they are much valued, and are better taſted than the others. Philoſ. Tranſ. N° 374. p. 232.

They are called ſmelts, becauſe they melt, as it were, or diſſolve between the fingers in handling them; or, as others ſay, on account of their ſcent, *quaſi ſmell it*. The name *ſparling*, by which they are called in Wales and the north of England, is taken from the French *eperlan:* ſmelts are often ſold in the ſtreets of London ſplit and dried, and called *dried ſparlings*.

SMELT *Fiſhing*. See FISHING, *Smelt*.

SMELT, among the fiſhermen in Yorkſhire, and ſome other parts of England, is alſo a name given to the ſalmon, while in its firſt year. See SALMON.

SMELTING, among *Metalliſts*, the melting of a metal from the ore in a ſmelting furnace; in order to ſeparate the metallic parts from the ſulphur and arſenic, and the earthy and ſtrong ſubſtances of all kinds with which they are combined.

Smelting, in propriety, is reſtrained to large works, in which ores from the mines are melted down and ſeparated.

In ſpeaking of works in a leſſer way, we do not ſay ſmelting, but *melting*.

In the more precious metals this is called *refining;* which ſee. And ſmelting is moſt commonly applied to the reduction of iron ores.

The art of ſmelting the ores of all metallic ſubſtances was, probably, at firſt very imperfect; hence the uſe of iron has every where been of a more recent date than that of the other metals, becauſe it requires the application of a much ſtronger fire to ſmelt the ores of iron than thoſe of any other metal. We have no certain accounts when, or by whom, the ſeveral metals were diſcovered. Wallerius ſays, that, as far as he knew, Pliny was the firſt who enumerated the ſix metals; but they were certainly known long before his age, and were mentioned both by Homer and by Moſes, a much more ancient author. (Numb. xxxi. 22.) From this teſtimony we may certainly infer, that all the metals, anciently mentioned, were known, at leaſt in the country of the Midianites, above fourteen hundred and fifty years before the birth of Chriſt, or near nine hundred years after the deluge. Moreover, iron and copper were, without doubt, known before the deluge, and probably all the other metals, which are more eaſily extracted from their ores than the former.

In the time of Abraham, however, gold and ſilver were eſteemed, as they are at preſent, precious metals (Gen. xxiii. 16. Gen. xiii. 2.); and hence it is reaſonable to conclude, that Noah was able to inſtruct his deſcendants in the art of ſmelting metallic ores; this art was afterwards loſt among the various colonies, which quitted the plains of Aſia in ſearch of ſettlements; and as the earth, ſoon after the deluge, and long before it could have been peopled by the poſterity of Noah, muſt have become covered with wood, and in proceſs of time different countries might have been cleared by ſetting the wood on fire, which might flux metallic ores contiguous to the ſurface of the earth, it is not improbable, that the firſt idea of ſmelting ores might have been thus ſuggeſted to many nations. See Creech's Lucretius, vol. ii. p. 572.

We may hence conjecture, that the firſt rude proceſs, by which metals were extracted from their ores, was that of putting a quantity of ore upon a heap of wood, and ſetting the pile on fire, in conformity to the manner, in which ores were ſmelted during the burning of foreſts; but as the force of the fire is greatly diminiſhed by the diſperſion of its flame, and as the air acts more forcibly in exciting fire, when it ruſhes upon it with greater velocity, it is likely that the heap of wood and ore would ſoon be ſurrounded with a wall of ſtone, in which ſufficient openings would be left for the entrance of the air, and thus a kind of furnace would be conſtructed.

The Peruvians, we are told, had diſcovered the art of ſmelting and refining ſilver, either by the ſimple application of fire, or where the ore was more ſtubborn, and impregnated with foreign ſubſtances, by placing it in ſmall ovens or furnaces on high grounds, ſo artificially conſtructed, that the draught of air performed the function of a bellows, a machine with which they were totally unacquainted. This method of ſmelting ores on high grounds, without the aſſiſtance of a bellows, or at leaſt of bellows moved by water, ſeems to have been formerly practiſed in other countries as well as in Peru. There are ſeveral places in Derbyſhire, called *boles* by the inhabitants, where lead has been anciently ſmelted, before the invention of moving bellows by water; theſe boles were always ſituated upon high grounds, and moſtly upon that ſide of a hill which faces the weſt, probably becauſe the wind proceeds moſt frequently from that quarter.

From a pig of lead, dug up in 1766 at one of theſe boles near Matlock, and bearing an inſcription in relievo, from which it appears to have been ſmelted in the age of Adrian; many of the boles in Derbyſhire ſeem to be of high antiquity. However, this method of ſmelting ore by the variable action of the wind, being a very troubleſome and precarious proceſs, has been univerſally diſuſed, and the more regular blaſt of a bellows has been introduced in its ſtead.

The invention of the bellows is attributed by Strabo to Anacharſis, the Scythian; but he was probably the improver of this machine; for Homer, who lived long before his time, deſcribes Vulcan as employing twenty pair of bellows at once in the formation of the ſhield of Achilles. Iliad, lib. xviii. v. 470.

When the art of moving bellows by means of a water-wheel was firſt diſcovered, is uncertain; the ancients ſeem to have been unacquainted with it; but we learn from Agricola (De Re Metal. publiſhed in 1550, pp. 165. 338.) that it was very generally known, at leaſt among the Germans, in his time; for he ſpeaks of it often, without hinting at its being a recent invention. By this advantageous contrivance, however, the moderns have, in many inſtances, worked over again, with conſiderable profit, the heaps of iron and other kinds of ſlag, from which the metal has been but imperfectly extracted, before the moving of the bellows by water was diſcovered.

About fifty years ago, the blaſt, or hearth-furnace, was the only one in uſe for ſmelting lead-ore in Derbyſhire. In this furnace, ore and charcoal, or ore, and what is called *white coal*, which is wood dried but not charred, being placed, in alternate layers, upon a hearth properly conſtructed, the fire is raiſed by the blaſt of a bellows, moved by a water-wheel; the ore is ſoon ſmelted by the violence of the fire, and the lead, as it is produced, trickles down a proper channel, into a place contrived for its reception. Theſe ore-hearths are now very rare; though they are frequently applied to the extracting lead from the ſlag which is produced, either at the ore-hearth, or the cupola furnace, and they are then called *ſlag-hearths*, and the lead thus obtained is called *ſlag-lead;* the fire in a ſlag-hearth is made of the cinder of pit-coal inſtead of charcoal; the furnace called a *cupol*, or *cupola*, and *reverberatory* furnace, and by the Germans a *wind-furnace*, in which ores are ſmelted by the flame of pit-coal, is ſaid to have been invented about the year 1698, by a phyſician named Wright; though Becher may, perhaps, be thought to have a prior claim to its invention, or introduction from Germany. But whoever was the firſt inventor of the cupola, it is now in general uſe, not only in Derbyſhire and other counties for the ſmelting of ores of lead, but both at home and abroad, where it is called the *Engliſh furnace*, for the ſmelting of copper ores. This furnace is ſo contrived, that the ore is melted, not by coming into immediate contact with the fuel, but by the reverberations of the flame upon it. The bottom of the furnace, on which the lead-ore is placed, is ſomewhat concave, ſhelving from the ſides towards the middle; its roof is low and arched, reſembling the roof of a baker's oven: the fire is placed at one end of the furnace, upon an iron grate, to the bottom of which the air has free acceſs; at the other end, oppoſite to the fire-place, is a high perpendicular chimney; the direction of the flame, when all the apertures in the ſides of the furnace are cloſed up, is neceſſarily determined, by the ſtream of air which enters at the grate, towards the chimney, and in tending thither it ſtrikes upon the roof of the furnace, and being reverberated from thence upon the ore ſoon melts it. This furnace does not require the uſe of bellows, and may, therefore, be conſtructed any where. In ſmelting lead-ore, they generally put into the cupola furnace a ton of ore, previouſly beat ſmall and dreſſed, at one time, which quantity they call a *charge;* and they work off three charges of ore in every twenty-four hours. In about ſix hours from the time of charging, the ore becomes as fluid as milk. In order to obtain the lead free from the ſlag which ſwims over it, the ſmelters uſually throw in about a buſhel of lime, which dries up the ſlag, and prevents its running out with the lead. The ſlag, thus thickened, is raked up towards the ſides of the furnace, and the lead guſhes out through a hole in one of the ſides of the furnace, which having been properly ſtopped during the ſmelting of the ore, is opened for this purpoſe into an iron pot, from which it is laded into iron moulds, containing what they call a pig of lead; the pigs, when cold, being ordinarily ſtamped with the maker's name, are ſold under the name of *ore-lead.* After the lead has all flowed out of the furnace, they ſtop up the tap-hole, and drawing down the ſlag and lime into the middle of the furnace, they raiſe the fire, till the mixture of ſlag and lime, which they ſimply term *ſlag*, is rendered very liquid; upon this maſs they throw another quantity of lime, and proceed as before. When the lead thus obtained, amounting generally to twenty or thirty pounds, is let out of the furnace, a new charge of ore is put in and the operation renewed.

In order to ſpare the time and expence of fuel, they have, in ſome furnaces, lately contrived a hole, through which they ſuffer the main part of the liquid ſlag to flow out, before they tap the furnace for the lead; upon the little remaining ſlag they throw a ſmall portion of lime, and draw the mixture out of the furnace without ſmelting it. This kind of furnace they have nicknamed a *maccaroni.*

Dr. Watſon has ſuggeſted ſome improvements in the conſtruction of this furnace, and in the proceſs of ſmelting above deſcribed. He propoſes to ſubſtitute an horizontal chimney in the place of the perpendicular one now in uſe, and that the end fartheſt from the fire ſhould be turned up by a tube of earthen-ware, or otherwiſe; ſo that the ſulphureous acid, ſet at liberty during the burning of the ſulphur, may iſſue out in a direction parallel to the flue of the chimney, and at the diſtance of about one foot and a half above it. Let a number of large globular veſſels be made either of glaſs or lead, each of which muſt have two necks, ſo as to be capable of being inſerted into one another: let theſe veſſels be placed in the flue of the chimney, the neck of the firſt being inſerted into the above-mentioned tube, and the neck of the laſt being left open, for fear of injuring the draught of the furnace. Let each of theſe globular veſſels contain a ſmall quantity of water, in which caſe, he apprehends, that the heat of the flue will raiſe the water into vapour, and that this watery vapour will be the means of condenſing the ſulphureous acid vapour, in ſuch a degree as to render the undertaking profitable. When the ſulphur is all conſumed, the draught of the furnace may be ſuffered to have its ordinary exit at the end of the horizontal chimney, by a very ſlight contrivance of a moveable damper.

The ſame ingenious writer alſo obſerves, that very ſulphureous ore ſhould be roaſted for a long time with a gentle heat. He alſo propoſes to leave as little lead as poſſible in the ſlag; for this purpoſe he ſuggeſts, that it might be uſeful to throw a quantity of charcoal-duſt upon the liquid ſcoria in the cupola furnace, in order that the calcined lead might be converted into lead, by uniting itſelf to the inflammable principle of the charcoal; and that it might be alſo uſeful to flux ſulphureous lead-ores in conjunction with the ſcales or other refuſe pieces of iron, or even with ſome ſorts of iron-ore.

The ſmelter might farther find it worth his while to reduce the ſlag into a powder by a ſtamping mill, or to grind it by any other contrivance, and then he may ſeparate the ſtony part of the ſlag from the metallic, by waſhing the whole in water, inaſmuch as the metallic part is heavier than the other. Watſon's Chem. Eſſ. vol. iii. p. 253, &c.

The other furnaces uſed in ſmelting are ſupplied with large bellows, moved by the arbor of a wheel, which is turned round by a current of water. Theſe have obtained different names, according to ſome difference in their conſtruction. Their greater or leſs height gives occaſion alſo to the diſtinction of *high furnaces* and *middle furnaces.* The high furnaces are of modern invention; they were firſt introduced at Mansfelt in 1727, and are now uſed in almoſt all countries where ores are ſmelted, as in Saxony, Bohemia, Hungary, &c. They contribute, by their great height, being above eighteen feet high, which allows the ore to undergo a roaſting by different degrees of heat before it is melted, to ſimplify and diminiſh the labour. They are chiefly employed for crude fuſions, and particularly for the ſlate copper-ore.

In order to facilitate the extraction of metallic ſubſtances from the ores and minerals containing them, ſome operations, previous to the fuſion or ſmelting of theſe ores and minerals, are generally neceſſary. Theſe operations conſiſt of, 1. The *ſeparation* of the ores and metallic matter from the adhering unmetallic earths and ſtones, by hammers, and other mechanical inſtruments, or by waſhing with water. 2. Their *diviſion* or reduction into ſmaller parts by contuſion and trituration, that by another waſhing with water they may be more perfectly cleanſed from extraneous matters, and rendered fitter for the ſubſequent operations. 3. *Roaſt-*

ing, or *calcination*, the uſes of which operation are to expel the volatile, uſeleſs, or noxious ſubſtances, as water, vitriolic acid, ſulphur, and arſenic; to render the ore more friable and fitter for the ſubſequent contuſion and fuſion; and, laſtly, to calcine and deſtroy the viler metals; for inſtance, the iron copper-ores, by means of the fire, and of the ſulphur and arſenic. Stones, as quartz and flints, containing metallic veins or particles, are frequently made red-hot, and then extinguiſhed in cold water, that they may be rendered ſufficiently friable and pulverable, to allow the ſeparation of the metallic particles.

Roaſting is unneceſſary for native metals; for ſome of the richer gold and ſilver-ores; for ſome lead-ores, the ſulphur of which may be ſeparated during the fuſion; and for many calciform ores, as theſe do not generally contain any ſulphur and arſenic.

In the roaſting of ores, the following attentions muſt be given: 1. To reduce the mineral previouſly into ſmall lumps, that the ſurface may be increaſed; but they muſt not be ſo ſmall, nor placed ſo compactly, as to prevent the paſſage of the air and flame. 2. The larger pieces muſt be placed at the bottom of the pile, where the greateſt heat is. 3. The heat muſt be gradually applied, that the ſulphur may not be melted, which would greatly retard its expulſion; and that the ſpars, fluors, and ſtones, intermixed with the ore, may not crack, fly, and be diſperſed. 4. The ores not thoroughly roaſted by one operation muſt be expoſed to a ſecond. 5. The fire may be increaſed towards the end, that the noxious matters more ſtrongly adhering may be expelled. 6. Fuel which yields much flame, as wood and foſſile coals free from ſulphur, is ſaid to be preferable to charcoal or coaks. Sometimes cold water is thrown on the calcined ore at the end of the operation, while the ore is yet hot, to render it more friable.

No general rule can be given concerning the duration or degree of the fire, theſe being very various according to the difference of the ores. A roaſting during a few hours or days is ſufficient for many ores; while ſome, ſuch as the ore of Rammelſberg, require that it ſhould be continued during ſeveral months.

Schlutter enumerates five methods of roaſting ores. 1. By conſtructing a pile of ores and fuel placed in alternate ſtrata, in the open air, without any furnace. 2. By confining ſuch a pile within walls, but without a roof. 3. By placing the pile under a roof, without lateral walls. 4. By placing the pile in a furnace conſiſting of walls and a roof. 5. By roaſting the ore in a reverberatory furnace, in which it muſt be continually ſtirred with an iron rod.

Several kinds of *fuſions of ores* may be diſtinguiſhed. 1. When a ſulphureous ore is mixed with much earthy matter, from which it cannot be eaſily ſeparated, by mechanical operations, it is frequently melted, in order to diſengage it from theſe earthy matters, and to concentrate its metallic contents. By this fuſion, ſome of the ſulphur is diſſipated, and the ore is reduced to a ſtate intermediate betwixt that of ore and of metal. It is then called a *matt* (lapis ſulphureo-metallicus), and is to be afterwards treated like a pure ore by the ſecond kind of fuſion, which is properly the ſmelting, or extraction of metal by fuſion. 2. By this fuſion or ſmelting, the metal is extracted from the ore previouſly prepared by the above operations, if theſe be neceſſary.

The ores of ſome very fuſible metals, as of biſmuth, may be ſmelted by applying a heat ſufficient only to melt the metals, which are thereby ſeparated from the adhering extraneous matters. This ſeparation of metals by fuſion, without the vitrification of extraneous matters, may be called *eliquation*. Generally, a complete fuſion of the ore and vitrification of the earthy matters are neceſſary for the perfect ſeparation of the contained metals. By this method, metals are obtained from their ores, ſometimes pure, and ſometimes mixed with other metallic ſubſtances, from which they muſt be afterwards ſeparated. To procure this ſeparation of metals from ores, theſe muſt be ſo thinly liquefied, that the ſmall metallic particles may diſengage themſelves from the ſcoria; but it muſt not be ſo thin as to allow the metal to precipitate before it be perfectly diſengaged from any adhering extraneous matter, or to pervade and deſtroy the containing veſſels and furnace. Some ores are ſufficiently fuſible; but others require certain additions, called *fluxes*, to promote their fuſion, and the vitrification of their unmetallic parts; and alſo to render the ſcoria ſufficiently thin to allow of the ſeparation of the metallic particles.

Different fluxes are ſuitable to different ores, according to the quality of the ore, and of the matrix, or ſtone adherent to it.

The matrixes of two different ores of the ſame metal frequently ſerve as fluxes to each other; as, for inſtance, an argillaceous matrix with one that is calcareous; theſe two earths being diſpoſed to vitrification when mixed, though each of them is ſingly infuſible. For this reaſon, two or more different ores to be ſmelted are frequently mixed together.

The ores alſo of different metals require different fluxes. Thus, calcareous earth is found to be beſt ſuited to iron ores, and ſpars and ſcoria to fuſible ores of copper.

The fluxes moſt frequently employed in the ſmelting of ores, are calcareous earth, fluors or vitreous ſpars, quartz, and ſand, fuſible ſtones, as ſlates, baſaltes, the ſeveral kinds of ſcoria, and pyrites.

Calcareous earth is uſed to facilitate the fuſion of ores of iron, and of ſome of the poorer ores of copper, and, in general, of ores mixed with argillaceous earths, or with felſpar. This earth has been ſometimes added with a view of ſeparating the ſulphur, to which it very readily unites: but by this union, the ſulphur is detained, and a hepar is formed, which readily diſſolves iron and other metals, and ſo firmly adheres to them, that they cannot be ſeparated without more difficulty than they could from the original ore. This addition is therefore not to be made till the ſulphur be previouſly well expelled.

Fluors, or fuſible ſpars, facilitate the fuſion of moſt metallic minerals, and alſo of calcareous and argillaceous earths, of ſteatites, aſbeſtus, and of ſome other infuſible ſtones, but not of ſiliceous earths without a mixture of calcareous earth.

Quartz is ſometimes added in the fuſion of ferruginous copper ores, the uſe of which is ſaid chiefly to be, to enable the ore to receive greater heat, and to give a more perfect vitrification to the ferruginous ſcoria.

The fuſible ſtones, or ſlates, baſaltes, are ſo tenacious and thick when fuſed, that they cannot be conſidered properly as fluxes, but as matters added to leſſen the too great liquidity of ſome very fuſible minerals.

The ſcoria obtained in the fuſion of an ore is frequently uſeful to facilitate the fuſion of an ore of the ſame metal, and ſometimes even of the ores of other metals.

Sulphurated pyrites greatly promotes the fuſibility of the ſcoria of metals, from the ſulphur it contains. It is chiefly added to difficultly fuſible copper ores, to form the ſulphureous compounds called *matts*, that the ores thus brought into fuſion, may be ſeparated from the adhering earthy matters, and that the ferruginous matter contained in them may be deſtroyed, during the ſubſequent calcination and fuſion, by means of the ſulphur.

As in the ores called *calciform,* the metallic matter exiſts in a calcined ſtate; and as calcination reduces the metals of mineraliſed ores (excepting the perfect metals) to that ſtate alſo; therefore all calciform and calcined ores require the addition of ſome *inflammable ſubſtance* to reduce them to a metallic ſtate. In great works, the charcoal or other fuel uſed to maintain the fire, produces alſo this effect.

Metals are ſometimes added in the fuſion of ores of other more valuable metals, to abſorb from theſe ſulphur and arſenic. Thus, iron is added to ſulphurated cupreous and ſilver ores. Metals are alſo added in the fuſion of ores of other more valuable metals, to unite with and collect the ſmall particles of theſe diſperſed through much earthy matter, and thus to aſſiſt their precipitation. With theſe intentions, lead is frequently added to ores and minerals containing gold, ſilver, and copper.

Ores of metals are alſo ſometimes added to aſſiſt the precipitation of more valuable metals. Thus, antimony is frequently added to aſſiſt the precipitation of gold intermixed with other metallic matters. Macquer's Chem. Dict. Eng. edit. art. *Smelting,* note *m.* See COPPER, GOLD, IRON, LEAD, SILVER, TIN, &c. See alſo Schlutter's Treatiſe on the Smelting of Ores, tranſlated from the German into French by M. Hellot, and Chem. Dict. art. *Smelting,* Eng. ed. notes *n, o, p, q.*

The following ſimple method of ſmelting is practiſed by the natives of the province of Mekran in Perſia; which, although it may, at times, leave a trifling portion of the earth mixed with the metal, is, from its ingenuity, worthy of notice. When a ſufficient quantity of the ore is collected, it is placed upon a pile of wood, which is ſet on fire, and conſtantly repleniſhed with freſh fuel, until the ore melts and falls to the bottom, when it is ſeparated from the aſhes, and found to be conſiderably clearer than when firſt taken from the mine. It is then placed in a pit, made of earthen tiles, ſo conſtructed as to admit a fire under it. The ore is again melted in this pit, and a conſiderable quantity of the droſs and dirt removed, by ſkimming the ſurface. After this proceſs, the metal is lifted out in a liquid ſtate, poured into hollow cylinders of clay, and then ſold.

SMELTING-*Houſe,* a houſe where they run and melt the ore into lead: one of theſe will run a ton in ten or twelve hours; but a fodder is their uſual day's work, that is, twenty-two hundred and an half weight.

SMELTZ, in *Geography,* a river of Pruſſian Lithuania, which runs into the Curiſh Haff, two miles S. of Memel.

SMENUS, in *Ancient Geography,* a river of the Peloponneſus, in Laconia. It had its ſource in mount Taigetes, and its mouth on the left of a very elevated promontory, upon which was a temple of Diana Dictymna, according to Pauſanias.

SMERWICK, in *Geography,* a ſmall town of the county of Kerry, Ireland, ſituated on a bay to which it gives name; 7 miles N.W. from Dingle, and 173 S.W. by W. from Dublin.

SMEW, in *Ornithology,* the Engliſh name of the common mergus, known among authors by the names of *albellus,* and *mergus cirratus.*

SMICH, in *Geography,* a river that runs into the Danube, 3 miles W. of Sigmaringen.

SMIDARY, a town of Bohemia, in the circle of Konigingratz; 3 miles N. of Biezow.

SMIHANJE, a town of Croatia; 40 miles E. of Bihacs.

SMILA, in *Ancient Geography,* a town of Greece, in the country of Croſſæa, on the confines of Thrace and Macedonia.

SMILACINA, in *Botany,* a name which, with all our reſpect for its excellent author, profeſſor Desfontaines, we cannot admit, as being fabricated from another exiſting generic name, *Smilax,* and therefore contrary to ſound Linnæan laws, and to right reaſon. The eſtabliſhment indeed of the genus itſelf, which is ſeparated from *Convallaria* merely on account of the deep diviſions of the corolla, revives an old queſtion, long ago ſet at reſt, as we preſume, by Linnæus. It would be more deſirable to diſcover a character by which the Linnæan *Convallaria,* including the *Polygonatum* and *Smilacina* of other authors, could be clearly diſtinguiſhed from one or two of its neighbours. See CONVALLARIA, the third ſection of which compriſes the *Smilacinæ* of Desfontaines, Ann. du Muſ. d'Hiſt. Nat. v. 9. 51. Purſh North Amer. v. 1. 232. The eſſential character is thus given by the author laſt cited.

Corolla inferior, in ſix deep ſpreading ſegments. Stamens diverging, inſerted into the baſe of each ſegment. Berry globoſe, of three cells. Flowers terminal, panicled, or ſomewhat umbellate.

SMILAU, in *Geography,* a town of Bohemia, in the circle of Czaſlau; 5 miles N. of Polna.

SMILAX, in *Botany,* σμιλαξ of the Greeks, a name originally belonging to the Yew, *Taxus;* but likewiſe applied by Dioſcorides, with different epithets, to ſome other plants of a climbing nature. One of theſe he terms τραχεια, *rough,* and as the name of *Smilax* remains with this, among modern botaniſts, De Theis ſuppoſes the word to originate from σμιλη, *a ſcraper.* We cannot preſume to offer any conjecture reſpecting its etymology or meaning. The σμιλαξ of Dioſcorides, ſimply ſo denominated, is ſtigmatized by him as a moſt dangerous poiſon; while his σμιλαξ τραχεια is celebrated as an antidote, ſo powerful, that if given to a new-born infant, he can never be poiſoned as long as he lives!—Linn. Gen. Ch. Male, *Cal.* Perianth widely bell-ſhaped, of ſix oblong leaves, approximated at the baſe, reflexed and ſpreading at the extremity. *Cor.* none, unleſs the calyx be taken for ſuch, (which, from the analogy of *Aſparagus, Convallaria,* &c. it ſurely ought to be.) *Stam.* Filaments ſix, ſimple; anthers oblong.

Female, *Cal.* as in the male, deciduous. *Cor.* none. *Piſt.* Germen ſuperior, ovate; ſtyles three, minute; ſtigmas oblong, reflexed, downy. *Peric.* Berry globoſe, of three cells. *Seeds* ſolitary in each cell, globoſe, one or two of them generally abortive.

Eſſ. Ch. Male, Calyx of ſix leaves. Corolla none.

Female, Calyx of ſix leaves, inferior, deciduous. Corolla none. Styles three. Berry of three cells. Seeds one, two, or three.

Obſ. Mr. Brown defines the calyx *permanent;* we find it, as Linnæus ſays, *deciduous.* RIPOGONUM (ſee that article) has the ſtamens and piſtils in the ſame flower.

Of this ample genus, Linnæus in Sp. Pl. has only thirteen ſpecies; Willdenow has forty-one. To theſe, four North American ones are added by Purſh, and Mr. Brown has four from New Holland, excluſive of the ſecond ſpecies of *Ripogonum.* They are all climbing perennial plants, with ſimple, alternate, ribbed, entire leaves, with or without tendrils; the ſtem moſtly ſhrubby, ſmooth or prickly, round or angular; flowers generally umbellate. The following examples may ſuffice.

Sect. 1. *Stem prickly, angular.* Fourteen ſpecies in Willdenow.

S. *aſpera.* Red-berried Rough Smilax. Linn. Sp. Pl. 1458. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 959, unpubliſhed. Matth. Valgr. v. 2. 551. Ger. Em. 859. (S. aſpera, rutilo fructu; Cluſ. Hiſt. v. 1. 112.)—Stem angular, very prickly. Leaves oblong-heart-ſhaped, ſomewhat haſtate, with ſeven or nine ribs, coriaceous, bordered with ſpinous teeth.—Native of hedges and thickets, throughout the ſouth of Europe. Dr. Sibthorp found it abundantly in marſhy and rough ſtony ground, in Greece and all the neighbouring iſlands, flowering late in autumn. The *ſtems* climb, by means of tendrils, like our Bryony, and hang in feſtoons from the tops of hedges. They are woody, perennial, branched, zig-zag, plentifully armed with ſtrong, ſcattered, hooked prickles, as are likewiſe the *footſtalks* and edges of the evergreen *leaves.* *Flowers* white, with a fleſh-coloured tint extended to their ſtalks, in ſmall umbellate tufts, diſpoſed in terminal, zig-zag, ſmooth *cluſters.* *Berries* of a dull ſcarlet red, the ſize of currants, umbilicated, with three ſeeds in each.—This is doubtleſs the *σμιλαξ τραχεια* of Dioſcorides; the Lofty, or Woody, Bramble of the modern Greeks.

The figure in Plukenet's *Phytographia*, t. 110. f. 3, indicated as a variety, is hardly ſuch, but exhibits nearly the uſual form of the *leaves;* what has been generally taken for *S. aſpera* being in fact the following ſpecies, whoſe *leaves* are always broader.

S. *nigra.* Black-berried Rough Smilax. Willd. n. 2. Prodr. Fl. Græc. n. 2313, unpubliſhed. (S. aſpera β; Linn. Sp. Pl. 1458. S. aſpera nigro fructu; Cluſ. Hiſt. v. 1. 113. S. aſpera luſitanica; Ger. Em. 860.)—Stem angular, prickly. *Leaves* oblong-heart-ſhaped, ſeven-ribbed, coriaceous, ſmooth at the edges.—Native of hedges in Spain, Portugal, and the ſouth of France. Dr. Sibthorp obſerved it about Pruſa, in Bithynia. The *ſtems* are leſs prickly than in the former; the *leaves* broader, not at all dilated at the ſides, nor contracted in the middle, ſo as to approach a haſtate form; their edges very ſlightly, or not at all, prickly; and the *berries* are black.

S. *excelſa.* Tall Smilax. Linn. Sp. Pl. 1458. Willd. n. 5. Ait. n. 2. Prodr. Fl. Græc. n. 2314, unpubliſhed. (S. orientalis, ſarmentis aculeatis, excelſas arbores ſcandentibus, foliis non ſpinoſis; Tourn. Cor. 45. Buxb. Cent. 1. 18. t. 27.)—Stem angular, prickly. Leaves ovate, ſlightly heart-ſhaped, with five or ſeven ribs, and no marginal prickles.—Native of the country near Conſtantinople. Gathered by Dr. Sibthorp in woods at the village of Belgrad. Buxbaum ſays it is frequent in hedges about villages in Thrace, as well as in Pontus and Cappadocia, and that it is very uſeful for fences and ſhade. The *flowers* are yellowiſh-green; the *berries* red.

Whether *S. aſpera,* Alpin. Egypt. 141, cited with doubt by Linnæus, be this plant, is not clear to us. Willdenow thinks it a diſtinct ſpecies, not yet deſcribed by ſyſtematic writers.

S. *Sarſaparilla.* Medicinal Smilax, or Sarſaparilla. Linn. Sp. 1459. Willd. n. 9. Ait. n. 4. Purſh n. 5. Woodv. Med. Bot. t. 194. (S. peruviana, Salſaparilla; Ger. Em. 859.)—Stem prickly, ſomewhat quadrangular. Leaves elliptical, pointed, abrupt, three-ribbed; without prickles; ſlightly glaucous beneath. Common flower-ſtalk longer than the footſtalk.—Common in the hedges and ſwamps of North America, flowering in June and July. *Purſh.* The *ſtem* is ſtout, a little zig-zag, roundiſh, with about four ſlight unequal angles, and a few ſcattered hooked prickles. Full-grown *leaves* nearly orbicular, two and a half inches broad, abrupt or contracted at each extremity, with a ſhort terminal point; their ſurface finely reticulated with veins, and marked with three ſtrong ribs, the lateral ribs deſcribed by Willdenow hardly deſerving to be ſo denominated. *Footſtalks* ſhort, broad, channelled, each crowned with two tendrils, ſubſequently deciduous. *Flowers* yellowiſh-white, in axillary, ſolitary, ſtalked umbels. *Berries* red, according to Woodville, whoſe figure, the only one extant, has not been noticed, his work being never quoted by Mr. Aiton, though it ſurely ranks high as an uſeful medical book, and the plates, by Mr. Sowerby, are, as far as poſſible, original. It is much to be wiſhed that what are merely done from dried ſpecimens, or from other authors, had been every where ſo acknowledged, by which the authority of the publication would have been unimpeachable, and on a par with any whatever. For the hiſtory, and medical qualities, of the root, ſee SARSAPARILLA.

S. *melaſtomifolia.* Rough-ribbed Smilax.—Stem with many angles, denſely and minutely prickly; as well as the ſeven ribs of the ovate, pointed, ſlightly heart-ſhaped, rough-edged leaves.—Gathered by Mr. Menzies, in the Sandwich iſlands. A fine new ſpecies, whoſe *branches* are zig-zag, nearly round, with numerous angles, all copiouſly beſet with minute, ſtraight, rigid prickles. *Leaves* three inches long, and near one and a half broad, with five principal ribs, and a pair of ſlender, wavy marginal ones. Theſe all bear underneath copious prickles, like thoſe of the *branches* and *footſtalks,* ranged in ſeveral rows on the larger ribs. The reticulated veins are alſo rough with prickles, ſo that the leaf altogether reſembles that of ſome ſpecies of *Melaſtoma.* *Umbels* axillary, ſtalked, one or more from each leaf, accompanied by large concave, ſheathing *bracteas.*

Sect. 2. *Stem prickly, round.* Nine ſpecies in Willdenow.

S. *auſtralis.* Strong-veined New Holland Smilax. Br. n. 1.—Stem round, with copious prickles. Leaves ovate-oblong, acute, five-ribbed, ſmooth, without prickles. Tendrils in pairs on the footſtalks.—Gathered by Mr. Brown, near Port Jackſon, New South Wales. We received from Kew garden, in 1798, a ſpecimen in flower of what we preſume to be this ſpecies. It is diſtinguiſhed by the copious, ſtrong, ſtraight prickles, of its round, ſlightly ſtriated, zig-zag *branches.* The *leaves* are rigid and coriaceous, ſmooth, with five ribs, and innumerable prominent reticulated veins; their baſe ſomewhat heart-ſhaped; the *footſtalks* ſhort, broad, channelled, bearing from the middle two long ſpiral *tendrils.* *Flowers* white, numerous, in axillary umbels, whoſe ſtalks rather exceed the footſtalks.

S. *China.* Chineſe Smilax, or China-root. Linn. Sp. Pl. 1459. Willd. n. 15. Ait. n. 5. Woodv. Med. Bot. t. 236. (Sankira, vulgò Quáquara; Smilax minùs ſpinoſa, fructu rubicundo, radice virtuoſâ, *Chinæ* dictâ; Kæmpf. Amoen. 781. t. 782. Frutex convolvulaceus ſpinoſus ſinicus, &c.; Pluk. Amalth. 101. t. 408. f. 1. China vulgaris officinarum; Ger. Em. 1618.)—Stem roundiſh, with ſcattered prickles. Leaves roundiſh-ovate, acute at each end, with three principal ribs.—Native of China and Japan; ſaid to have been cultivated by Miller, in 1759. The *ſtem* is ſtrongly zig-zag. *Leaves* one and a half or two inches long, and nearly as broad, ſmooth, with three ſtraight principal ribs, and two wavy, more ſlight, lateral ones. *Footſtalks* bearing two, or more, long twiſted *tendrils.* *Flowers,* according to Kæmpfer, greeniſh-yellow, in umbels, on ſlender, ſolitary, axillary ſtalks, longer than the footſtalks. *Berries* the ſize of black currants, ſcarlet, mealy, auſtere like a medlar, ſaid to contain four, five, or ſix *ſeeds*, a greater number than uſual in this genus. We ſtrongly ſuſpect that more than one ſpecies is confounded under the hiſtory of this ſpecies. The Linnæan Chineſe ſpecimens have more heart-ſhaped *leaves* than any of the figures exhibit, nor is their *ſtem* prickly. Very poſſibly, however, theſe do not belong to the officinal China-root.

This root was brought into Europe, towards the middle of the 16th century, with ſtrong recommendations of its virtues, as a cure for the venereal diſeaſe, as well as for various chronic, cutaneous, or rheumatic diſorders. Theſe are neither confirmed by experience, nor rendered probable by the ſenſible qualities of the root itſelf, which is farinaceous and nearly inſipid.

S. *caduca*. Deciduous Smilax. Linn. Sp. Pl. 1460. Willd. n. 22. Ait. n. 9. Purſh n. 12.—Stem round, with diſtant ſtraight prickles; branches angular. Leaves ovate, pointed, five-ribbed. Common flower-ſtalks hardly longer than the footſtalks. Tendrils capillary, much ſhorter than the leaves.—In dry fields, from Canada to Virginia, flowering in June. *Purſh*. The *ſtem* is rather ſtout, quite round when full-grown, but the *branches* are decidedly angular, and ſtrongly zig-zag. *Prickles* diſtant, ſtout, tipped with black. *Leaves* broadly ovate, or ſlightly heart-ſhaped, ſmooth, green on both ſides, very finely veined, their lateral ribs often obſolete. *Tendrils* very ſmall and ſlender, from the middle of each footſtalk. *Flowers* few, greeniſh, in ſolitary *umbels*.

S. *ſpinuloſa*. Briſtly Smilax.—Stem round, with crowded, capillary, curved prickles; branches ſomewhat angular. Leaves ovate-oblong, pointed, five-ribbed; glaucous beneath. Tendrils capillary.—Sent from Pennſylvania, by the late Rev. Dr. Muhlenberg, who thought it had been improperly confounded with *S. caduca*. The quantity of fine ſetaceous prickles, on the *ſtem* or *branches*, ſeems to be variable; but the more oblong *leaves*, opaque and glaucous beneath, are very different from the laſt. We cannot refer this to any of Mr. Purſh's ſpecies.

Sect. 3. *Stem without prickles, angular.* Seven ſpecies in Willdenow.

S. *latifolia*. Broad-leaved Smilax. Br. n. 4. Ait. n. 11. —"Stem angular, without prickles. Leaves ovate, five-ribbed, ſmooth; ſomewhat heart-ſhaped or obtuſe at the baſe. Footſtalks bearing the tendrils."—Gathered by Mr. Brown in the tropical part of New Holland. Sent to Kew, in 1791, by ſir Joſeph Banks. It is there treated as a greenhouſe plant, but has not yet flowered.

S. *herbacea*. Herbaceous Smilax. Linn. Sp. Pl. 1460. Willd. n. 27. Ait. n. 12. Purſh n. 16. (S. claviculata hederifolia tota lævis, e terrâ Marianâ; Pluk. Phyt. t. 225. f. 3, marked 4.)—Stem herbaceous, angular, ſimple, erect. Leaves oval, ſeven-ribbed. Tendrils from the baſe of the long footſtalks. Common flower-ſtalks very long, compreſſed.—In dry fields, on the edges of woods, from New York to Carolina, flowering in June and July. *Purſh*. The *root* is perennial. *Stems* annual, browniſh-purple, ſmooth, with a pair of revolute *tendrils* to each leaf. *Umbels* globoſe, of numerous *flowers*, on axillary ſtalks, near ſix inches long. *Berries* dark purple, depreſſed.—Plukenet's figure, if rightly quoted, is a very bad one, the *leaves* being not ſufficiently elliptical, and the *footſtalks* much too ſhort.

Sect. 14. *Stem without prickles, round.* Eleven ſpecies in Willdenow.

S. *elliptica*. Elliptical Smilax. Br. n. 3.—"Stem without prickles; branches round, ſtriated. *Leaves* elliptic-ovate, ſomewhat pointed, five-ribbed, ſmooth; rather acute at the baſe. Footſtalks bearing the tendrils."—Gathered by Mr. Brown in the tropical part of New Holland.

S. *glyciphylla*. Sweet-leaved Smilax. Smith in White's Voyage, 230. t. 24. f. A, B. Br. n. 2.—Stem round, without prickles. Leaves ovate-oblong, acute, three-ribbed, ſmooth, ſomewhat revolute; glaucous beneath. Footſtalks bearing the tendrils.—Sent from the neighbourhood of Port Jackſon, New South Wales, among the firſt communications from thence. The *leaves*, having a very ſweet taſte, like liquorice-root, accompanied with ſome bitterneſs, were uſed by the firſt ſettlers in that country, to make a ſort of tea, which was thought good for the ſcurvy. The *ſtem* is wiry, ſmooth, and ſlender. *Leaves* about two or three inches long, reticulated, coriaceous; broad and rounded at the baſe, on ſhortiſh curved *footſtalks*. *Flowers* in axillary, ſtalked umbels.

S. *Pſeudo-china*. Baſtard Virginian China-root. Linn. Sp. Pl. 1461. Willd. n. 38. Ait. n. 15. Purſh n. 10, excluding Sloane's ſynonym. (S. virginiana, ſpinis innocuis armata, latis canellæ foliis, radice arundinaceâ craſſâ et carnoſâ; Pluk. Phyt. t. 110. f. 5. China ſpuria nodoſa; Bauh. Pin. 297. Pſeudo-china radix ex Virginia; Cluſ. Exot. 83.) —Stem round, without prickles. Leaves ovate, pointed, five-ribbed. Tendrils from the baſe of the footſtalks. Common flower-ſtalks longer than the leaves.—In ſandy fields and dry woods, from New Jerſey to Carolina, flowering in May and June. A *ſhrub*. The *roots* very large, ſearched after by hogs. *Purſh*. The *ſtem* is of a purpliſh-brown, very ſmooth. *Branches* long, ſlender, leafy, climbing by means of ſlender, not very long, *tendrils*, ſpringing in pairs from the very baſe of the angular *footſtalks*. *Leaves* two inches, or 2½, in length, an inch or more in breadth, ſlightly heart-ſhaped at the baſe, undulated or criſped, but hardly crenate, at the margin, reticulated with veins, which, as well as the ribs, are ſometimes rough with minute prickles beneath. *Flower-ſtalks* axillary, umbellate, longer than the leaves.—The *root* of this ſpecies is ſaid to have been brought from Virginia for the true China-root, of which we have ſpoken under the ſecond ſection. They ſeem to agree in their farinaceous or ſtarch-like ſubſtance, which, it ſeems, is common to the roots of various other plants of this genus. Sloane deſcribes one under the name of S. aſpera, fructu nigro, radice nodoſâ, magnâ, lævi, farinaceâ, China dictâ; Sloane Jam. v. 1. 231. t. 143. f. 1. This, he ſays, has a *root* as thick as a man's leg, crooked and ſwelling, with a thin red-brown ſkin, and a friable light red internal ſubſtance, giving a reddiſh tincture to water. Its qualities are like the real China-root, in the place of which Sloane recommends its uſe, at leaſt in the Weſt Indies. Linnæus cites this ſynonym under his *S. Pſeudo-china*, with which it has little connection; and he refers alſo to the S. aſpera, foliis trinerviis oblongis, petiolis biclaviculatis, Browne's Jamaica, 359, a ſpecimen of which is attached, in the Linnæan herbarium, to the real *S. Pſeudo-china*. The *leaves* of this are elliptical. Common *flower-ſtalks* extremely ſhort. *Tendrils* from the middle of each *footſtalk*. *Stem* angular; ſaid to be prickly in the lower part. By theſe latter characters this plant of Browne ſhould belong to the firſt ſection; while Sloane's, deſcribed with a round and very prickly *ſtem*, muſt be referred to the ſecond. Moreover, Browne's is deſcribed with ſlender branching *roots*, and we muſt preſume that his *Smilax*, n. 1, is rather Sloane's plant, as Mr. Lunan, in his Hortus Jamaicenſis, v. 1. 180, makes it. We do not chooſe to run the riſk of determining theſe ſeveral ſpecies, without authentic ſpecimens, more eſpecially as Dr. Swartz has left them untouched. Two more of this tribe are repreſented in

Plumier's *Icones*, t. 82 and 84, which cannot be referred to any of the before-mentioned. The latter, indeed, is thus adopted by Willdenow.

S. *macrophylla*. Large-leaved Smilax. Willd. n. 39.—(China altera, non aculeata, foliis amplioribus; Plum. Ic. 73. t. 84.)—Stem round, without prickles.—Leaves ovate, obtuſe, ſomewhat heart-ſhaped, ſeven-ribbed. Tendrils from the middle of the ſhort footſtalks.—Native of the Weſt Indies. The *leaves* nearly agree in ſize and ſhape, as well as the *footſtalks*, with *Paſſiflora alata*. The *umbels* are axillary, ſolitary, on ſtalks twice the length of the *footſtalks*.

Smilax, in *Gardening*, contains plants of the ſhrubby, climbing, evergreen kinds, of which the ſpecies cultivated are, the rough ſmilax (S. aſpera); the tall ſmilax (S. excelſa); the medicinal ſmilax, or ſarſaparilla (S. ſarſaparilla); the bay-leaved ſmilax (S. laurifolia); the black bryony-leaved ſmilax (S. tamnoides); the herbaceous ſmilax (S. herbacea); the Chineſe ſmilax (S. china); and the baſtard Chineſe ſmilax (S. pſeudo-china.)

In the firſt ſort there is a variety which has the leaves eared at the baſe.

Method of Culture.—The ſix firſt hardy ſorts may be increaſed by ſlipping the roots, layers, and ſeed. In the firſt mode, the ſtalks ariſing from the roots ſhould be ſlipped with roots to each in the autumn, and be planted out either in nurſery-rows for a year or two, or, which is better, where they are to grow. In the layer method, the ſtalks ſhould be laid down in the common manner in autumn, and when well rooted, in the autumn following be taken off and planted out as above. The ſeed ſhould be obtained from abroad, and be ſown in pots filled with fine mould in the ſpring, being plunged in a hot-bed to forward their coming up; when the plants have attained ſome growth they ſhould be planted out and managed as the others.

The two laſt tender ſorts may be increaſed by layers of the young ſhoots, and dividing the roots, which ſhould be laid down, or planted out in the ſpring ſeaſon, in order to have the culture of other woody greenhouſe plants of the ſame nature. The layers will be ready to take off in the ſpring following.

The firſt ſorts are proper for ſhady ſituations, borders, &c. and the latter afford variety in the greenhouſe collections, among others of ſimilar growths.

SMILE', in *Surgery*, a lancet.

SMINTHEAN, Smintheus, σμινθευς, in *Antiquity*, an epithet given to Apollo; from the Greek σμινθος, *a rat*. There are two different accounts of the origin of this appellation: the firſt is, that, in the city of Chryſa in Myſia, was a prieſt of Apollo, called *Crinis*, with whom that god being offended, ſent a herd of rats to ſpoil all his lands; but Crinis appeaſing the deity, he came in perſon to his aſſiſtance, took up his lodgings with Crinis's ſhepherd, told him who he was, and deſtroyed all the rats with his arrows; in memory of which Crinis built a temple to his deliverer, under the name of *Apollo Smintheus*.

Strabo (l. 13.) ſays, that in Chryſa was to be ſeen a ſtatue of Apollo by the hand of Scopas, the celebrated ſtatuary of Paros, with the figure of a rat near his feet; and Heraclides of Pontus aſſerts, that the rats about that temple were ſacred.

Clemens Alexandrinus, in his exhortation to the Greeks, gives us a different ſtory. The Cretans, ſays he, intending to ſend out a colony, conſulted the oracle of Apollo as to the place: the anſwer was, that they ſhould fix their colony where thoſe born of the earth ſhould oppoſe them. Upon their arrival in the Helleſpont, the rats, in the night-time, gnawed aſunder all the ſtrings of their bows: this they deemed an accompliſhment of the oracle, and there built a city called *Smintha*.

SMINTO, Sminthium, in *Ancient Geography*, a town of Aſia Minor, in the Troade, or, as Strabo ſays, in the territory of Adramyttium. But its true name was *Chryſa*. (See Sminthean.) M. d'Anville has placed Sminthium at a ſmall diſtance S. of Tros, or Troy: according to Homer, this town was in an iſland. It gave name to a neighbouring mountain, called "Sminthium Nemus." Steph. Byz.

SMIRIS, in *Natural Hiſtory*. See Emery.

SMIRSITZ, in *Geography*, a town of Bohemia, in the circle of Konigingratz; 6 miles N.E. of Konigingratz. N. lat. 50° 14'. E. long. 15° 42'.

SMITH, Adam, in *Biography*, a diſtinguiſhed writer in moral and political philoſophy, was born in the year 1723, at Kirkaldy, in Fifeſhire, where his father held the comptrollerſhip of the cuſtoms. He received his early education under the care of his mother, then a widow, at the ſchool of Kirkaldy, where he was noticed for an extraordinary paſſion for reading. At the age of fourteen he was removed to the univerſity of Glaſgow, in which he ſpent three years, attending, among the other lectures, thoſe of the celebrated profeſſor Hutcheſon. In 1740 he was ſent as a penſioner to Baliol college, Oxford. Here he ſpent ſeven years, and it is thought that during this period he employed himſelf chiefly in acquiring an exact knowledge of the languages, ancient and modern, and in cultivating an Engliſh ſtyle, by the practice of tranſlating works of high reputation into his own language. Upon quitting the univerſity he abandoned all thoughts of entering into the Engliſh church, for which purpoſe he had been ſent thither, and went to Edinburgh, and found a friend and patron in lord Kaimes. In 1751 he was elected profeſſor of logic at Glaſgow, from which he was removed, in the following year, to that of moral philoſophy. He now felt that he was in a ſituation accommodated to his talents and diſpoſition, and in later life he was accuſtomed to ſpeak of his reſidence and employment at Glaſgow as the moſt uſeful and happieſt portion of his life. His lectures, both logical and moral, were extremely popular; and his manner of delivering them, if not graceful, was ſaid to be highly impreſſive. In thoſe on moral philoſophy were contained the rudiments of his two moſt celebrated works as an author. Of theſe, the firſt is entitled "The Theory of Moral Sentiments," and appeared in the year 1759. The fundamental principle is ſympathy, which the author makes the ſource of our feelings concerning the propriety or impropriety of actions, and their good or ill deſert. To this work he afterwards ſubjoined "A Diſſertation on the Origin of Languages." Theſe works were extremely well received, and gave him a place among the beſt writers of the time. They alſo made him known to ſeveral eminent characters; and it was in conſequence of the reputation thus acquired, that he was engaged to accompany the duke of Buccleugh in his travels. He of courſe reſigned his office as profeſſor, and in the beginning of the year 1764, he ſet out for the continent. He had now an opportunity of comparing the ideas which he had already formed reſpecting political economy, with thoſe of the ableſt men in foreign countries, and alſo with facts that preſented themſelves to his obſervation in the courſe of his travels. A long reſidence in France introduced him to the acquaintance of Turgot, Queſnai, Necker, D'Alembert, Helvetius, Marmontel, and others, to whoſe particular notice he was recommended by his countryman David Hume, with whom he had long been in habits of friendſhip. He returned to his own country in the autumn of 1766, and the following ten years he paſſed in retirement with his mother at the obſcure town of Kirkaldy. Here he was habitually employed in reading, the fruits of which were at length given to the world in his celebrated "Inquiry into the Nature and Cauſes of the Wealth of Nations." This work has long been a ſtandard work, not only in our own country, but throughout Europe. It has been ſtudied and referred to by all who pay attention to the important political topics on which it treats. After the publication of this "Inquiry," he ſpent a great part of two years in London, where his ſociety was courted by perſons of the higheſt rank in the philoſophical and literary world. In the year 1778 he obtained, through the intereſt of the duke of Buccleugh, the lucrative place of a commiſſioner of the cuſtoms of Scotland, in conſequence of which he removed to Edinburgh, which was thenceforth the place of his reſidence. His mother, who lived to a great age, ſpent her laſt days with him here. After the death of his friend, Mr. Hume, he publiſhed that philoſopher's memoirs of his own life, with ſome additions, in which he expreſſed himſelf ſo favourably with regard to the character and opinions of the deceaſed, that it was readily inferred his own ſentiments with reſpect to revealed religion could not be very different from thoſe of his friend, which drew upon him an attack in an anonymous letter, ſince known to have been from the pen of the late Dr. Horne, afterwards biſhop of Norwich. In 1787 he was appointed rector of the univerſity of Glaſgow, and in 1790 he died, at the age of ſixty-ſeven. A few days before his death he cauſed all his papers to be burnt, except a few Eſſays, which have ſince been publiſhed.

Dr. Smith was a man of great ſimplicity of character, ſubject to abſence of mind in ſociety, and fitter for ſpeculative than active life. He was much beloved by his friends, and poſſeſſed a calm and benignant diſpoſition. Of the originality and comprehenſiveneſs of his views, the extent, variety, and the correctneſs of his information, and the inexhauſtible fertility of his invention, he has left laſting monuments behind him. To his private worth, the moſt certain of all teſtimonies may be found in that confidence, reſpect, and attachment, which followed him through all the various relations of life. When perfectly at eaſe, and when warmed with converſation, his geſtures were animated and not ungraceful; and in the ſociety of thoſe whom he loved, his features were often brightened by a ſmile of inexpreſſible benignity.

Smith, Edward, one of the minor Engliſh poets, born in 1668, near Tenbury, Worceſterſhire, was the ſon of Mr. Neale, a merchant, by the daughter of lord Lechmere. The connection of his parents was dubious, or at leaſt unavowed; for after his father's death, being left to the care of Mr. Smith, who had married his paternal aunt, he aſſumed his guardian's name, by which he was ever afterwards known. He was indeed, when grown to mature years, acknowledged by his mother as her legitimate ſon, but he derived no advantage from this declaration. He was educated at Weſtminſter ſchool, under Dr. Buſby, who is ſaid to have formed a high opinion of his talents, and, in conſequence of this opinion, to have detained him longer than the uſual time under his tuition. From Weſtminſter he was elected to Trinity college, Cambridge, but having at the ſame time an invitation from Chriſtchurch college, Oxford, he preferred the latter, and became a ſtudent of that college. Here he diſtinguiſhed himſelf by Latin verſes, written on ſome public occaſions; and a Latin ode, which he compoſed in 1691, on the death of Dr. Pococke, the learned Orientaliſt, obtained for him much celebrity for a poetical imagination. In 1705 he was expelled from his college, on account of his intemperance and licentious conduct. He had, however, previouſly to this, taken his degree of M.A. He now went to London, where his wit and convivial powers cauſed him to be much careſſed by perſons of eminence, eſpecially of the Whig party; though neither his manners, nor his external appearance, rendered him adapted to good ſociety. In 1708 he publiſhed a "Poem to the Memory of Mr. John Phillips," which is ſaid to be the only one of his miſcellaneous pieces that merits notice. It has been much admired, becauſe it partakes more of ſatire than elegy. In the following year he produced his tragedy of Phædra and Hippolitus, which was not very well received. Addiſon, however, wrote the prologue, and Prior the epilogue; the principal actors took parts in it, and it was patroniſed by men of high rank, yet it was ſcarcely heard to the third night. "It has," ſays the critic, "more poetical than dramatic merit, and is greatly inferior, in point of delicacy, pathos, and conduct, to Racine's tragedy on the ſame ſubject." Mr. Smith died in the forty-ſecond year of his age, and his early death was imputed, probably with great juſtice, to his intemperate habits. He had attained much harmony of verſification as a poet, and poſſeſſed a certain luxuriance of fancy, but he gives no indication of a higher genius; and did very little for the intereſts of literature. He was lifted to temporary fame by the efforts of academic partiality, but has now ſunk to the level of many who are well nigh forgotten. Johnſon's Lives of the Poets.

Smith, *Sir* Thomas, an eminent ſcholar and ſtateſman of the 15th century, was born at Saffron-Walden, in Eſſex, in 1524. He was educated for, and ſent early to, Queen's college, Cambridge, and by his proficiency in learning obtained a penſion as king's ſcholar. Being choſen fellow of his college, he was appointed, in 1535, to read the public Greek lecture, on which occaſion he concurred with Cheke in introducing an improved mode of pronouncing that language. In 1539 he travelled to the continent, for the ſuperior advantages offered by the foreign univerſities, and at Padua he ſtudied the civil law, in which faculty he graduated. On his return he reſumed his reſidence at Cambridge, where, in 1542, he was admitted to the degree of doctor, and was nominated king's profeſſor in civil law. He purſued with great ardour his ſcheme of reforming the pronunciation of the Greek, and he likewiſe attended to the improvement of his native tongue, and publiſhed a work concerning its correct orthography and pronunciation. He was a promoter of the principles of the reformation in religion, and did his utmoſt to ſhelter thoſe reformers who were expoſed to the perſecution of the tyrant Henry VIII. He had himſelf taken orders, poſſeſſed a rectory, and alſo the deanery of Carliſle. On the acceſſion of the virtuous Edward VI., he was taken into favour by the protector Somerſet, and raiſed to ſeveral lucrative poſts, and in 1548 he was knighted, and appointed ſecretary of ſtate. On the diſgrace of the protector he was deprived of the ſecretaryſhip, but was ſoon replaced in it, and continued during the remainder of the reign in truſt and honour. When Mary ſucceeded to the throne he loſt all his offices, and was forbidden to quit the kingdom; but by his caution and prudence he was enabled to ſteer in ſafety through the ſtormy and perilous period. As ſoon as Elizabeth became queen he was invited to court, and reinſtated in the deanery of Carliſle, and employed in various public concerns, particularly in the reviſion of the Liturgy. He was ſent on various embaſſies to the court of France, and during one of his reſidences in that country he compoſed his work "On the Commonwealth of England." Owing to ſome diſappointment he retired to the country, where he ſpent three years, exerciſing the duties of a magiſtrate, and diſtinguiſhing himſelf by his ſeverity againſt ſuppoſed witches. In 1571 he returned to court, was nominated a privy counſellor, and made aſſiſtant to lord Burghley, in his office of ſecretary of ſtate. In 1572 he was employed to negociate an alliance with France, and after his return he ſucceeded lord Burghley, who was advanced to the poſt of treaſurer. He died in 1577, at the age of 63. Sir Thomas Smith is characteriſed by his eulogiſt, as "a maſter of various languages, ancient and modern, and as extremely well verſed in ſeveral ſciences. He was pious, upright, and benevolent, and ſeems to have been perfectly free from the duplicity and craft which were too frequent in the ſtateſmen of that age." He is chiefly known as a writer by the "Commonwealth of England," already referred to. Several of his letters have been printed in different collections, and four of his orations, on queen Elizabeth's projected marriage, are annexed to his Life by Strype. Biog. Brit.

SMITH, THOMAS, a learned writer, was born at London in 1638. He was admitted of Queen's college, Oxford, in 1657, and after taking his degree in arts, was choſen, in 1663, maſter of the free-ſchool adjoining to Magdalen college. He became fellow of that college in 1666, and was diſtinguiſhed for his great knowledge in the Oriental languages. He accompanied the Engliſh ambaſſador to Conſtantinople in 1668, and afterwards lived ſeveral years as chaplain with ſir Joſeph Williamſon, ſecretary of ſtate. He quitted him without any preferment, and was earneſtly ſolicited by ſeveral eminent clergymen, his particular friends, who knew his value, to return to the Levant, in order to collect MSS.; but knowing the danger attending ſuch a buſineſs, he put a negative on their propoſal. He had already made himſelf known to the learned world by a Latin diſſertation on the Chaldee paraphraſts, and their verſions, another on the Druids, and ſeveral ſermons on doctrinal points. He had alſo publiſhed ſome Latin epiſtles concerning the manners and inſtitutions of the Turks, and the ſeven churches of Aſia; of which he afterwards printed an Engliſh tranſlation; and in 1680 he publiſhed an account of the Greek church. To theſe works, relative to what he had obſerved in the Eaſt, may be added ſome papers communicated by him to the Philoſophical Tranſactions, and others contained in a collection of tracts, entitled "Miſcellanea." In 1683 he took his degree of D.D., and was preſented to a college-living, which he ſoon reſigned, and continued to reſide on his fellowſhip. When James II., in 1687, ſent a mandate to Magdalen college for the admiſſion of a popiſh fellow, Dr. Smith was one of the few perſons who petitioned againſt the meaſure, but he was far from ſteady in his oppoſition; and when the king ſignified his determination to be obeyed, Dr. Smith was one of the two fellows who ſubmitted, and in conſequence preſerved their fellowſhips, while the others had the honour of being expelled. The doctor, however, did not go far enough to pleaſe his ſovereign, and was eventually expelled from his office. The ſucceeding troubles produced his reſtoration: but in 1692, refuſing to take the oaths required by the government of William and Mary, he loſt his fellowſhip and living with which he had been preſented. He thenceforth reſided chiefly in the family of ſir John Cotton, occupied in his ſtudies, and in the compoſition of a variety of works. Of theſe, the greater part was of the antiquarian and biographical claſs. In the latter, his principal publication was entitled "Vitæ quorundam eruditiſſimorum et illuſtrium Virorum," containing the lives of archbiſhop Uſher and ſeveral other eminent characters. Dr. Smith died in 1710: he is characteriſed by his biographer as a man of great induſtry and learning, but he diſplayed in his writings much party bigotry and illiberality. His Latin ſtyle is neither clear nor ſimple. Biog. Brit.

SMITH, CHARLOTTE, daughter of Nicholas Turner, eſq. a gentleman of conſiderable property in the counties of Surry and Suſſex, when very young married Mr. Smith, the ſon of a Weſt India merchant. This match was not the effect of attachment on either ſide, and was productive of much miſery, of which a long account is given in the Monthly Magazine, vol. xxiii. p. 244. The affairs of Mr. Smith not proving proſperous, ſhe, after various perſecutions from creditors, and after paſſing ſome time in the gloom of a priſon with her huſband, retired to a convent in Normandy. Here ſhe was reduced to the utmoſt indigence, yet the exertion of her talents adminiſtered to her wants. She wrote ſeveral novels, which gained her a comfortable ſubſiſtence. She died, after various changes and misfortunes of life, at Thetford, near Farnham, Surry, in the year 1806. Her principal novels are as follow: "The Romance of Real Life;" "Emmeline;" "Ethelinda;" "Celeſtina;" "Deſmond;" and "The Old Manor Houſe." They diſplay great powers of invention; and it is remarkable, that in them all ſhe has contrived to interweave much of her own perſonal hiſtory, and painted in very ſtrong colours the characters of certain rapacious perſons, to whoſe diſhoneſty ſhe aſcribed all, or at leaſt the greater part, of her ſorrows. Mrs. Smith was alſo author of poems, ſonnets, and two ſmall volumes, entitled "Converſations introducing Poetry, chiefly on Subjects of Natural Hiſtory, for the Uſe of young Perſons." Her deſcriptions are intereſting, and her ſtyle is elegant. Her ſonnets poſſeſs great beauty, and all her writings every where diſplay the powers of a fine imagination, correct taſte, and ſtrong judgment.

SMITH, GEORGE, a native of Chicheſter, born in 1714, was, in deſpite of circumſtances in every reſpect unfavourable, a devotee to the art of painting, particularly in landſcape; and by dint of determined perſeverance ſucceeded in producing ſome works which do honour to his name. He was among the firſt who reſcued the Engliſh name, in art, from the odium caſt upon it by foreigners, and prepared the way for the brilliant efforts of Wilſon. His idea of compoſition may be eſtimated from the print, which Woollett engraved after the picture for which the Society in the Adelphi gave him their higheſt premium, and which preſents a conception almoſt worthy of Claude: his colouring, indeed, did not keep pace with the deſign, and his touch was too minute and trifling. There are many prints of his other productions, ſome etched by himſelf, but the one we have mentioned is the fineſt. He died in 1766.

SMITH, ROBERT, LL.D. and D.D., was a contemporary to Barrow. After all our reſearches, we have not been able to collect any particulars relating to the place of his birth, which was probably in Lincolnſhire, and the progreſs of his early years. It appears, however, that he was admitted A.B. in 1711, A.M. in 1715, LL.D. in 1723, and S.T.P. by royal mandate in 1739. He was firſt fellow, afterwards profeſſor of aſtronomy and experimental philoſophy, of which he was made Plumean profeſſor in 1716, ſupplying the place of his couſin, the celebrated Cotes; and he ſucceeded Dr. Bentley, in 1742, in the maſterſhip of Trinity college, in the univerſity of Cambridge. He had been preceptor to William, duke of Cumberland, and was maſter of mechanics to the king. In the year 1722 he publiſhed, at Cambridge, Cotes's "Harmonia Menſurarum," with additions, in 4to.: in 1738 appeared his "Complete Syſtem of Optics, in four books, *viz.* a popular, a mathematical, a mechanical, and a philoſophical treatiſe," &c. 2 vols.

4to.: in 1747 he publiſhed at Cambridge, in 8vo., a ſecond edition of Cotes's "Hydroſtatical and Pneumatical Lectures:" and in December 1748, he publiſhed his "Harmonics," of which a ſecond edition, much augmented and improved, appeared in October 1758. The inſcription over him is H. S. E. Robertus Smith, S. T. P. Hujus Collegii Magiſter, obiit Aug. 1768, ætatis 79.

Dr. Smith left two annual prizes of 25*l.* to two commencing bachelors of arts, who were to be the beſt proficients in mathematics and natural philoſophy of the year. He alſo left 2000*l.* towards repairs of Trinity college, and 2500*l.* to the univerſity.

Dr. Smith was a performer on the violoncello, and a curious inquirer into the defects of the muſical ſcale on keyed inſtruments; which he tried to remedy by many ingenious experiments and calculations. He had a harpſichord made by Kirkman, with quarter-tones, as they are called, with only a ſingle ſtring to each note, by which means the inſtrument, not being crowded with two or three ſtrings to each, by pedals could make any key perfect, as it allowed of two ſtrings for each of the five ſhort keys, differently tuned, to each note; as F♯ and G♭, G♯ and A♭, A♯ and B♭, &c. which rendered thoſe keys delightful, and which, in the old tuning, were inſufferable. But this perfect harmony only ſuited regular and ſober modulation: the compoſitions of Haydn and Mozart, and their imitators, would want a new ſcale every two or three bars. Poor Claggett purſued this plan, and by means of multiplied ſtrings and pedals had acquired perfect intonation to all the twenty-four keys. But by additional bridges, and the preſſure of ſo many ſtrings on the belly of the inſtrument, the tone was injured and enfeebled. This, alas! but confirms the two melancholy reflections, which tell us that "we cannot have every thing;" and that, "il faut ſouffrir dans ce monde."

The great mathematician, Dr. Smith, had ſo accuſtomed himſelf to perfect harmony, that he neither could bear the throwing of the imperfections of the ſcale on the *wolf*, or E♭, nor even on two or three ſhort keys ſeldom uſed in old church muſic; but all the compound ſtops in the organ, ſuch as the ſeſquialter and cornet, and the ſingle ſtops of the twelve and the tierce in the chorus, he took out of the fine organ of Trinity college, Cambridge, built by father Smith, and reduced the whole chorus to uniſons and octaves, which was thought by many to injure the inſtrument ſo much as to bereave it of all its ſpirit, and render it inſipid. And after the deceaſe of Dr. Smith we have been aſſured, that the excommunicated pipes have been again received into the boſom of the church.

Dr. Smith's "Harmonics," already mentioned, was profeſſedly written to aſſiſt organ-builders and tuners to divide the redundancies of the ſcale equally, or nearly equally, among all the twelve ſemitones in the octave by a table of *beats*. To give the reader an idea of Dr. Smith's plan, we muſt refer him to the article BEATS, where this effect, produced by two organ-pipes nearly in tune, is explained. But Dr. Smith's treatiſe, ſo far from being intelligible to tuners of organs, and organ-players in general, requires a knowledge in geometry and fluxions, which none but great mathematicians able to read Newton's Principia poſſeſs. Yet the book is written in ſo pleaſing and alluring a ſtyle, that many peruſe as much as they are able of the unſcientific part, and give the author credit for the accuracy of his calculations.

SMITH, JOHN CHRISTOPHER, a good muſician, and a reſpectable man. He was the eldeſt ſon of the worthy John Chriſtopher Schmidt, Handel's copyiſt, ſteward, and confidential countryman, who came over with him from Germany, and lived an inmate with him to nearly the time of his death. He uſed to engage and pay the performers in the oratorios carried on by Handel himſelf; and being a good muſician, was the moſt correct copyiſt of his time.

His ſon, John Chriſtian, was a ſtudious and cultivated man, and much eſteemed by many of the firſt people in the kingdom. He was particularly regarded by the late lord Barrington, and all that noble family; and having early in life travelled with a gentleman of fortune, at Geneva he became acquainted with ſome Engliſh gentlemen of learning and talents, among whom were Mr. Price, of Foxley, Herefordſhire; Mr. Windham, of Felbrig, Norfolk; Mr. Tate, of Mitcham, Surry; and Mr. Benjamin Stillingfleet, &c. This gave him a taſte for, and procured him admiſſion into, good company; ſo that he formed his character on models of a higher claſs than that of a mere muſician.

In the Monthly Review of a pamphlet publiſhed in 1780, entitled "Anecdotes of George Frederick Handel, and of John Chriſtian Smith," there are ſome paſſages relating to the venerable Mr. Smith, which we ſhall tranſcribe, being certain that they are accurate, from our own knowledge.

"After the period of Mr. Smith's return to England, he mixed very little with his profeſſional brethren, though he continued to compoſe muſic, and to teach the harpſichord, till the year 1760; when, being in poſſeſſion, not only of the *ſcores* of Handel's oratorios, but of the ſingle vocal and inſtrumental parts, which had been tranſcribed for, and uſed by his numerous bands, Mr. Smith undertook to continue the performance of oratorios in Lent, during eight years, on his own account; and during nine more, jointly with Stanley. . . . . . .

"We have heard, from the firſt contemporary authority, that there was a ſhyneſs between Handel and the younger Smith for ſeveral years, which kept them aſunder till the great muſician loſt his ſight: but the difference was occaſioned by no dignified cauſe of quarrel. Mr. Smith, early in life, having had ſome inſtructions from Handel, though his principal maſters were Dr. Pepuſch and Roſeingrave, when about the year 1739, he publiſhed a book of harpſichord leſſons, in 4to. Handel took it amiſs that his ſcholar, the ſon of his copyiſt, ſhould preſume to have a title-page to his leſſons engraved exactly in the ſame form and text-hand with his own firſt book of "Pieces de Clavecin," the beſt of all his productions. Mr. Smith's pieces were then perhaps inferior only to thoſe of his model. They conſiſted, as was then the general faſhion, of preludes, fugues, allemandes, corants, and jigs.

"Mr. Smith was certainly an elegant muſician, and in his conduct and manners far above the general level of the profeſſors of his art; but we are not certain, that his execution as a practitioner was great, nor that his invention as a compoſer was original. It is plain, that Mr. Smith's ſtyle of compoſition was that of the day, without an attempt at deviation; a ſtyle, which Handel had rendered *à-la-mode*, and to which not only Mr. Smith, but all the Engliſh compoſers, ſtrictly adhered during more than forty years; as is manifeſt in the works of Green, Boyce, Arne, (in his oratorios,) Worgan, and Stanley. Arne, in his dramatic muſic, adopted eaſy and elegant paſſages from Italian operas; but we muſt except his Comus, in which there is much original melody, as well as in his Vauxhall ballads. Mr. Smith never was a popular compoſer. His oratorios, though new, and in ſupport of which he had the patronage of ſeveral illuſtrious friends and great families, (particularly that of Barrington,) were not heard and attended ſo well as thoſe of Handel, which had been in conſtant uſe for many years. The Engliſh opera of "The Fairies," in which Guadagni and Fraſi performed the principal parts, had a conſiderable run; but it was never revived; nor did the airs penetrate into Vauxhall, Ranelagh, Mary-le-bone, private concerts, or private families, like thoſe of Arne's Comus, or Boyce's Chaplet, after having been heard at the theatres.

Smith, *Father*, or, as the Germans write his name, *Schmidt*, brought over with him from Germany, of which country he was a native, two nephews, Gerard and Bernard, as aſſiſtants; and to diſtinguiſh him from theſe, as well as to expreſs the reverence due to his abilities, which placed him at the head of his profeſſion, he was called *Father Smith*. During the grand rebellion, moſt of the organs in the kingdom having been deſtroyed, or ſtolen out of the churches, at the reſtoration a ſufficient number of workmen for the immediate ſupply of cathedrals and pariſh churches, with organs, not being found in our own country, it was thought expedient to invite foreign builders of known abilities to ſettle among us; and the premiums offered on this occaſion brought over the ſubject of our article and Harris.

The firſt organ which Smith engaged to build for this country was for the royal chapel at Whitehall, which, being haſtily put together, did not quite fulfil the expectations of thoſe who were able to judge of its excellence. An organ is ſo operoſe, complicated, and comprehenſive a piece of mechaniſm, that to render it complete in tone, touch, variety, and power, excluſive of the external beauty and majeſty of its form and appearance, is perhaps one of the greateſt efforts of human ingenuity and contrivance. It was probably from ſome ſuch early failure, that this admirable workman determined never to engage to build an organ upon ſhort notice, nor for ſuch a price as would oblige him to deliver it in a ſtate of leſs perfection than he wiſhed. And we have been aſſured by Snetzler, and by the immediate deſcendants of thoſe who have converſed with father Smith, and ſeen him work, that he was ſo particularly careful in the choice of his wood, as never to uſe any that had the leaſt knot or flaw in it; and ſo tender of his reputation, as never to waſte his time in trying to mend a bad pipe, either of wood or metal; ſo that when he came to voice a pipe, if it had any radical defect, he inſtantly threw it away, and made another. This, in a great meaſure, accounts for the equality and ſweetneſs of his ſtops, as well as the ſoundneſs of his pipes, to this day.

Smith had not been many months here, before Harris arrived from France, with his ſon René Renatus, an ingenious and active young man, to whom he had confided all the ſecrets of his art. However, they met with but little encouragement at firſt, as Dallans and Smith had the chief buſineſs of the kingdom; but upon the deceaſe of Dallans, who died while he was building an organ for the old church at Greenwich, 1672, and of the elder Harris, who did not long ſurvive him, the younger became a very formidable rival to Smith.

For the contention between theſe eminent artiſts, at the time of erecting the admirable organ which ſtill ſtands in the Temple church, ſee Burney's Hiſt. of Muſic, vol. iii. p. 437.

Smith, Theodore, a modern and pleaſing compoſer of natural and eaſy muſic. He was a native of Germany, and publiſhed at Berlin, at 1780, three different ſets of ſonatas *à quatre main*, three in each ſet; and in 1782, ſix concertos for the harpſichord. Though a native of Germany, he reſided ſo long in England as to be ſufficiently acquainted with our language to publiſh, beſides various muſical compoſitions, a Muſical Directory, printed by Welcker in 1778, an elementary work of conſiderable merit for its arrangement and clear explanation of the firſt rudiments of a player on keyed-inſtruments.

Smith, in *Geography*, a county of America, in the diſtrict of Weſt Tenneſſee, containing 11,649 inhabitants.—Alſo, a townſhip of Pennſylvania, in the county of Waſhington, containing 1646 inhabitants.

Smith's *Inlet*, a bay on the weſt coaſt of North America, the entrance of which is nearly cloſed by rocky iſles. From the entrance into the inlet, whoſe north point lies from its ſouth point N. 20 E. about a league diſtant, it was found to extend nearly in an eaſt direction about ſix leagues; here it takes a turn to the N.E., and terminates in N. lat. 51° 24′. E. long. 232° 47½′. About three leagues within the entrance, the rocks and iſles terminated, and the inlet contracted to a general breadth of about half a mile, though in ſome places it was near twice that diſtance from ſhore to ſhore; both of which were formed by high rocky precipices covered with wood. About half way up the canal a village of the natives was diſcovered, ſuppoſed to contain 200 or 240 perſons. This was built upon a detached rock, connected with the main by a platform, and conſtructed for defence. A great number of its inhabitants, in about thirty canoes, viſited captain Vancouver's party, and allured them in various ways to viſit their habitations. They offered the ſkins of the ſea-otter, and other animals, to barter; and beſides promiſes of refreſhment, made ſigns, not eaſily miſunderſtood, that the female part of their ſociety would take pleaſure in their company. The entrance is in N. lat. 51° 20′. E. long. 232° 12′.

Smith's *Iſland*, a ſmall iſland near the eaſt coaſt of Antigua.—Alſo, a ſmall iſland in the Atlantic, near the coaſt of Virginia; part of a cluſter collectively called "Smith's Iſlands." N. lat. 37° 15′. W. long. 75° 52′.—Alſo, a large and lofty iſland in the South Pacific ocean, diſcovered by lieutenant Ball, commander of the Supply, in 1790. S. lat. 9° 44′. E. long. 161° 54′.

Smith's *Point*, a cape on the coaſt of Virginia, forming the ſouthern limit of the Potomack river. N. lat. 37° 54′.

Smith's *River*. See Staunton.

Smith's *Sound*, a bay on the eaſt coaſt of Newfoundland, bounded by Cape Bonaviſta.

SMITHERY, a ſmith's ſhop; alſo the art of a ſmith, by which iron is wrought into any ſhape by means of fire, hammering, filing, &c.

SMITHFIELD, in *Geography*, a ſmall poſt-town of Virginia, on Pagan creek, which diſcharges itſelf into James river, in the Iſle of Wight county; 85 miles S.E. of Richmond. The creek is navigable for veſſels of 20 tons.—Alſo, a poſt-town, and the capital of Johnſon county, in North Carolina, on the eaſt ſide of Neus river, on a beautiful plain, about 100 miles N.W. of Newburn. In the centre of the town is an Indian burying-place, once in the form of a cone, 16 feet high, 30 feet in diameter, but its height is now reduced to five or ſix feet.—Alſo, a town of Jefferſon county, in the ſtate of Ohio, containing 1228 inhabitants.—Alſo, a townſhip of New York, in Madiſon county, bounded north by Lenox, eaſt by Auguſta in Oneida county, ſouth by Eaton and Nelſon, and weſt by Cazenovia; erected in 1807 from Cazenovia, and about 12 miles eaſt and weſt, and 5 north and ſouth. The principal part of this tract was leaſed of the Oneida Indians by Peter Smith, 1794, and purchaſed by the ſtate in 1795. The ſoil is of a ſuperior quality, and the whole tract is one of the beſt in the ſtate. It is amply irrigated by ſmall ſtreams, and alſo by the main branch of the Chenango river, itſelf a branch of the Suſquehanna. This town is principally ſettled by emigrants from the eaſtern ſtates, and compriſes the largeſt part of the tract called New Peterſburg. The population in 1810 conſiſted of 2651 perſons. The principal village is Peterboro', ſituated on the Oneida creek. N. lat. 42° 57', and W. long. 1° 37' from New York. —Alſo, a townſhip of Pennſylvania, in Lycoming county, containing 1084 inhabitants.—Alſo, a town of Rhode iſland, in Providence county, containing 3828 inhabitants.

Smithfield, *Lower*, a townſhip of Pennſylvania, in the county of Northampton, containing 1326 inhabitants.

Smithfield, *Upper*, a townſhip of Pennſylvania, in the county of Wayne, containing 520 inhabitants.

Smithfield, *Middle*, a townſhip of Pennſylvania, in the county of Wayne, containing 682 inhabitants.

SMITHIA, in *Botany*, was ſo named, after the writer of the preſent article, in the firſt edition of the *Hortus Kewenſis*, of his ever valued and lamented friend the late Mr. William Aiton, publiſhed in 1789.—Ait. Hort. Kew. ed. 1. v. 3. 496 and 512. ed. 2. v. 4. 336. Schreb. 809. Willd. Sp. Pl. v. 3. 1161. Mart. Mill. Dict. v. 4. Lamarck Dict. v. 7. 222. Illuſtr. t. 627.—Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped; the ſegments ovato-lanceolate, concave, acute, nearly equal. *Cor.* papilionaceous. Standard inverſely heart-ſhaped. Wings oblong, obtuſe, rather ſhorter than the ſtandard. Keel linear-oblong, of one petal, cloven at the baſe, the length of the wings. *Stam.* Filaments ten, united into two equal ſets, combined at the bottom; anthers oblong. *Piſt.* Germen ſuperior, embraced by the baſe of the calyx; ſtyle capillary, permanent; ſtigma ſimple. *Peric.* Legume included within the calyx, of from four to ſeven orbicular, ſingle-ſeeded, diſtinct, muricated joints, connected with the permanent folded ſtyle, and lying horizontally over each other. *Seeds* ſolitary, kidney-ſhaped, compreſſed, ſmooth.

Eſſ. Ch. Stamens in two equal ſets. Legume of ſeveral horizontal, ſeparate joints, connected by the folded ſtyle, and incloſed in the two-lipped, equal calyx.

This genus, though eſtabliſhed under the authority of two very eminent botaniſts, Mr. Dryander and Mr. Saliſbury, who thought it peculiarly well marked, has of late been found ſo nearly to accord with the original ſpecies of *Aeſchynomene*, as to be ſcarcely diſtinguiſhable therefrom. Mr. Brown, however, who made this diſcovery, ſtill conſiders *Smithia* as diſtinct; the legume of *Aeſchynomene* being ſtraight, compoſed of a ſeries of vertical joints, connected by their edges, and projecting out of the calyx, while the latter is deeply divided. Their habits, and even the ſenſibility of their foliage, bring them ſo cloſely together, that we doubt, at leaſt, the propriety of keeping them ſeparate, though we are content, for the preſent, to leave them as we find them. Two ſpecies only of the genus before us have been obſerved.

1. S. *ſenſitiva*. Annual Smithia. Ait. Hort. Kew. ed. 1. v. 3. 496. t. 13. ed. 2. n. 1. Willd. n. 1. Saliſb. Parad. t. 92.—“Lips of the calyx entire. Cluſters ſtalked, of few flowers.”—Diſcovered in moiſt paſtures, on the coaſt of Coromandel, by J. G. Koenig, M.D., by whom ſeeds were ſent in 1785 to ſir Joſeph Banks. The plant is annual, and uſually kept in a hot-bed, or ſtove; but, according to Mr. Saliſbury, the ſeeds ſcattering themſelves in favourable ſituations, will ſometimes come up in the open ground, even in dry gravel. The *root* is tapering. *Stems* ſeveral, ſpreading, various in luxuriance, more or leſs branched, round, ſmooth, leafy. *Leaves* alternate, abruptly pinnate, of four, five, or ſix pair of elliptical, obtuſe, entire *leaflets*, about a quarter of an inch long; oblique at the baſe; glaucous beneath, their mid-rib and margins eſpecially beſet with long, briſtly, tawny, cloſe-preſſed hairs. *Stipulas* in pairs, lanceolate, membranous, ribbed; auricled and ſpurred at the baſe. The *leaves* fold together when touched, as in the *Mimoſa pudica*, but more tardily, unleſs in a very hot atmoſphere. The *flowers* are yellow, rather ſmall, with a purpliſh *calyx*, accompanied by a pair of cloſe *bracteas*, half its own length. Joints of the *legume* as ſmall as Red-poppy ſeed.

2. S. *conferta*. Cloſe-flowered Smithia.—Lips of the calyx toothed. Cluſters ſeſſile, ſhorter than the leaves.—Gathered in the tropical part of New Holland, by ſir Joſeph Banks, to whom we are obliged for a ſpecimen. This ſeems likewiſe to be an annual herbaceous plant. The *ſtems* are erect, ſlender, unbranched, round, ſmooth. *Leaves* few, diſtant, except at the top, where two or three are crowded together; their *leaflets* much as in the foregoing. *Stipulas* ſpurred, but ſcarcely auricled. *Cluſters* axillary, ſeſſile, of a very few *flowers*, whoſe *petals*, in the dried ſpecimen, are of a reddiſh or tawny hue. By the poſition of the dried *leaves* this ſpecies ſeems alſo ſenſitive; and perhaps they fold at night over the *flowers*, like thoſe of the *Lotus tetragonolobus*, celebrated for having firſt led Linnæus to conſider what he afterwards called the Sleep of Plants.

SMITHLAND, in *Geography*, a poſt-town of Kentucky, in the county of Livingſton, containing 99 inhabitants: the county contains 3575.

SMITHTOWN, a poſt-townſhip of New York, in Suffolk county, Long Iſland; 92 miles E. of New York; containing 1592 inhabitants, including 72 ſlaves. This place employs 14 veſſels principally in the trade with New York, of 30 to 100 tons burthen.

SMITHVILLE, a town of North Carolina, near the mouth of Cape Fear river; 30 miles S. of Wilmington. —Alſo, a townſhip of Chenango county, erected from a part of Greene in 1808; 13 miles S.W. of Norwich; containing 995 inhabitants, who manufacture moſt of their clothing in the houſehold way.

SMITING-Line, in a *Ship*, is a ſmall rope faſtened to the mizen-yard-arm, below at the deck, and is always furled up with the mizen-ſail, even to the upper end of the yard, and from thence it comes down to the poop. Its uſe is to looſe the mizen-ſail, without ſtriking down the yard, which is eaſily done, becauſe the mizen-ſail is furled up only with rope-yarns; and, therefore, when this rope is pulled hard, it breaks all the rope-yarns, and ſo the ſail falls down of itſelf. The word of art is, *ſmite the mizen*, (whence this rope takes its name,) that is, hale by this rope that the ſail may fall down.

SMITTL, in *Geography*, a town of Aſiatic Turkey, in Caramania; 18 miles E.N.E. of Cogni.

SMOCK, Lady's, or *Bitter Creſſes*, in *Agriculture*, a plant of the weed kind, found in coppices, and on the banks of rivers, which ſheep are ſaid ſometimes to eat. The common ſort is thought by ſome to be uſeful in epilepſies.

SMOKE, or Smoak, *Fumus*, a humid matter, exhaled in form of vapour by the action of heat, either external or internal; or ſmoke conſiſts of palpable particles, elevated by means of the rarefying heat, or by the force of the aſcending current of air, from bodies expoſed to heat; and theſe particles vary much in their properties, according to the ſubſtances from which they are produced. See Flame.

Smoke, ſir Iſaac Newton obſerves, aſcends in the chimney by the impulſe of the air it floats in: for that air, being rarefied by the fire underneath, has its ſpecific gravity diminiſhed; and thus, being determined to aſcend itſelf, it carries up the ſmoke along with it. The tail of a comet that great author takes alſo to aſcend from the nucleus, after the ſame manner. (See Comet.) Smoke of fat unctuous woods, as fir, beech, &c. makes what we call lamp-black.

Smoke, ariſing from the combuſtion of vegetables, is a mixture of water, oil, volatile ſalts, and all the gaſeous products which reſult from the combination of vital air with the ſeveral principles of the vegetable.

There are various inventions for preventing and curing ſmoky chimnies; as the æolipiles of Vitruvius, the ventiducts of Cardan, the windmills of Bernard, the capitals of Serlio, the little drums of Paduanus, and ſeveral artifices of De Lorme. See Chimney and Fire-*Places*.

In the Philoſophical Tranſactions we have the deſcription of an engine, invented by Monſieur Daleſme, which conſumes the ſmoke of all ſorts of wood, and that ſo totally, as the moſt curious eye cannot diſcover it in the room, nor the niceſt noſe to ſmell it, though the fire be made in the middle of the room. It conſiſts of ſeveral iron hoops, four or five inches in diameter, which ſhut into one another, and is placed on a trevet. A brand taken out of the fire ſmokes inſtantly, but ceaſes as ſoon as returned: the moſt fetid things, as a coal ſteeped in cat's piſs, which ſtinks abominably when taken out of the fire, yet in it makes not the leaſt ill ſcent; no more than red-herrings broiled, &c.

Smoke-*Jack*. See Jack.

Smoke-*Farthings* were the pentecoſtal or cuſtomary oblations offered by the inhabitants within any dioceſe, when they made their proceſſions to the cathedral church; which came, by degrees, into an annual ſtanding rent, called ſmoke-farthings. See Pentecostals.

Smoke-*Silver*, in our *Old Writers*. Lands were held in ſome places by the payment of the ſum of ſix-pence yearly to the ſheriff, called ſmoke-ſilver.

Smoke-ſilver and ſmoke-penny are to be paid to the miniſters of divers pariſhes as a modus, in lieu of tithe-wood; and in ſome manors, formerly belonging to religious houſes, there is ſtill paid, as appendant to the ſaid manors, the ancient Peter-pence, by the name of ſmoke-money.

SMOKEY Bay, in *Geography*, a large bay on the weſt coaſt of the entrance into Cook's river, between Cape Douglas and Point Banks.

SMOLEN, an iſland in the North ſea, on the coaſt of Norway, 25 miles in circumference. N. lat. 63° 24′. E. long. 8° 26′.

SMOLENSK, a town of Ruſſia, and capital of a government, ſituated on the Dnieper; the reſidence of a governor, and a biſhop's ſee, with very conſiderable commerce. The poſſeſſion of it has been often diſputed between the Poles and the Ruſſians. It is built on two hills, between which are a valley and river, and ſurrounded with walls, 30 feet high and 15 thick, the lower part being ſtone, and the upper brick, which trace the courſe of the hills, and encloſe a ſpace of about five miles. At every angle towers are erected. The houſes of the common people are moſtly conſtructed of wood: the number of inhabitants is ſaid to exceed 4000. The chief articles of trade are flax, hemp, timber, maſts, planks, honey, wax, hides, hogs' briſtles, and Siberian furs; 420 miles E.N.E. of Warſaw. N. lat. 54° 40′. E. long. 32° 18′.

Smolensk, a government of Ruſſia, bounded on the north by Pſovſkoe and Tverſkoe, on the eaſt by Moſcovſkaia and Kaluzſkoe, on the ſouth by Orlovſkoe and Novgorod Sieverſkoe, and on the weſt by Polotzſkoe and Mogilevſkoe; at its greateſt length 180 miles from N. to S., and 160 from E. to W. This government contains White Ruſſia, properly ſo called, and was ceded by Poland to Ruſſia, as a duchy, by a treaty, concluded in the year 1667, and confirmed in 1686. Its capital is Smolenſk. N. lat. 53° 20′ to 56° 15′. E. long. 31° to 36°.

SMOLIN, a town of Hungary; 22 miles N.N.E. of Preſburg.—Alſo, a mountain of Boſnia; 32 miles S.S.W. of Zwornick.

SMOLLET, Tobias, in *Biography*, a writer of conſiderable reputation, was born, in 1720, at Dalquhurn, in Dumbartonſhire. After a common education he was put apprentice to a ſurgeon in Glaſgow, and at the ſame time he availed himſelf of the opportunity of attending medical lectures at the univerſity. At this early period he compoſed a tragedy. In his nineteenth year he quitted Scotland for London, where he quickly obtained the ſituation of ſurgeon's mate in the navy. He ſailed in the expedition fitted out againſt Carthagena, under admiral Vernon and general Wentworth; and during the voyage he diſplayed his powers of obſervation, as well as his ſatirical turn, by the account he drew up of that ill-conducted and unſucceſsful enterprize. He was ſoon diſguſted with the ſervice in which he had engaged, and quitted it in the Weſt Indies. It had, however, been of great ſervice, by introducing him to that acquaintance with the manners and language of ſailors, of which he made the moſt amuſing exhibitions in his novels. The ſavage cruelties uſed by the king's troops after the battle of Culloden called forth Smollet's warmeſt feelings, and occaſioned his poem entitled "The Tears of Scotland," which by its ſpirit and elegance placed the author high in the rank of minor poets. It was followed by two ſatires, a ſpecies of compoſition to which the natural irritability of temper gave him a propenſity. He married, in 1747, a lady, with whom he expected a good fortune, of which, however, he received very little, and the expenſive ſtyle in which he ſet out in life brought him very ſoon into ſerious difficulties. In this emergency he had recourſe to his pen, and in 1748 he produced his firſt novel, entitled "Roderick Random," which had no doubt ſtrong alluſions to his own hiſtory, and became extremely popular. A trip to Paris, in 1750, enlarged his knowledge of the world, and gave riſe to his "Adventures of Peregrine Pickle," in which he exerted all the powers of humorous invention and delineation, though often at the expence of delicacy and morality. He now determined to purſue his profeſſion, and commenced phyſician at Bath, but he met with ſo little ſucceſs that he ſoon abandoned it, and reſumed writing as a profeſſion. His next publication was "Adventures of Ferdinand Count Fathom," which was followed by a new tranſlation of Don Quixote. In 1756 he undertook the management of a new Review, under the title of the "Critical," which, after undergoing a number of changes, ſtill exiſts. His ſatirical and acrimonious ſpirit ſoon broke out in this journal, and involved him in a quarrel with admiral Knowles, on whoſe conduct in the expedition to Rochefort he had ſpoken with great ſeverity. Smollet was proſecuted and convicted of a libel, and ſuffered the puniſhment of the law, *viz.* fine and impriſonment.

After this he wrote for the theatre an after-piece, entitled the "Repriſal, or the Tars of Old England;" this was acted at Drury-lane in 1757; and in the following year he publiſhed a haſtily written "Complete Hiſtory of England, from the Deſcent of Julius Cæſar to the Treaty of Aix-la-Chapelle," in two vols. 4to. About the ſame period he publiſhed a novel, entitled "The Adventures of Sir Launcelot Greaves," and he is ſuppoſed to have written the hiſtories of France, Italy, and Germany, in the modern part of the Univerſal Hiſtory. In 1761 he began to publiſh his

"Continuation of the Hiſtory of England," taken up at the Revolution, where Hume left it, and brought down to the year 1765.

At the beginning of the preſent reign, Dr. Smollet was an advocate in defence of the meaſures adopted by the adminiſtration, at the head of which was lord Bute, and in connection with others he publiſhed a weekly paper, called "The Briton," which was encountered by the more famous one entitled "The North Briton," ſet on foot by the well-known John Wilkes. The rancour diſplayed on both ſides diſſolved the friendſhip which had long ſubſiſted between theſe two political champions. Smollet, from ſome domeſtic afflictions, determined to viſit the continent, whither he went in 1763, and he ſpent two years in a tour through France and Italy. After his return he publiſhed, in 1766, his "Travels" in theſe countries, in a ſeries of letters, in two vols. 8vo. which contained many lively and ſenſible remarks, but which were deeply tinged with the gloomy temper of mind, which rendered him diſſatisfied and out of humour with almoſt every thing he ſaw. In 1769 he publiſhed a ſort of political romance, entitled "The Adventures of an Atom," intended to ridicule different adminiſtrations, but eſpecially that of the earl of Chatham.

Increaſing ill-health induced him, in the year 1770, to pay another viſit to Italy, accompanied by his wife, and during his laſt voyage he wrote his laſt novel, "The Expedition of Humphry Clinker," which ſome critics regard as the beſt of all his novels. He died in the neighbourhood of Leghorn, in October 1771, in the fifty-firſt year of his age. "Dr. Smollet," ſays the author of the article in the General Biography, "was undoubtedly a man of talents and great variety of powers, though he did not attain the higheſt rank in any thing. He is beſt known as a noveliſt, and they who read thoſe compoſitions for amuſement only, without much nicety of taſte, ſeldom fail of being entertained by him. Yet his portraits are often caricatures, his ſcenes of humour coarſe and extravagant, and his jeſts borrowed. As an hiſtorian, he has attained more credit for the elegance and animation of his ſtyle, than for the higher qualities of judgment, accuracy, and impartiality; and though his continuation is annexed to Hume's Hiſtory, the two writers will bear no compariſon." His poetic powers were conſiderable. His "Tears of Scotland," "Ode to Leven Water," and ſome other ſhort pieces, are poliſhed, tender, and pictureſque. His "Ode to Independence" is a loftier flight, and has perhaps few ſuperiors in the lyric ſtrain. His ſatires are vigorous, but violent and diſguſting.

SMOLNITZ, in *Geography*, a town of Bohemia, in the circle of Schlan; 12 miles W.N.W. of Schlan.

SMORGONIE, a town of Ruſſian Lithuania, in the palatinate of Wilna.

SMORZATO, in *Italian Muſic*, for the violin family, implies that the bow ſhould be drawn or preſſed to its full length, not with the ſame force throughout, but lighter by degrees, till ſcarcely any ſound is heard. This term ſeems now ſuperſeded by *diminuendo* and *perdendoſi*.

SMOSTRIE, in *Geography*, a town of Poland, in Podolia; 15 miles N. of Kaminiec.

SMOTHER-FLY, in *Agriculture*, a provincial term applied to the bean aphis.

SMOTRZICZ, in *Geography*, a river of Poland, which runs into the Dnieſter, 8 miles S. of Kaminiec.

SMRDOW, a town of Bohemia, in the circle of Czaſlau; 9 miles S. of Czaſlau.

SMUGGLING, a cant term for the running of goods, or the offence of importing them without paying the duties impoſed thereon by the laws of the *cuſtoms* and *exciſe*. See each of theſe articles.

This is reſtrained by a great variety of ſtatutes, which inflict pecuniary penalties, and ſeizure of the goods, for clandeſtine ſmuggling; and affix the guilt of felony, with tranſportation for ſeven years, upon more open, daring, and avowed practices: but the laſt of them (19 Geo. II. c. 34.) is for this purpoſe *inſtar omnium*; for it makes all forcible acts of ſmuggling, carried on in defiance of the laws, or even in diſguiſe to evade them, felony without benefit of clergy. For the chief proviſions of this act, which was at firſt temporary, but made perpetual by 43 Geo. III. c. 15, ſee Customs.

SMUSH-POT, amongſt *Painters*, is the veſſel into which they rub off the paint from the pencils, and put the ſcrapings of the pallet.

SMUT, or Ustilago, in *Agriculture*, a diſeaſe in corn, and which, according to M. Duhamel, exhibits the following marks or appearances. 1. This diſtemper deſtroys entirely the germ and ſubſtance of the grain. 2. It affects not only the ear, but alſo, in ſome degree, the whole plant, when it has made a great progreſs. 3. It very ſeldom happens, but that when one ſtalk is ſmutty, all the ears of the other ſtalks from the ſame root are ſo too. 4. So early as in March or April, upon opening carefully the hood or blades which cover the ear, and examining the young ear, then not above the ſixth part of an inch in length; and almoſt cloſe to the roots, he found this embryo already black, and attacked with this diſtemper. Perhaps it may not always ſeize the plant ſo early. 5. When the diſtempered ear comes out of its covering formed by the blades, it looks lank and meagre: the common, and immediate coverings of the grains, are in this caſe ſo very ſlight and thin, that the black powder is ſeen through them: and from this time nothing is found in lieu of grain, but a black powder, which has a fetid ſmell, and no conſiſtency. As this powder, of which the conſtituent particles have but very little cohesion, and of which the coverings are deſtroyed, is eaſily blown off by wind, or waſhed away by rain; the huſbandman, in houſing theſe plants, houſes only ſkeletons of the ears. If any impreſſion of this powder remains, it is eaſily taken off by ſifting; but he has not experienced it to be contagious, like that of burnt grain. And Mr. Tillet, it is remarked, has obſerved that theſe corrupted ears are often found to be vitiated even in the hood, though this laſt looks as green and perfect as if nothing ailed the corn within. The upper part of the ſtalk of a ſmutty plant is not commonly quite ſtraight, from within about half an inch below the ear. If ſuch a ſtalk is ſqueezed there, it ſcarcely yields at all to the preſſure. If it be cut aſunder at about a ſixth part, or a quarter of an inch below the ear, it will be found to be almoſt entirely filled with pith, in ſuch a manner that only a very ſmall opening can be perceived in the heart of the ſtalk, inſtead of the large pipe that is in healthy ſtems. He concludes from hence, that the circulation of the juices is obſtructed in the upper part of the ſtalks of ſmutty plants. Bearded wheat is apt to be ſmutty, as well as that which is not bearded; but neither Mr. Tillet nor he ever met with a ſmutty ear of rye.

And in reſpect to the cauſes of ſmut, it is obſerved, that the ſmuttineſs of corn cannot be owing to a want of fecundation, as many have hitherto miſtakenly imagined, ſince it affects and deſtroys the organs of both ſexes, long before the time of that fecundation:—that it cannot be imputed to the ſettling of wet upon the ears, or to fogs, or to a violent impreſſion of the ſun; ſince we have ſeen the ears ſmutty long before they ceaſed to be covered with the blades, which continue green till the diſtemper has made great progreſs:—that the ſame obſervations refute abſolutely the opinion of thoſe who ſuppoſe the cauſe of the ſmut to be in the grains after they are formed, and before they are paſt their milky ſtate:—that the ſmut of corn has been alſo aſcribed to the moiſture of the earth; but we do not ſee more ſmutty plants in the loweſt, and conſequently wetteſt parts of a field, than in the higheſt and moſt dry. Beſides, why ſhould there be a ſingle ſmutty plant in the midſt of numbers of ſound ones? However, as it appears that corn is more frequently attacked with this diſtemper in wet years than when the ſeaſons are dry, too much moiſture may perhaps, without being the immediate cauſe of the ſmut, favour its progreſs more than drought would do.

Some naturaliſts have aſcribed this diſtemper to inſects. Our author, if he is not authoriſed abſolutely to deny this, can at leaſt aſſert, that, after having been of this opinion for ſome time, all his endeavours to eſtabliſh it by facts have proved ineffectual. Some obſervers have indeed ſhewn him different inſects in ſmutty grains; but as he found the very ſame kinds likewiſe in ſound ears, he believes, with Mr. Tillet, that they are not in any manner the cauſe of this diſtemper. We know that the corn-caterpillar devours the mealy ſubſtance of the grain: but it does not occaſion ſmut. Numbers of flies lay their eggs upon theſe ſeeds, and the worms and maggots which proceed from them eat the ſeeds; but this does not occaſion any thing like ſmut. The Rev. Dr. Hales, to ſatisfy himſelf whether the ſmut of corn might not proceed from the ſeeds being bruiſed by the flail, took a number of grains, of different ſizes, and bruiſed them with a hammer. Thus his own experience convinced him that he had conceived a wrong idea of the cauſe of this diſtemper.

Several cultivators have thought that pigeons' dung and that of ſheep render corn ſmutty: but this is a groundleſs notion. We have large pigeon-houſes, the dung of which is ſtrewed upon our wheat-lands; yet we do not find that theſe fields are more affected with ſmut than others. This allegation is, therefore, abſolutely deſtitute of proof. It is added, that Wolfius was of opinion that the ſmut of corn proceeded from a monſtroſity of the embryo; but M. Almen has refuted that ſuppoſition, by ſhewing, that the male flowers of certain kinds of plants are attacked with this diſtemper: now the flowers have not any embryo.

And this laſt philoſopher has judiciouſly obſerved, that the ſmut of corn cannot derive its origin from a defect in the ſap; as all the parts of the plant, except the ear, look healthy, and there are plants whoſe roots are perennial, which appear vigorous, though their ſeeds are ſmutty every year. He is of opinion, that whatever weakens the plant is apt to bring on the ſmut, and inſtances as a proof of this, that it is a frequent cuſtom in his country, to cut rye as ſoon as it ſpindles, for food for their cattle; and that this rye generally produces other ears, which ſeldom contain any but diſtempered grain: to which he adds, that ſeed-corn which had been pricked or run through with a needle, or which is not thoroughly ripe, and that which produces lateral or ſecond ears, is ſubject to the ſmut. And he afterwards, from other trials, ſeems diſpoſed to aſcribe this diſeaſe to mouldineſs.

But in the "Memoirs of the Bath Agricultural Society," it is ſaid to be a diſeaſe that only occurs when the weather is wet, during the period of the flowering of the plants, in which the anthers may burſt and the farina be waſhed way. It is ſuppoſed not to be produced by any infectious material, or the *ova* of inſects that may adhere to the grain, as ſmutty ears and ſound ones are found proceeding from the ſame root; and, in ſome inſtances, both ſmutty and ſound grains to be contained in the ſame ear; ſome of the corns having even one end ſmutty and the other ſound, conſequently to ariſe from the want of due impregnation, from the farina fecundans being faulty or imperfect, and that putrefaction takes place on the death of the corn. And this ſuppoſition is ſupported by the experiments of the Italian philoſopher Spallanzani, who found that the ſeed is produced in the plants long anterior to impregnation, which cannot be performed until the flower is open, and the duſt of the anther fully in a ſtate of maturity. And Dr. Darwin, on theſe principles, conceives, that for want of impregnation, or the vivifying principle, the wheat-corn may putrefy, as is the caſe with addle eggs of oviparous animals. However, the inquiries of other writers ſeem to lead to the opinion that the affection is produced by the attacks of an inſect, and that, though certainly infectious, it may be prevented or cured by the uſe of different kinds of pickles.

Further, a variety of facts and reflections have been offered on this ſubject by Mr. R. Somerville, in the ſecond volume of "Communications to the Board of Agriculture;" who begins by remarking, that ſome years ago, he collected a quantity of ſmutted ears from one field of wheat, in which they were very numerous, and a number of healthy well-filled ears from another field, in which there was no ſmut. The grains were rubbed out of both, intimately mixed, and kept in a box for two months, at the end of which time they were rubbed between the hands in ſuch a manner as to break the whole of the ſmut-ball. The parcel was then divided into two equal parts, one of which was three or four times waſhed with pure water, and well rubbed between the hands at each waſhing, and afterwards ſown in a drill in his garden; the other half was ſown in another drill without any waſhing or preparation whatever, the ſoil and every other circumſtance being equal. Both parcels vegetated at the ſame time, and for about two months thereafter there was no viſible difference in their appearance; about that period, he however obſerved, that many of the plants in the drill that had been ſown without being waſhed, were of a darker colour than the others; theſe, when narrowly examined, were of a dirty-green. The plants in the drill that had been waſhed were all of one colour, and ſeemingly healthy; as the ſeaſon advanced, the difference in colour became more ſtriking, and continued to increaſe till the grain was fairly out of the blade: about this time many of the dirty-green ears began to exhibit ſymptoms of decay. As ſoon as the ear was fairly ſhot out, the whole of thoſe in the unwaſhed drill, that had the dirty-green appearance above deſcribed, were found to contain nothing but ſmut; and theſe ſmutted ears were in the proportion of more than ſix to one of the healthy ones; while, on the contrary, the drill in which the waſhed grains had been ſown, and which conſiſted of ſeveral hundred grains, had hardly a ſmutted or unhealthy ear in it. The ſame experiment was repeated the following ſeaſon, and with nearly the ſame reſult. Satisfied with knowing that complete waſhing would be found a remedy for the diſeaſe, he made no farther inquiry upon the ſubject till laſt autumn, when he was employed in making obſervations upon the blight, in the courſe of which he met with a good deal of ſmut in many fields; and being at the time poſſeſſed of ſome excellent glaſſes, he carefully examined ſome of the ſmutted plants. This at firſt was done more as a matter of amuſement, than from any expectation of diſcovering any thing that might contribute to throw light upon the ſubject. Upon a near inſpection with the glaſs, he found that the dirty-green colour of the blades of the ſmutted ears was owing to a number of ſpots infinitely ſmall, and bearing a near reſemblance to thoſe upon blighted ears: his obſervations were continued throughout the whole period of the ripening, in the courſe of which he made no additional diſcovery, except obſerving, that the leaves and ſtalks of the ſmutted ears decayed ſooner than ſuch as were healthy. About the end of autumn, however, having one day brought home ſome ſmutted ears of rather an unuſual appearance, he examined them very narrowly, and obſerved that the balls were perforated in many places with ſmall round holes, a thing he had not before obſerved in any that he had met with: this he aſcribed to vermin; and upon ſticking one of the grains upon a pin, and placing it under the glaſs in a very bright ſun, he could diſtinctly obſerve ſeveral ſmall tranſparent ſpecks upon the beard, or downy part of it. He examined ſeveral more, and met with exactly the ſame appearance; but upon being called haſtily away upon buſineſs, he was under the neceſſity of leaving them upon the table, without being able to aſcertain whether the objects he had ſeen were eggs or inſects. In the evening, when he came home, he reſumed the inveſtigation by *candle-light;* in the courſe of which, as he was under the neceſſity of holding them very near the candle, the heat ſoon relieved him from his embarraſſment, by putting them in motion, and he then diſcovered that the ſpecks above-mentioned were real inſects, reſembling wood-lice in ſhape. Next day he repeated the ſame trials by ſun-light with new ſmut-balls, and diſcovered the ſame appearances, but without being able to make any of the inſects ſtir. Diſappointed and vexed at not being able to ſee them in motion with the ſun-light, and recollecting the heat of the candle, he threw the concentrated rays of the ſun upon them with a burning-glaſs, which completely anſwered his purpoſe of putting them in motion, and ſhewing them in every different point of view. To deſcribe minutely an inſect ſo ſmall as not to be diſtinguiſhable by the naked eye, would, he thinks, be no eaſy matter; it is ſufficient to ſay, that its general appearance is very ſimilar to the wood-louſe, though infinitely ſmaller. As ſoon as he had clearly aſcertained the exiſtence of this inſect, his mind was perfectly at eaſe with regard to the cauſe of the diſtemper; but though he could very readily conceive that vermin, in the early ſtages of the growth of a plant, might ſo injure the ſtamina as to render it unfit to produce any thing but ſmut, he could not ſo well underſtand how it was poſſible for the mere touch of the black earth contained in the ſmut-balls to produce the ſame effect. It is well known, that in the animal body, certain infections are communicated merely by the contact of the ſound and unſound parts; but that in every inſtance where this happens, the injury can be diſtinctly traced to an abſorption of the virulent matter, by the veſſels of the healthy ſubject.

And we are now, he thinks, ſo well acquainted with vegetation, as to know that plants have a circulating ſyſtem as well as animals; and that while they are in a growing ſtate, poiſon as well as nouriſhment may enter their veſſels, and do infinite miſchief. If this reaſoning is ſanctioned by experience, and there can be no doubt of it, and if there is the ſlighteſt analogy between animal and vegetable life, it will at once appear, that no bad effect could poſſibly ariſe from ſmutted and healthy ears coming in contact, either in the ſtack or the barn, as at that time they are in a ſtate of reſt, and no circulation going on. It may be argued in anſwer to this, that while the plants are green, the ſhaking of the wind may bring the ſmutted and the healthy ears into contact, and that the acrimony of the ſmut may corrode and deſtroy the healthy wheat, ſo as to produce the diſeaſe. This idea he knows is entertained by many very good farmers: it is, however, clearly diſproved by the experiment above recited, by which it appears that a ſimple waſhing in water, provided it is properly performed, is a very effectual cure for the diſtemper: common ſenſe will inform us, that had the ſtamina, or germ of the grains ſo waſhed, been injured by any thing of a corroſive nature, even in the ſlighteſt degree, no ablution whatever could poſſibly have repaired the miſchief. And the ſame reaſoning, he ſuppoſes, applies with equal juſtice to the other cauſes aſſigned, with the ſingle exception of inſects; for if either the grain was naturally weak, or had been ſprung in harveſt, or was deficient in its male organs, as is ridiculouſly ſuppoſed, nothing but the higheſt degree of weakneſs and credulity could make any perſon believe, that either the waſhing with water, or indeed any other preparation, could cure ſuch defects.

It is, therefore, his opinion, that the ſmut is occaſioned by the ſmall inſect above deſcribed, as ſeen by the glaſs in the downy part of the grain; and that when the balls are either broken in the operation of thraſhing, or come in contact with clean healthy grains, the inſects leave the ſmutted grains, and, adhering to ſuch as are healthy, are ſown with them, and wound the tender ſtem in ſuch a manner as to render the plant incapable of producing any thing but ſmut. It is not an eaſy matter to account for the manner in which this takes place; but a little attention to the circumſtances he is now to mention will perhaps throw ſome light upon it. It is known that plants of very oppoſite natures and qualities will grow and produce abundantly upon the ſame ſoil, where the nouriſhment is ſeemingly the ſame. This effect is alſo known to be owing to the ſtructure of their veſſels, by the action of which the juices that circulate through them are differently prepared in every different plant. From this ſtriking difference, owing confeſſedly to organization, is it not, he aſks, preſumable that the ſmut in wheat is produced by the inſects wounding the veſſels of the plant in ſuch a manner as to render them incapable of taking up any other principle from the ſoil, but the ſmut contained in the balls, which, upon examination, ſeems to have no quality different from the fineſt vegetable earth? This opinion, he thinks, is ſtrongly ſupported from the circumſtance of certain pickles being found a cure for the malady. The effect of theſe pickles is, however, completely miſunderſtood; for, in place of ſuppoſing, as is erroneouſly done, that they operate by ſtrengthening the grain, and thereby removing that debility which has been long conſidered the cauſe of ſmut, their benefit depends upon the powers they poſſeſs of deſtroying the inſects above deſcribed: but to ſhew the abſurdity of the commonly received opinion in a more ſtriking point of view, it is only neceſſary, he adds, to ſtate, that many of theſe preparations, which are ſuppoſed to be ſo friendly to vegetation, are in fact inimical to it, unleſs they are uſed with the utmoſt caution; even ſtale urine, which has long been conſidered as a ſafe and innocent remedy, is, under certain circumſtances, highly pernicious. After he had diſcovered the inſect, he made trial of all the ſubſtances commonly uſed, and found all of them, when properly applied, deſtructive to it. Is it not, therefore, he contends, more agreeable to plain common ſenſe to ſuppoſe, that the virtue of theſe preparations conſiſts more in the power they have of deſtroying vermin, than in any ſtrengthening quality they poſſeſs?

The following opinion has been offered on this vegetable

table affection by ſir John Call, who ſuppoſes, that the ſmut is occaſioned by certain animalcula depoſited in the huſks of the ear, when the wheat is in bloſſom, which are fed and brought to perfection by devouring the milky juice, and obſerves, that were the diſeaſe radical in the original grain of the ſeed-wheat, or infectious from the juice ariſing through the pores and tubes of the ſtalk, there could not be in the ſame ear, grains, ſome decayed and others quite perfect. But to bring the matter to the teſt of experiment, he collected a quantity of ſmutted ears of wheat, in ſome of which were two or more grains apparently perfect, all which he cauſed to be rubbed out with the hand in a bag, ſmut and altogether; the freſh grains found in the bag were then ſown in a particular ridge amongſt other wheat, in a field under tillage. Their growth from the firſt was ſimilar to the reſt of the wheat; and from a certificate of reſpectable farmers, it appears their produce was as free from ſmut, as that of the field in general. And hence the concluſion is drawn, that waſhing or pickling wheat, as a remedy againſt the ſmut, is unneceſſary and uſeleſs; and that as blights and other diſeaſes of plants are more prevalent from circumſtances in ſome ſeaſons than in others, ſo the ſmut is an accident of a like nature, which mankind can neither foreſee nor prevent. The general experience of farmers is, however, in oppoſition to this ſuppoſition. And whether this vegetable diſeaſe may be produced by inſects, or be the effect of ſome other cauſe, to many of which it has been aſcribed by different philoſophical inquirers; the moſt general practice of farmers has been that of preparing their ſeed by the means of ſome ſort of waſhing or brining. The following is a tabular view of the reſults of trials made with different ſteeps, in order to aſcertain their utility in this intention, as well as in promoting the growth of the grain, as given by Mr. Bevan, in the 9th volume of the "Agricultural Magazine." It contains twelve ſamples of ſmutty wheat, and the ſame number of ſound good wheat, ſteeped in twelve different ſolutions of the moſt common acids and alkalies, and ſalts, moſt readily procured. The wheat was ſown at Leighton, Bedfordſhire, on a ſandy ſoil. The ſolutions were all made cold, and the ſamples continued about twenty-four hours in ſteep. The columns marked A are the reſults from the good wheat, and thoſe marked B are from the ſmutty ſamples. It may be obſerved, that neither of the ſamples ſteeped in the ſolutions of nitric acid came up, excepting a ſingle corn in the good ſample, and which produced above 1200 corns from it.

But M. de Lignerolle contends, that the ſureſt means of avoiding ſmut, and that which he has long practiſed with ſucceſs on upwards of three hundred acres of land, is to change the ſeed every year, to be very careful that the ſeed-corn be well dried and thoroughly ripe, and that it be not ſmutty, nor have any ſmutty powder ſticking to it. He then pours boiling-water on quick-lime, in a large tub; and after the ebullition is over, as much cold water as there was hot, and ſtirs it all ſtrongly together, in order to diſſolve and thoroughly mix the lime. The quantity of wheat intended to be ſowed is ſprinkled with this ley, and then well ſtirred with a ſhovel, and laid in as high a heap as poſſible. It is beſt, he ſuppoſes, to keep the grain for a week after this preparation, turning it every day; for otherwiſe it would heat ſo as to deſtroy the germ. By theſe means he has not had any ſmut, when the fields around him have been infected with that diſtemper. And Mr. Donat, near Rochelle, has uſed the following with ſucceſs: take quick-lime and pigeons'-dung, of each twenty-five pounds, forty pounds of wood-aſhes, and twenty-five pounds of ſea-ſalt, or ſaltpetre. Put all theſe into a tub large enough to hold half a hogſhead of common water, which ſhould be added to them. Stir them all well with a ſtick, till the lime is quite diſſolved. This ley will keep ſome time without ſpoiling. It muſt be ſtirred juſt before the corn is ſteeped in it. The grain is then put into a baſket, and plunged into the ley, where it remains till it has thoroughly imbibed it; after which it is taken out, and laid in a heap till it is quite drained of all its moiſture: or, which is a ſtill better way, take a maſhing-tub, fill it with grain to within four inches of the brim, and then pour in the ley well ſtirred before-hand. When the tub is full, let the ley run out at the bottom into ſome other veſſel, in order to uſe it again for more corn. Let the grain be then taken out and laid in a heap to drain; and continue in this manner to ſteep all the ſeed-corn. The wheat, thus prepared, may be ſowed the next day, and muſt not be kept above five or ſix days, for fear of its heating. This quantity of ley will ſerve to prepare more than twenty buſhels of wheat. Mr. Tull has alſo long ſince obſerved, that brining and changing the ſeed are the general remedies for ſmut. Likewiſe a very intelligent writer in the eleventh volume of the Agricultural Magazine ſays, that he can truly ſtate, that in the courſe of long and extenſive practice, he has never diſcovered the produce of any good and properly prepared ſeed-wheat ſmutted, while that of his unprepared eſcaped. On the contrary, whenever he has ſown any in the latter ſtate, he has always obſerved much ſmut in the crops raiſed from it; and refers his readers to the following account of an accurate comparative ſtatement. On the 15th of March laſt he ſowed two contiguous ridges (in the middle of a very large field,) equal in ſoil, condition, and expoſure, with wheat of the ſame variety, raiſed on the ſame kind of ſoil, in preciſely the ſame mode of management, and thoroughly *mixed*. The ſeed contained a very ſmall quantity of ſmut, perhaps one black ball to a quart; but the other grains were not at all diſcoloured. The ridges were ſet out in an eaſt and weſt direction, each eighty yards long and nine broad. On the weſt half of the northern ridge he ſowed the ſeed without any preparation whatever; and on the eaſt, after being well waſhed in clean river-water. On the weſt half of the other ridge the wheat was ſown after having been wet with old chamber-ley; and on the eaſt half, after being prepared (provincially pickled) in the uſual manner, with old chamber-ley and lime in fine powder. All the land was ploughed and ſown broad-caſt on the ſame day, without any variation of weather, and equally well harrowed. We had a calm, dry, and tolerably warm blooming ſeaſon. Some time after the ears were out he examined the crop very minutely. That after the unprepared ſeed, the waſhed ſeed, and the wheat wet with chamber-ley, contained a great, and that from the ſeed which received the chamber-ley and lime, a very ſmall, quantity of ſmut. The ſtraw of this appeared as good as that of the ſound wheat. Upon every piece of ground he found ears partly ſmutted and partly ſound. In part of theſe ears he found ſome rows of grain containing ſound wheat near the middle of the row, and ſmut both above and below it. With a view of finding the proportion (at harveſt) with ſome degree of preciſion, he took four ſheaves from the middle of the crop raiſed from the pickled ſeed, mixed them thoroughly, reduced them to an equal ſize, *viz.* to the circumference of twenty-four inches, and then carefully picked out and counted the number of ſmutted ears they contained. He purſued preciſely the ſame mode with the crops upon the other pieces of ground, and the reſults were as under:

	Smutted Ears.
The four ſheaves after the pickled ſeed contained -	165
The four do. from the ſeed which was waſhed in clean water - - - - - -	1212
The four do. from the ſeed wet with chamber-ley	723
The four do. from the ſeed which received no waſhing or preparation - - - - -	1270

It is ſuppoſed that it is ſtated in ſome of our agricultural publications, that one of the ſtrong acids, much diluted with water, has been ſucceſsfully uſed in preparing ſeed-wheat, with a view of preventing ſmut; a diſeaſe which has been improperly confounded with blight or mildew. The latter remedy he never tried; he has, however, on ſeveral occaſions, uſed ſea-water (ſo ſtrongly impregnated with ſalt, that an egg would ſwim on it) and lime, and alſo the drainings of fold-yards and lime, and is of opinion that theſe mixtures are not nearly ſo efficacious as the latter article and ſtrong chamber-ley. The beſt mode of preparation is, he thinks, to immerſe the wheat in the chamber-ley, ſtirring it well (about five or ten minutes), and ſkimming off the light grains, &c. The chamber-ley ſhould be let out by a tap, and the wheat ſpread on a floor, and ſo well mixed with the lime that every grain may receive a part of it. If this mode be carefully practiſed with ſeed free from ſmut, he can, from experience, aſſure the huſbandman that he will never ſuffer, in any conſiderable degree, from that diſeaſe. As the lime and chamber-ley will ſoon deſtroy the vegetative principle of the grain, if it be ſuffered to remain in a heap, or in bags, it ſhould be committed to the ground within ſix or eight hours after it has been thus prepared. He has ſometimes known it conſiderably injured after being kept twenty-four hours thinly ſpread out upon a well aired floor. And as, when the ſeed is in a very moiſt ſtate, it will not paſs regularly through the drill-machine, it is neceſſary on that account to have it drier in the drill than the broad-caſt huſbandry.

When the wheat uſed in the above experiment was prepared, a proper veſſel was not at hand, and therefore the chamber-ley was ſprinkled upon it. This, however, is not a good method, for we loſe the chamber-ley, and the advantage of ſkimming off the light grains, black balls, &c.; and notwithſtanding frequent turnings, it ſometimes happens that *all* the grains do not receive a ſufficient quantity of the liquid. A proper veſſel ſhould therefore be conſtantly had recourſe to for this purpoſe.

But on the ſuppoſition of this diſeaſed ſtate of grain being produced by an inſect, the following method of kiln-drying has been propoſed in the third volume of the Farmer's Magazine. Let the wheat be laid upon the kiln about three or four inches thick, the kiln being heated middlingly ſtrong with blind coal; the wheat to continue on the kiln for twenty-four hours, but turned frequently. After taking it off the kiln, it muſt be allowed twenty-four hours to cool, during which time it muſt be frequently turned, and then put through the fanners once or twice. After the wheat has lain a few hours on the kiln, and the fire begins to have effect, a great number of very ſmall worms, formerly undiſcovered by the eye, appear on the top of the grain, and are ſoon deſtroyed by the heat. Theſe come from blacked wheat or other corns that could not be ſuſpected to be indifferent; or may lie in, or on good wheat, which worms continuing, (when not thus killed,) might conſume the corn after it is thrown into the earth, thereby checking the growth entirely, or preventing it from having the ſtrength it otherwiſe would have, to bring forth a ſtrong productive ſtalk. It is added, that the firſt farmer in Clackmannanſhire who tried the kiln-drying of wheat, inſtead of pickling it, learnt it about twenty-five years ago (and he has continued the practice ever ſince) from an Iriſhman, who had been appointed by the Board of Truſtees to ſtamp the linens, &c. manufactured in the village of Alva, who aſſerted that it was practiſed in his part of Ireland; but at this diſtance of time, the farmer has forgot what part of Ireland the man ſaid he came from. See Pickle and Steeping.

Further, with the view of cleaning ſmutty grain, various methods have been propoſed; as by agitating it with different ſubſtances, as ſand, and lime made from ſtone, or white or grey chalk, which, when uſed, ſhould be finely ſifted, and then well blended with the wheat in proportion to the ſtate of the ſmut, as from one to two buſhels for a load of five quarters, which ſhould then be paſſed through a machine one or more times, according to the purpoſe for which the wheat is intended. And for common purpoſes, it is ſuppoſed that the ſmut in wheat may be removed by a machine with bruſhes, invented for the purpoſe; but that if it be for ſeed, it ſhould be put in a trough, or wicker receiver, under the ſpout of a pump, or the fall of a ſtream, and be briſkly ſtirred about, until the injurious ſubſtance floats away, or can be ſkimmed off from the ſurface. When intended for flour, after this waſhing, it muſt be dried on a malt-kiln for the ſpace of eighteen hours, but heated ſo as not to exceed 85° of Fahrenheit's thermometer. The repreſentation of a machine contrived for this uſe, may be ſeen in the Corrected Agricultural Report of Berkſhire.

M. Chantran preſented a memoir to the French National Inſtitute in 1799, on the ſmut in wheat, and its acid. After remarking, that ſtalks which bear charred ears do not differ from others, and that theſe ears often contain good and bad grains, he thought himſelf authoriſed to advance, that this diſeaſe does not exiſt, as generally believed, in the germ of the ſeed from which they ſprung. However, he does not conſider liming the ſeed as uſeleſs; he thinks that it deſtroys the animalculæ attached to the ſeeds, and that the reaſon of its not entirely extirpating the ſmut, is becauſe it cannot act on thoſe ſmall inſects which occaſion it, and which happen to be ſcattered in the ground.

Having analyſed forty-ſix grains of ſmut, he found in this ſubſtance an acid eaſy to be demonſtrated. For this purpoſe, boiling water being infuſed over it, gave a ſtrong tinge of red to tincture of turnſole, while the remainder of this tincture retained its former character. Smut, deprived of the acid, and calcined in the open air, emitted the odour of burnt corn, and gave a reſiduum ſix times as large as the ſame quantity of the farina of wheat treated in the ſame manner. This, joined to microſcopic obſervations, ſays Chantran, proves the animal nature of this ſubſtance, and a difference between it and the farina of wheat greater than could ariſe merely from diſeaſe. The acid of ſmut is not volatile, and may be concentrated by diſtillation. With lime and with ammonia it proves an inſoluble ſalt; and this diſtinguiſhes it from the phoſphoric acid. Combined with potaſh it gave a ſalt cryſtallized in ſmall deliqueſcent needles of a bitter taſte. It decompoſes carbonate of lime.

SMUT, or *Blacks*, in oats, a ſort of vegetable diſeaſe that often occurs or takes place in crops of this kind, in much the ſame manner as that of ſmut in wheat, in many of the country diſtricts. It is ſaid by ſome to affect the whole of the ear of the grain, being occaſionally met with in different ſtages of its progreſs in the ſtanding crops, as well as at the time of threſhing out the corn, as in thoſe of a ſoft unctuous ſtate, in the ſtate of a ball, and in a powdery ſtate, or that of a fine duſt, which diſperſes itſelf in threſhing, and fixes upon different parts of the faces of the men who threſh, rendering them quite black. But others, probably without ſufficient obſervation or knowledge of the fact, ſuppoſe it to be a plant growing ſeparately among the oats.

It is an affection of this ſort of grain which happens frequently on the eaſtern ſide of the county of Lancaſter, in the Iſle of Man, and in ſeveral other ſituations. It is found to prevail leſs among the potatoe oat crops than thoſe of any other ſorts of that grain, and to be much more prevalent in ſome years than in others.

No effectual method of preventing it has yet been diſcovered, but it is found to be much leſſened by the good cultivation and management of the land on which this ſort of crop is grown. The oat crops, where it exiſts to any conſiderable extent, are much leſs productive than in other circumſtances, and the quality of the produce is probably not ſo good. But the diſeaſed ſubſtance is ſo light in its nature, that it is readily blown away in dreſſing or cleaning the grain without its doing much miſchief to it.

SMUT-*Balls*, the ſmall balls of ſmutty matter which are found among diſeaſed wheat and other crops. Theſe balls, as well as the diſeaſed parts of the crops, appear now, from actual experience, to be conſtantly of a very infectious nature, and ſhould, of courſe, be as much guarded againſt, and cautiouſly avoided, in preparing the ſeed of the crops for ſowing, as poſſible; as it is not improbable, but that the diſeaſe may ſometimes be communicated and propagated in this way, without the farmer being in the leaſt aware of it. See STEEPING *Seed-Grains and Seeds*.

SMYNHUSEN, in *Geography*, a town of the duchy of Holſtein; 6 miles E. of Lunden.

SMYRHIZA, in *Botany*, a name uſed by Pliny, and ſome other old authors, for the common myrrhis, or chervil.

SMYRNA, in *Ancient Geography*, one of the Ionian towns of Aſia Minor, ſituated towards the northern part of the iſthmus of the peninſula of Colophon, upon a gulf bearing the name of the town. This town is very ancient, and is ſaid to have been founded by the Smyrnæans, who inhabited a quarter of Epheſus called "Smyrna," from whom it derived this name. Being expelled by the Æolians, they retired to Colophon; but the Colophonians having been obliged to expatriate themſelves on account of ſedition, found an aſylum among the inhabitants of Smyrna. Some time afterwards, finding that the Smyrnæans celebrated without their city a feaſt in honour of Bacchus, they ſhut the gates and took poſſeſſion of the town. The Æolians came to their ſuccour; but it was at length determined, by common conſent, that they ſhould leave the Ionians in poſſeſſion of the town, and withdraw themſelves with all their moveable effects. The Smyrnæans having accepted this condition, they diſtributed themſelves into eleven other Æolian cities, where they obtained the right of citizenſhip. At a ſubſequent period the Lydians took poſſeſſion of Smyrna under Ardys; and having deſtroyed it, the inhabitants diſperſed themſelves into different diſtricts. Four hundred years afterwards, Alexander rebuilt it about twenty ſtadia from its ancient ſcite. Strabo, however, attributes its re-eſtabliſhment to Antigonus and Lyſimachus, without mentioning Alexander. Nor does Arrian, in his hiſtory of this province, take notice of this circumſtance. Hence it is natural to conclude, that Alexander only formed a deſign of rebuilding it, or that he partially executed his project; that it was continued by Antigonus, and completed by Lyſimachus. This town was deſtroyed by an earthquake A.D. 180, according to Euſebius, but according to Dion Caſſius, two or three years ſooner. The Chronicon Paſcale dates it A.D. 178. Marcus Aurelius re-eſtabliſhed it. The river Meles ran by its walls, and near its ſource was another, where it has been ſaid that Homer wrote his poems. Hence it was that Tibullus (l. iv. c. 1.) called theſe poems "Meletere Carmen," but Smyrna arrogates to itſelf the honour of having given birth to Homer. At Smyrna there was a quadrangular portico, with a temple of Homer and his ſtatue. The Smyrnæans had alſo a bronze coin, which they called "Homerium." This town was built partly on the brow of a hill and partly on a plain; and towards its front and the gymnaſium was the temple of the Mother of the Gods. The ſtreets were paved, and interſected one another at right angles. It had ſeveral grand porticoes of a ſquare form, ranges of buildings, and a fine library. In proceſs of time Smyrna became the centre of the commerce of Aſia. Luxury drew hither the arts; and it was decorated by ſuperb edifices, and crowded by a multitude of ſtrangers. At Smyrna there were none of thoſe tyrants who oppreſſed many other cities of Aſia, and even the Romans reſpected the happy ſtate of this town, and left it the ſhadow of liberty. This city has retained a very conſiderable degree of its ancient celebrity. See the next article.

SMYRNA, or *Iſmir*, in *Geography*, a city and ſea-port of

Aſiatic Turkey, in the province of Natolia, ſituated on a gulf of the Mediterranean, which is capable of containing the largeſt navy in the world. On account of the extent and convenience of its harbour, it is become the common rendezvous of merchants from the four parts of the world, and the ſtaple of their commerce ; ſo that it is the firſt port for trade in the Turkiſh dominions. Its ſituation is delightful ; and approaching it by ſea, it has the appearance of a capacious amphitheatre, crowned at the ſummits with the ruins of an ancient caſtle. The bay is extenſive, the anchorage excellent, and the water ſo deep, that ſhips of conſiderable burden may anchor cloſe by the wharf. Many Engliſh merchants reſide here, and they have a conſul to protect them. The trade is conducted by Jew brokers, who are wealthy, and live handſomely and even ſplendidly. The whole town is a continual bazar, or fair, abounding with every thing that ſerves for clothing, ſuſtenance, and pleaſure ; all the beſt commodities of Europe and Aſia being brought hither for ſale.

The adjacent territory is very fertile, abounding with fine olive-trees and vines ; and it affords excellent wine. The European conſul lives here in great ſtate and magnificence. The population of Smyrna conſiſts of about 130,000 perſons : of theſe, about 70,000 are Turks, 30,000 Greeks, 15,000 Armenians, 10,000 Jews, and 5000 ſtrangers and Franks. The governor is appointed by the Porte, who manages the civil concerns in the city ; but in all criminal caſes is ſubject to the mollah or cadi, who is judge of his diſtrict. The ſalary of the governor, or muſelim, is eſtimated at nearly 300,000 piaſtres, or about 17,000*l.* ſterling.

In the environs are ſeveral fine villages, to which the Franks and wealthy inhabitants reſort in ſummer, particularly Bournabat, at the diſtance of about half an hour's ride, ſtanding on the banks of the Melica, and at the foot of ſeveral mountains. Other villages are Cucklueiah, where the imperial conſul has a palace ; Bugiah, where the Britiſh conſul has a good houſe ; and Sadig, where the Dutch conſul reſides.

The total value of goods from Smyrna to London amounted, on an average of the years 1785, 1786, and 1787, to 463,349*l.* ſterling, and from London to Smyrna to 423,548*l.* In 1790, 1791, and 1792, the exports to London amounted to 779,610*l.*, and the imports from thence to 848,240*l.* This city ſuffered very much by a fire on the 6th of Auguſt, 1763, which deſtroyed many of the beſt houſes, factories, and magazines, and occaſioned very extenſive deſolation. The loſs ſuſtained was reckoned at 200,000*l.* ſterling ; 176 miles S.S.W. of Conſtantinople. N. lat. 38° 28′. E. long. 27° 8′.

SMYRNA, a poſt-townſhip of America, in the ſtate of New York, and county of Chenango ; 105 miles W. of Albany, bounded N. by Lebanon in Madiſon county, E. by Sherburne, S. by Plymouth, and W. by German. It is ſix miles ſquare, and its ſtreams ſupply grain-mills, ſaw-mills, and a fulling-mill. It has alſo a ſmall furnace for caſting of iron. Its vallies are rich and productive, and a great part of the hilly land is either arable, fit for meadow, or good for grazing. Hemp is cultivated on the rich mould of the vallies, and the timber is principally maple, beech, elm, baſs-wood, and hemlock. The firſt ſettler here was Porter, in 1792, and a poſt-office was eſtabliſhed in 1808. The whole population, in 1810, conſiſted of 1344 perſons.

SMYRNA, *New*, a town of Eaſt Florida, inhabited by a colony of Greeks and Minorquins, eſtabliſhed by Dr. Turnbull, on a branch of the Moſquito river. N. lat. 28°.

SMYRNIUM, in *Botany*, indubitably the σμυρνιον of Dioſcorides, whoſe ample deſcription is peculiarly applicable to one of the ſpecies, *S. perfoliatum.* By his account of the ſenſible qualities of the ſeed, being ſo like Myrrh, the origin of the name from σμυρνα, *myrrh*, is ſufficiently apparent.—Linn. Gen. 144. Schreb. 194. Willd. Sp. Pl. v. 1. 1467. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 328. Prodr. Fl. Græc. Sibth. v. 1. 202. Ait. Hort. Kew. v. 2. 157. Purſh v. 1. 196. Juſſ. 219. Tourn. t. 168. Lamarck Illuſtr. t. 204. Gærtn. t. 22.—Claſs and order, *Pentandria Digynia.* Nat. Ord. *Umbellatæ.*

Gen. Ch. *General umbel* unequal, increaſing daily in ſize ; *partial* erect. *General* as well as *partial involucrum* wanting. *Perianth* ſcarcely diſcernible. *Cor. Univerſal* uniform ; the flowers of the diſk abortive ; *partial* of five lanceolate, keeled, ſlightly inflexed petals. *Stam.* Filaments five, ſimple, the length of the corolla ; anthers ſimple. *Piſt.* Germen inferior, ſtyles two, ſimple ; ſtigmas two, ſimple. *Peric.* Fruit oblong, ſtriated, ſeparable into two parts. *Seeds* two, creſcent-ſhaped, convex on the outer ſide, and marked with three angles ; flat on the other.

Eſſ. Ch. Involucrum neither general nor partial. Fruit oblong, with angular ribs. Petals pointed, keeled, incurved.

1. S. *perfoliatum.* Perfoliate Alexanders. Linn. Sp. Pl. 376. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 289, unpubliſhed. (S. creticum ; Matth. Valgr. v. 2. 131. Ger. Em. 1024. An Hippoſelinum ; Column. Ecphr. v. 2. 21.)—Stem-leaves ſimple, claſping the ſtem with their heart-ſhaped baſe, all ſerrated and alternate.—Native of Italy and the Levant. Common in the hilly parts of Greece, as well as in Crete and Cyprus. *Sibthorp.* A hardy biennial plant, one of the handſomeſt of its tribe, naturalized, in a manner, on rock-work, neglected banks, or open borders, in Chelſea garden, flowering in May. This anſwers moſt preciſely to the σμυρνιον of Dioſcorides, inſomuch that we can only wonder at the doubts of any of his commentators. "Παραφυαδας εχοντα πολλας" ſurely alludes to the abundance of very peculiar leaves *ſurrounding* the ſtem, which are contraſted, in the next ſentence, with the broader foliage, ſpringing from the root. That expreſſion, therefore, is improperly rendered by the word *ſoboles*, offsets or ſcyons, of which there are no traces. The *root* is brown, fleſhy, tuberous, with thick fibres. *Stem* two feet high, much branched, with dilated membranous angles, eſpecially in the branches. *Radical leaves* ſtalked, twice or thrice ternate ; their leaflets ſtalked, ſmooth, ſhining, ovate or wedge-ſhaped, notched, three-cleft, or variouſly lobed ; *ſtem-leaves* ſeſſile, ſimple, roundiſh-heart-ſhaped, crenate, ſmooth, reticulated with veins, either more or leſs obtuſe, or acute and elongated, embracing the ſtem with their broad, rounded baſe, one of whoſe lobes folds over the other ; their colour becomes a rich golden yellow as the *flowers* advance toward perfection ; the upper ones are gradually ſmaller, more coloured, and cloſer together. *Umbels* yellow, of many rays. *Seeds* black, globoſe, angular, ſcarcely ribbed, about the ſize of cabbage ſeed, of a hot, pungent, aromatic flavour, like the reſt of the plant. The *petals* are really heart-ſhaped, with inflexed points.

2. S. *ægyptiacum.* Egyptian Alexanders. Linn. Sp. Pl. 376. Amoen. Acad. v. 4. 270. Willd. n. 2.—Floral leaves oppoſite, heart-ſhaped, entire.—Gathered in Egypt by Haſſelquiſt. Of this there is no figure. By the Linnæan ſpecimen, which conſiſts of the top of the plant only, it appears nearly akin to the preceding ; but differs eſſentially in having the *branches* oppoſite, or three together, not alternate, the *floral leaves* being alſo diſpoſed in the ſame manner, and nearly, if not abſolutely, entire.

3. S. *laterale*. Cape Alexanders. Thunb. Prodr. 51. Willd. n. 3.—Stem-leaves ternate, cut and ſerrated. Umbels lateral, ſeſſile.—Gathered by Thunberg, at the Cape of Good Hope.

4. S. *Oluſatrum*. Common Alexanders. Linn. Sp. Pl. 376. Willd. n. 4. Fl. Brit. n. 1. Engl. Bot. t. 230. (Smyrnium; Matth. Valgr. v. 2. 130. Hipposelinum; Ger. Em. 1019. Petroſelinon Alexandrinum; Trag. Hiſt. 436.) — Stem-leaves ternate, ſtalked, ſerrated. Umbels terminal. — Native of rocks near the ſea, the borders of marſhes, or the neighbourhood of ancient buildings, in Britain, France, Spain, Holland, Cyprus, Greece, and Aſia Minor, flowering in ſpring. The *root* is fleſhy, uſually biennial, but we have obſerved it to live ſeveral years in a ſituation where it could not produce flowers. Whole *plant* ſmooth, light green, ſhining, buſhy, three feet high, of an aromatic and ſweetiſh flavour. *Stem* round, pale, furrowed, hollow. Lower *leaves* thrice ternate, with broad, deeply ſerrated, variouſly ſhaped leaflets, ovate or wedge-ſhaped at the baſe. *Footſtalks* dilated, concave, ribbed, and membranous. *Umbels* numerous, greeniſh-white, globoſe, of many general and partial rays; very rarely accompanied by a few ſmall, awlſhaped leaves of a *general involucrum*, but this is accidental, and occurs now and then in other genera that, like this plant, have never any *partial involucrum*. The *fruit* is black, compoſed of two aromatic, acrid, bitter, three-ribbed *ſeeds*, as big as thoſe of the garden *Tropæolum*, or Naſturtium. There can be no more doubt of this being the ιπποσελινον of Dioſcorides, than there is reſpecting his ſynonym for our firſt ſpecies. The old name of *Olus atrum*, or Black Pot-herb, probably alludes to the colour of the ſeeds, which are remarkably large and conſpicuous. Our Engliſh one was perhaps introduced from Germany, where, as well as in Italy, Ray ſays the plant is called *Herba Alexandrina*. Were it not for this information, we might ſuſpect Alexanders, or Aliſanders, (as the word ſometimes is written,) to be a corruption of *Oluſatrum* pronounced with a broad foreign twang. The root and young herbage formerly ſerved thoſe purpoſes in ſallads and broths, which are now better anſwered by the more delicately flavoured Celery.

5. S. *apiifolium*. Smallage-leaved Alexanders. Willd. n. 5. Ait. n. 3. (S. creticum, paludapii folio; Tourn. Cor. 22.) — "Stem-leaves wedge-ſhaped, obtuſe, three-cleft, toothed."—Gathered in Crete, by Tournefort, from one of whoſe ſpecimens, conſiſting of a branch with *umbels* in ſeed, Willdenow adopted this ſpecies. He informs us there was no general or partial *involucrum*. We have ſeen nothing anſwering to the above account.

6. S. *cordatum*. Heart-leaved Alexanders. Walt. Carolin. 114. Purſh n. 1. (Thapſia trifoliata; Linn. Sp. Pl. 366. Willd. Sp. Pl. v. 1. 1465. Ait. Hort. Kew. v. 2. 156. Sium folio infimo cordato, caulinis ternatis, omnibus crenatis; Gron. Virg. 43.) — Radical leaves roundiſh-heart-ſhaped, crenate, ſimple; thoſe of the ſtem ternate, ſtalked, acute, ſerrated. Ribs of the ſeeds prominent, compreſſed.—In woods, frequently on the mountains, from New England to Carolina, flowering in June and July. *Root* perennial. *Flowers* yellow. *Purſh*. The habit of the whole plant, and, if we miſtake not, the character of the ſeeds, both agree with the preſent genus, but not at all with *Thapſia*; yet it is to be wiſhed that Walter, in transferring this ſpecies hither, had not needleſsly changed the ſpecific name. The *herb* is ſmooth, ſlender, erect, ſlightly branched. *Leaves* light-green; the radical ones ſimple, ſhaped like thoſe of a violet, on long ſtalks; the reſt ternate, more ovate and acute. *Umbels* ſmall, denſe, terminal, ſolitary. Walter ſays the *flowers* are white; and ſo they appear rather than yellow, in Kalm's ſpecimen. The *ſeeds* are ſmall, oval, brown, with three prominent, rounded, thick-edged, flat ribs to each.

7. S. *aureum*. Golden Alexanders. Linn. Sp. Pl. 377. Willd. n. 6. Ait. n. 4. (Angelica acadienſis, flore luteo; Dodart Mem. ed. Amſterd. 557. t. 1.)—Leaves twice ternate; the middle diviſion often pinnate; leaflets ovato-lanceolate, ſtrongly ſerrated. Seeds elliptical, furrowed.—On the mountains and hills, near banks of rivers, from Pennſylvania to Carolina, flowering in June and July. *Purſh*. *Root* perennial, black, tufted. *Stems* numerous, erect, hollow, a foot and a half high, angular, furrowed, ſmooth like every other part of the plant, except at the origin of the *footſtalks*. Lower *leaves* on long ſtalks, ſpreading; their *leaflets* an inch or more in length, coarſely ſerrated, acute, but not pointed. *Umbels* ſmall, denſe, yellow. *Seed* brown, not unlike Caraway ſeeds. The whole plant is ſaid by Dodart to be acrid, bitter, and aromatic, "very different in flavour from common Angelica." We have, from the Rev. Dr. Muhlenberg, a variety of this, with much narrower, ſharper, more finely ſerrated *leaflets*.

8. S. *acuminatum*. Pointed-leaved Alexanders. (S. aureum β; Linn. Sp. Pl. 377. Willd. n. 6. S. foliis caulinis decompoſitis acuminatis; Gron. Virg. 44.) — Leaves twice ternate; the middle diviſion pinnate; leaflets ovate, taper-pointed, copiouſly and ſharply ſerrated. Rays of the umbel elongated.—Native of Virginia; ſent by Gronovius to Linnæus, who confounded it improperly with the laſt. The whole plant appears to be much larger. *Stalks* of the radical *leaves* at leaſt a foot long; *leaflets* two inches or more in length, with very numerous, cloſe, acute, rather unequal ſerratures, and taper points; ſtem-leaves ſmaller, leſs compound. *Umbels* ſolitary, on long terminal ſtalks; the general *rays* above an inch long, while in flower, accompanied, in our ſolitary ſpecimen, with a ſerrated acceſſory leaf, which cannot be ſuppoſed a general *involucrum*, though a few of the partial *umbels* are each alſo furniſhed with a ſingle entire lanceolate leaf, more indicative of a partial *involucrum*. The *flowers* ſeem to be yellow. We have no knowledge of the *ſeeds*, and the genus of this plant muſt therefore remain doubtful.

9. S. *atropurpureum*. Dark-purple-flowered Alexanders. Lamarck Dict. v. 3. 667. Purſh n. 3. — "Leaves all ternate; leaflets ovate, acute, ſerrated."—On dry ſlate hills in Virginia and Carolina, flowering from May to July. *Purſh*. *Root* perennial. *Stem* a foot or more in height, ſlightly branched, angular, ſmooth. *Leaflets* ovate, more or leſs elongated, pointed, ſmooth, rather fleſhy, finely and regularly ſerrated, and ſomewhat cartilaginous at the edges, green on both ſides. *Umbels* ſmall, terminal, ſtalked, of a very dark purple; the partial ones having ſometimes a very ſhort *involucrum*. *Deſrouſſeaux* (in Lamarck).

10. S. *integerrimum*. Entire-leaved Virginian Alexanders. Linn. Sp. Pl. 377. Willd. n. 7. Ait. n. 5. Purſh n. 4. — Leaves glaucous, twice or thrice ternate; leaflets oval, entire. Rays of the umbel elongated. Central flowers abortive. Seeds ovate, angular.—On dry hills, from New England to Carolina, but ſcarce; flowering in June. *Root* perennial. *Purſh*. The whole *plant* is ſmooth; and glaucous in ſome degree. *Stem* round, ſomewhat branched, leafy. *Leaflets* about an inch long. Common *footſtalk* of the ſtem-leaves concave, dilated, membranous; partial ones long and ſlender. *Umbels* without any general or partial *involucrum*; the general *rays* long and ſlender: partial ones ſhort. *Flowers* yellowiſh; the central ones

male, or abortive. *Fruit* the ſize of muſtard-ſeed, blackiſh, obſcurely angular in Kalm's dried ſpecimen, agreeing much with ſome kinds of *Liguſticum*, to which genus this plant is cloſely allied in habit; ſee LIGUSTICUM. The *ſeeds* of theſe genera are, in ſome caſes, nearly akin; which circumſtance has led a learned botanical traveller, Marſchall von Bieberſtein, to name a plant of mount Caucaſus *Smyrnium nudicaule*, which is no other than *Liguſticum cornubienſe*, according to a ſpecimen from Dr. Fiſcher. This is the more ſurpriſing, as the ſame able botaniſt had previouſly deſcribed *Danaa* of Allioni, which is the very ſame ſpecies, for a *Pimpinella*. See Sims and Konig's Ann. of Bot. v. 2. 433. The preſence of a general and partial *involucrum*, and eſpecially the ſmall, not capitate, *ſtigmas*, prove it, nevertheleſs, to be no *Pimpinella*; nor do the *ſeeds* themſelves anſwer to that genus.

11. S. *nudicaule*. Naked-ſtalked Alexanders. Purſh n. 5.—"Leaves radical, ternate; leaflets with a few unequal teeth. Flower-ſtalk radical. Rays of the umbel elongated, with ſcarcely any general or partial involucrum."—Gathered by governor Lewis, on the Columbia river, flowering in April and May. *Root* perennial. The natives eat the tops of this plant, and boil it in their ſoups, as we uſe celery. *Purſh.*

SMYRNIUM, in *Gardening*, contains a plant of the herbaceous eſculent kind, of which the ſpecies cultivated is the common alexanders (S. oluſatrum).

Method of Culture.—Theſe plants are raiſed from ſeeds, which ſhould be ſown in the ſpring, in any light ſoil and open ſituation, in ſhallow drills, fifteen or eighteen inches aſunder; and when the plants are come up two or three inches high, be thinned out to ſix or eight inches diſtance in the rows, to give them room to ſhoot up ſtrong; when earth muſt be drawn up about them gradually, in order to blanch or whiten them a little below, that they may be more criſp and tender for autumn and winter uſe; but as in the ſpring following they ſhoot out again vigorouſly, ſome earth ſhould be hoed up cloſe about each plant, and in three or four weeks they will be blanched fit for uſe.

This is uſed as a culinary plant, when blanched, in the ſame manner as celery, and is of a warm aromatic quality.

SMYRUS, in *Ichthyology*, a name ſometimes given by Pliny to the fiſh called by authors *myrus*, the *Muræna myrus* of Linnæus, and by Willughby the *ſea-ſerpent*, with a compreſſed tail.

It is a ſpecies of the muræna according to Artedi, and is diſtinguiſhed from all the others by that author, under the name of the muræna with a ſharp ſnout, variegated with white ſpots, and with the edge of the back-fin black.

SMYTHAM, in *Mineralogy*, lead-ore ſtamped and pounded down, like powder or ſand, to cleanſe the ſtones and earth from the ore.

SNAASEN, in *Geography*, a lake of Norway, in the province of Drontheim, 24 miles long and three wide; 54 miles N.N.E. of Drontheim.

SNACKENBURG, a town of Weſtphalia, in the principality of Luneburg-Zelle; 52 miles E.S.E. of Luneburg.

SNÆFELL's SYSSEL, a diſtrict of Iceland, about ſix miles to the weſt of Miklaholt, which is a village ſituated on a ſmall eminence, completely ſurrounded by moraſſes, and conſiſts of a church, the prieſt's houſe, and a few cottages. This Syſſel forms the extremity of the peninſula, terminated by the Snæfell Jokul. The central part of this peninſula, through its whole length, is occupied by a lofty range of mountains, between which and the ſea, on the ſouthern ſide, an extenſive tract of flat land intervenes. Beyond Miklaholt, this plain narrows conſiderably, becoming not more than three or four miles in width. Some part of this extent is ſandy, and appears to have been left by the ſea. The greateſt part, however, is boggy; and the whole is covered with an abundance of fine graſs, on which numbers of cattle and ſheep are ſeen grazing. Here and there are ſmall elevations. See STADERSTAD.

The height of Snæfell Jokul was aſcertained by calculation to be 4558 feet; which eſtimate differs no more than a few feet from the meaſurement of the Daniſh officers, who at this time (1810) were employed in ſurveying the coaſts of Iceland. Nevertheleſs, Egbert Olaſſoo, one of the moſt eminent naturaliſts in modern times, aſſerts that, by barometrical meaſurement, he found the height of this mountain to be not leſs than 7000 feet; a calculation that certainly differs widely from the truth. This mountain is volcanic, as part of it has diſcharged lava, which has flowed into the ſea: but this lava is very ancient; as no eruptions have taken place, either from the Snæfell Jokul, or from any part of the adjacent mountains, ſince the iſland firſt became inhabited. This mountain was aſcended by the travellers whoſe report we are now citing, and they have deſcribed the progreſs of their aſcent, which was a very adventurous undertaking, on account of the chaſms and precipices occaſioned by the ſnow that covers the ſummit and ſides of it.

Snæfell Syſſel is ſituated on the weſtern coaſt (ſee SYSSEL), and contains 270 farms, 652 families, and 3541 inhabitants. Mackenzie's Travels in Iceland.

SNAFELSNESS, a promontory on the weſt coaſt of Iceland, 45 miles long, and five broad.

SNAFFEN, a town of Norway, in the province of Drontheim; 46 miles N.E. of Drontheim.

SNAFFLE, in the *Manege*, a well-known kind of bridle. The ſnaffle, after the Engliſh faſhion, is a very ſlender bitmouth, without any branches; they are much uſed in England inſtead of true bridles, which are only employed in the ſervice of war. The French call them *bridons*, by way of diſtinction from *brides*, i. e. *bridles*.

The ſnaffle, or ſmall watering-bit, is commonly a ſcatchmouth, accoutred with two little very ſtraight branches, and a curb, and mounted with a head-ſtall, and two long reins of Hungary leather. See BRIDLE.

The ſnaffle is much recommended by Mr. Berenger in his Hiſtory and Art of Horſemanſhip, vol. ii. p. 225, &c.

SNAFIELD, in *Geography*, the higheſt mountain in the Iſle of Man; its height, obſerved by an exact barometer, the mercury of which ſubſided $2\frac{1}{10}$ inches, being about 580 yards. The ſummit of this mountain affords a proſpect of England, Scotland, Ireland, and Wales.

SNAG-GREET. See SNAIL-*Cod*.

SNAIL, in *Ichthyology*. See LIPARIS *Noſtras*.

SNAIL, *Helix*, in *Natural Hiſtory*. See HELIX.

The *garden ſnail*, or *helix lucorum* of Pultney, is a well-known ſpecies: it abounds with a viſcid ſlimy juice, which it readily gives out by boiling to milk or water, ſo as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious ſtate of the humours, in conſumptive caſes and emaciations. See HELIX *Hortenſis*.

The *exotic ſnail*, or *pomatia helix* of Linnæus, is alſo celebrated on account of its naturalization in this country, by ſir Kenelm Digby, and its uſe, as a food, in ſeveral parts of Europe during Lent. See POMATIA and HELIX *Pomatia*.

Perrault doubts of ſnails having eyes, and Dr. Brown denies it; but according to Dr. Porterfield, a good microſcope ſhews them diſtinctly.

The eyes of ſnails are lodged in their horns, one at the end of each horn, which they can retract at pleaſure. Med. Eſſ. Edin. vol. iii. art. 12.

The manner of examining theſe eyes, which are four in number, is this; when the horns are out, cut off nimbly the extremity of one of them, and placing it before the microſcope, you may diſcover the black ſpot at the end to be a really ſemiglobular eye.

The diſſection of this animal is very curious; for by this means the microſcope not only diſcovers the heart beating juſt againſt the round hole near the neck, which ſeems the place of reſpiration, but alſo the liver, ſpleen, ſtomach, and inteſtines, with the veins, arteries, mouth, and teeth, are plainly obſervable; the guts of this creature are green, from its eating of herbs, and are branched all over with fine capillary white veins; the mouth is like a hare's or rabbit's, with four or ſix needle-teeth, reſembling thoſe of leeches, and of a ſubſtance like horn.

Snails are ſaid to couple three times at the diſtance of about fifteen days from each other, nature producing a new ſpear for each time of copulation, which laſts ten or twelve hours; at the end of about eighteen days they bring forth their eggs, by the aperture of their neck. Baker's Microſcope, p. 217. Mem. Roy. Ac. Abr. vol. iii. p. 85.

So ſmall an animal as the ſnail is not free from the plague of ſupporting other ſmall animals on its body; and as in other animals we find theſe ſecondary ones either living only on their ſurface, as lice, &c. or only in the inteſtines, as worms; it is very remarkable that this creature infeſts the ſnail in both theſe manners, being found ſometimes on the ſurface of its body; and ſometimes within its inteſtines.

There is a part of the common garden ſnail, and of other of the like kinds, commonly called the *collar;* this ſurrounds the neck of the ſnail, and is conſiderably thick, being the only part that is viſible when the animal is retired quietly into its ſhell. In this ſtate of the animal, theſe inſects, which infeſt it, are uſually ſeen in conſiderable numbers, marching about very nimbly on this part: beſides, the ſnail, every time it has occaſion to open its anus, gives them a place by which to enter into its inteſtines, and they often ſeize the opportunity. Mem. Roy. Ac. Abr. vol. iii. p. 377, &c.

Snails are great deſtroyers of fruit in our gardens, eſpecially the better ſorts of wall-fruit. Lime and aſhes ſprinkled on the ground where they moſt reſort, will drive them away, and deſtroy the young brood of them: it is a common practice to pull off the fruit they have bitten, but this ſhould never be done, for they will eat no other till they have wholly eat up this, if it be left for them.

Ariſtotle and the old Greeks had no idea of the generation of theſe inſects in the manner of other animals, but ſuppoſed them produced ſpontaneouſly; but the Romans ſhew, by many paſſages in their writings, that they have got over this error; and even ſeem, by the preference they gave to the neck of this animal in this intention, to have underſtood the hermaphrodite ſtructure of this inſect, which much later ages have pretended to make a new diſcovery.

The eaſtern nations at preſent run much into the opinions of the Romans of old, as to provocatives; they uſe, as the others did, every thing that ſerves to the purpoſes of generation in other animals, and every thing that has but the reſemblance of the external figure of the parts ſubſervient to it.

Snail, *Ear.* See Shells.

Snail, *Naked, Limax.* See Slug and Limax.

Snail, *Oat,* a name given by Dr. Liſter, in the Philoſophical Tranſactions, to a ſmall ſnail, which he obſerved under the looſe bark of old willows, elms, and other trees, and which is of a very ſingular ſtructure; the ſhell reſembling an oat-corn, whence the name, and its volutæ, or wreaths, running contrary to the direction of them in other ſnails, that is, eaſt and weſt, as the philoſophers expreſs it, referring it to the motion of the ſun; but theſe ſhells, to uſe that language, have the turns weſt and eaſt, or more plainly, they have the turns running from the right hand to the left, not from the left to the right, as other ſnails. Phil. Tranſ. N° 250.

Snail is alſo the name of the animal inhabiting many kinds of ſhells, as the patella, cochlea, nerite, buccinum, turbo, trochus, voluta, murex, purpura, lyra, and concha Veneris. See Patella, Cochlea, &c.

Snail-*Cod,* in *Agriculture,* a name given by Mr. Worlidge to a ſpecies of manure found at the bottom of deep rivers. It is a kind of mud or ſludge, very ſoft, full of wrinkles, and intermixed with many little ſhells and ſnails, to which it is thought to owe a great part of its richneſs. It is ſometimes called *ſnag-greet.*

Snail-*Flower,* in *Botany.* See Phaseolus.

Snail-*Horned,* in *Rural Economy,* a term applied to the horns of ſuch cattle as have them ſhort and down-hanging, with blunt points, and ſomewhat bent, in the common form of the ſnail.

Snail-*Shell, Medic* or *Trefoil,* in *Agriculture,* a plant of the artificial graſs kind, often known by the name of heart clover or trefoil. It was introduced into Berkſhire, according to the agricultural report of that diſtrict, by captain Vancouver, on his return from his voyage round the world, though a native of that country, under the notion of the ſeeds being thoſe of ſome more important plant from the South Sea iſlands. It has ſince been cultivated there, it is ſaid, with ſucceſs, producing a luxuriant herbage, of which cattle are extremely fond. It ſtands the winter well, and a crop may at any time be produced. It is aſſerted to have the advantage of lucerne, in not being eaſily choaked, and in growing on a light ſoil, though it without doubt produces the moſt abundantly in good ſoils. The cultivators have hitherto ſown it in the broad-caſt method, and are, it is ſaid, determined to perſevere, having now collected a ſufficient quantity of its ſeed to enable them to extend their trials to ſome acres of land.

It would ſeem to be deſerving of trials in other counties, where herbage is ſcarce and not eaſily raiſed.

Snail-*Trefoil,* in *Botany.* See Medicago.

SNAITH, in *Geography,* a market-town in a pariſh of the ſame name, lower diviſion of the wapentake of Oſgoldcroſs, liberty of the honor of Pontefract, and Weſt Riding of Yorkſhire, England, is ſituated at the diſtance of 22 miles S. by E. from York, and 174 miles N. by W. from London. The ſcite of this town is a gentle eminence, which riſes from the ſouthern bank of the river Aire, and overlooks a flat and fertile diſtrict of country. The market-day here is Thurſday, weekly; and there are fairs on the firſt Friday in April, 10th of Auguſt, and firſt Friday in September, for horned cattle, ſheep, woollen cloth, linen, and cheeſe. The church is an ancient building, in the pointed ſtyle; remarkable only as the burial-place of the anceſtors of lord viſcount Down, who has a ſeat at Cowick, about a mile S.E. from Snaith. Carlton, two miles to the N.E., is the ſeat of the family of Stapleton, whoſe anceſtors diſtinguiſhed themſelves by their bravery and loyalty during the civil wars between king Charles I. and his parliament.

According to the parliamentary returns of 1811, Snaith pariſh includes eleven townſhips, *viz.* Armin, Baln, Cowick, Goole, Hick, Henſall, Hooke, Follington, Rawcliff, and Snaith, which united contain 1133 houſes, and 5095 inhabitants, of whom about 743 reſide in the town of Snaith. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1812. Carliſle's Topographical Dictionary of England, 4to. 1808.

SNAKE, Anguis, in the Linnæan *Syſtem of Zoology*, is a genus of ſerpents, the characters of which are, that the animals belonging to this genus have abdominal and ſubcaudal ſcales. Here we may obſerve, that Linnæus has diſtinguiſhed the ſmall ſcales, with which the back and ſides of the animals belonging to the claſs of ſerpents are covered, by the name of *ſquamæ;* and the oblong, narrow, tranſverſe plates, with which the bellies of ſome of them are covered, by the denomination of *ſcuta.* Thoſe that have both ſquamæ and ſcuta, he diſtributes under the genus of *coluber;* thoſe that have only ſquamæ, under the appellation of *anguis.* In conformity to this diſtribution, he has ranked the common ſnake, as well as the viper, &c. under the genus of *coluber* (which ſee); and claſſed ſixteen different ſpecies, as the four-footed Javan ſnake, the common ſlow-worm, &c. under that of *anguis.* See Serpentes.

Snake, *Annulated.* See Amphisbæna and Serpentes.

Snake, *Argus.* See Coluber *Argus.*

Snake, *Auſtralaſian.* See Coluber *Auſtralaſiæ.*

Snake, *Black.* See Coluber *Conſtrictor.*

Snake, *Black and Red.* See Coluber *Torquatus.*

Snake, *Blood, Hæmorrhous,* the name of a peculiar ſpecies of ſerpent, ſo called, becauſe it was ſuppoſed, that on a perſon's being bit by it, the blood flowed out of every part of the body.

It is a ſmall ſerpent, ſeldom arriving to more than a foot long; its eyes are remarkably vivid, bright, and ſparkling; its ſkin is very gloſſy, and its back variegated with a great number of black and white ſpots; its neck is very ſlender; its tail extremely ſharp, and it has a ſort of ſmall horns placed over its eyes. It is found in Egypt.

There is alſo an American kind of this, found in the ſouthern parts, and called by the natives *ahucyatli,* which is larger than the other, and reſembles the rattle-ſnake in many particulars, but wants the diſtinguiſhing character in the tail.

Snake, *Boaform.* See Coluber *Boæformis.*

Snake, *Braſilian.* See Coluber.

Snake, *Bull-headed.* See Coluber *Bucephalus.*

Snake, *Coach-whip.* See Coluber *Flagellum.*

Snake, *Common,* or *Ringed, Coluber Natrix* of Linnæus. See Natrix and Coluber *Natrix.*

The following account of an eaſy method of preſerving ſnakes may not be unacceptable. When the ſnake is killed, it muſt be waſhed clean, and put into a glaſs of a proper ſize, the tail firſt, and afterwards the reſt of the body, winding it in ſpiral aſcending circles, and diſpoſing the back, which is always the moſt beautiful, outwardly. A thread connected with a ſmall bead is then, by a needle, to be paſſed through the upper jaw from within outwardly, and then through the cork of the bottle, where it muſt be faſtened: by this means the head will be drawn into a natural poſture, and the mouth kept open by the bead, by which the teeth, &c. will be diſcovered. The glaſs is then to be filled with rum, and the cork ſealed down. In this manner the ſnake may be preſerved for many years; nor will the ſpirits impair or change the luſtre of its colour.

Snake, *Daboya.* See Coluber.

Snake, *Hooded.* See Coluber *Naja.*

Snake, *Horned.* See Cerastes and Coluber *Ceraſtes.*

Snake, *Javan.* See Coluber *Javanicus.*

Snake, *Oak.* See Dryinas and Crotalus.

Snake, *Panther.* See Coluber.

Snake, *Rattle,* a very dreadful genus of ſerpents. See Crotalus.

Snake, *Ruſſelian.* See Coluber *Ruſſelli.*

Snake, *Sand,* the Engliſh name of a kind of ſerpent found in Lybia, and ſome parts of Italy. See Ammodytes.

Snake, *Sea, Serpens Marinus,* the name of a fiſh of the eel-kind, being the cylindric *muræna* (which ſee), with the tail naked and acute, uſually of five or ſix feet in length, and a furrowed body, continuing all the way of the ſame thickneſs, till near the tail. Its back is of a duſky yellow, and its belly a ſhining blue; its ſnout is long, ſlender, and pointed, and the opening of its mouth extremely large; near the end of the under jaw it has four or five large ſharp teeth, which bend backwards; the reſt of the teeth are very ſmall, and ſtand cloſe together; at the very extremity of the upper jaw it has four very large teeth, and all the reſt are ſmall, and like thoſe in the under one; but the largeſt teeth of all are placed in a row, in the middle of the palate; it has only one pair of fins, which are placed near the gills; the opening of the gills is at a conſiderable diſtance from the head, and it is marked with dotted lines down its ſides. It is common in the Mediterranean, and its fleſh is very fine taſted, but full of ſmall bones. Willughby, Hiſt. Piſc. p. 108.

Biſhop Pontopiddan mentions (in his Hiſt. of Norway, vol. ii. p. 195, &c.) a ſea-ſnake of a very prodigious ſize; for the particulars of its dimenſions, &c. we muſt refer to the teſtimonies which he has recorded. Theſe animals, ſome of which are ſaid to be no leſs than ſix hundred feet long, are dangerous to navigators, as they throw themſelves over veſſels of ſome hundred tons burthen, and ſink them to the bottom by their weight. The preſervative againſt them is caſtor, the ſmell of which they are ſaid to avoid. The biſhop apprehends, that this creature, which inhabits the North ſea, is the leviathan mentioned in the ſcripture. Iſaiah, xxvii. 1. Job, xxvi. 13.

Snake, *Sleep.* See Hypnoticus *Serpens.*

Snake, *Spectacle.* See Cobras *de Capello* and Coluber.

Snake, *Triangular-headed.* See Coluber.

Snake-*Gourd,* in *Botany.* See Tricosanthes.

Snake-*Root, Serpentaria,* the root of a ſpecies of ariſtolochia. See Aristolochia *Serpentaria.*

The ancients were only acquainted with two kinds of ſerpentaria, the great and the ſmall: but ſince the diſcovery of America, botaniſts have added ſeveral others; as the ſerpentaria Virginiana, or Virginian ſnake-root; beſides that of Canada, and that of Braſil.

They were ſuppoſed to be alexipharmics, or counterpoiſons; and as ſuch were ingredients in the Venice treacle.

The herb dragon is alſo called, by ſome writers, the great ſerpentaria; by the ancients, dracunculus major. This has its ſtem very ſtraight, ſmooth, and marked with red ſpots, like the ſkin of a ſerpent; whence, probably, as much as from its virtues, it is that it takes its name. Its root is big, round, and white, covered with a thin ſkin. The ſmaller ſerpentaria, of this kind, has its ſtalk much like that of the larger, only its leaves are like thoſe of ivy, whereas thoſe of the larger are digitated, after the manner of baſtard hellebore. Its root is round and bulbous.

The ſerpentaria of Virginia, called alſo colubrina Virginiana, aſarum Virginianum, ſerpentaria nigra, and the contrayerva of Virginia, has its leaves green and large, almoſt in figure of a heart; its fruit round, and its root, which is of a very ſtrong aromatic ſmell, has, at bottom, an infinite number of long ſmall filaments, repreſenting a kind of beard, of a browniſh colour on the outſide, and paler or yellowiſh within.

It was firſt brought into Europe from Virginia by the Engliſh; and is by the Americans eſteemed a ſovereign antidote againſt the bite of the rattle-ſnake.

We are told by travellers, that this root not only cures the bite of a rattle-ſnake, but that that animal flies the very ſmell of it; for which reaſon the Indians, and other travellers, always carry it with them on the end of a ſtaff, by way of a preſervative from that creature.

The dried ſerpentaria root is imported into this country in bales, each containing from two to five hundred weight. The dried root has an aromatic odour, not unlike that of valerian; and a ſharp, warm, bitter taſte, reſembling in ſome degree that of camphor. Water extracts all the ſenſible qualities of the root, affording a yellowiſh-brown infuſion, which is not altered by ſulphate of iron or zinc, the nitrate of ſilver, oxymuriate of mercury, tartarized antimony, the mineral acids, and the alkalies; nor is it precipitated by gelatine or tannin. The ſuperacetate of lead throws down a flocculent precipitate, which is not ſoluble in acetic acid, ſhewing the preſence of mucus. With alcohol it affords a bright greeniſh tincture, which is rendered turbid by the addition of water. The active principles of ſerpentaria, therefore, appear to reſide in a bitter reſin; and perhaps camphor, and eſſential oil.

For medical purpoſes, ſerpentaria, or Virginian ſnake-root, is reckoned a ſtimulating diaphoretic and tonic. It is beneficially employed in typhoid and putrid fevers, whether idiopathic, or accompanying the exanthemata, to excite diaphoreſis, and ſupport the powers of the ſyſtem; and is found frequently to increaſe the efficacy of cinchona in removing protracted intermittents. It is alſo an excellent remedy in dyſpepſia, particularly when the ſkin is dry and parched; and is ſometimes uſed as a gargle in putrid ſore-throat. On account of its ſtimulant properties, it is contraindicated when the inflammatory diatheſis is preſent; and previous to its exhibition, the bowels ſhould be well evacuated.

It may be given in ſubſtance, or in infuſion made by macerating ʒiv of the bruiſed root in f℥xij of boiling water, in a covered veſſel for two hours, and ſtraining. Decoction is a bad form of giving ſerpentaria, as the boiling diſſipates the eſſential oil, on which the virtues of the remedy chiefly depend. The doſe of the powdered root is grs. x, or grs. xx, increaſed to ʒſs; that of the infuſion f℥jſs to f℥ij, every fourth hour.

The officinal preparations are as follow: *viz.* the "tinctura ſerpentariæ," the "tinctura cinchonæ compoſita," and the "electuarium opiatum." The "tincture of ſnake-root" of the Lond. and Dub. pharmacopeias is prepared by macerating for fourteen days (ſeven days, Dub.) three ounces of ſnake-root (cut and bruiſed, Dub.) in two pints of proof ſpirit, and filtering. The "tinctura ariſtolochiæ ſerpentariæ," or "tincture of ſnake-root," of the Edinb. Ph., is obtained by digeſting for ſeven days two ounces of ſnake-root bruiſed, a drachm of cochineal in powder, in two pounds and a half of proof ſpirit, and filtering through paper. This tincture is an uſeful addition to infuſion of cinchona in typhoid and putrid fevers, gout, and periodic head-ache. The doſe is from f ʒſs to f ʒij; or when taken in water, as much as can be taken without any injury from the operation of the ſpirit.

The "tinctura cinchonæ compoſita," or "compound tincture of cinchona," of the Lond. and Dub. Ph., is prepared by taking of lance-leaved cinchona bark, powdered, two ounces; dried orange-peel, an ounce and a half (half an ounce, Dub.); Virginian ſnake-root bruiſed, three drachms; ſaffron, one drachm; cochineal in powder, two ſcruples; macerating for fourteen days in twenty fluid-ounces of proof ſpirit, and filtering. This tincture is more grateful than the officinal tincture of cinchona, and though it contains leſs cinchona, yet the addition of the other ingredients renders it more uſeful both as a ſtomachic and a febrifuge. It is the ſame as the celebrated tincture of Huxham, who generally gave it in intermittents and low nervous fevers, in diluted wine or any proper vehicle, with ten or fifteen drops of elixir of vitriol (aromatic ſulphuric acid, Edinb.) The doſe is from f ʒj to f ʒiij, or more, in intermittents. For an account of the "electuarium opiatum," ſee OPIUM. Thomſon's Lond. Diſp.

SNAKE-*Root*, *Rattle.* See POLYGALA *Senega.*

SNAKE-*Root*, *Rattle*, in the *Materia Medica.* See SENEKA.

SNAKE-*Stone*, in *Mineralogy.* See AMMONITE.

SNAKE-*Weed Knot-Graſs*, in *Agriculture*, a common graſs by way-ſides, which, if cultivated, the ſeeds are found to anſwer the ſame purpoſes as thoſe of buck-wheat. It is annual, or at moſt biennial, in its growth.

SNAKE-*Wood*, in the *Materia Medica*, is the wood or root of the tree which affords the nux vomica, or of other trees of the ſame genus. It is brought from the Eaſt Indies under the name of lignum colubrinum, in pieces about the thickneſs of a man's arm, covered with a ruſty-coloured bark, internally of a yellow colour, with whitiſh ſtreaks. This wood, in raſping or ſcraping, emits a faint but not diſagreeable ſmell; and when chewed for ſome time, diſcovers a very bitter taſte.

From the experiments of Cartheuſer, water appears to be the proper menſtruum of its active matter. It has been recommended, in ſmall doſes, not exceeding half a drachm, as an anthelmintic, and in obſtinate quartans, jaundices, cachexies, and other chronical diſorders. It is ſaid to operate moſt commonly by ſweat, ſometimes by ſtool, and ſometimes by vomit. It appears, however, to be poſſeſſed, in a lower degree, of the ſame ill qualities with the nux vomica. Lewis.

SNAKE *Creek*, in *Geography*, a river of Louiſiana, on the north-eaſt ſide of the Miſſouri, in N. lat. 38°, 18 yards wide.

SNAKE *Iſlands*, a cluſter of ſmall iſlands in the Indian ſea, near the coaſt of Africa. S. lat. 5° 20′.

SNAKE *Indians*, a tribe of Indians in Louiſiana, on the ſouth-weſt ſide of the Miſſouri river, near the heads of the Arkanſas, Platte, and Yellow-ſtone rivers. The number of warriors is 200, and of inhabitants 5500. They trade with New Mexico. Theſe Indians, though a very numerous race, are badly armed, and much at the mercy of the other Indians, by whom they are made ſlaves, when taken priſoners. They are alſo called Ayuten bands, and Camanches. They wander about the heads of the Platte, and in the vaſt plains bordering on New Mexico and New Spain, ſouth of the Arkanſas; and are divided into many bands. One of theſe bands is probably that denominated Paunch Indians, who wander along the Rocky mountains, and ſometimes venture acroſs. The Snake Indians poſſeſs a very great number of horſes, aſſes, and mules. Mr. Brackenridge, in his "Views of Louiſiana," obſerves, that theſe Indians were different, both in language and appearance, from any whom he had ever ſeen; and he thinks, that the ſound of the language bears a conſiderable reſemblance to thoſe of Africa which he had heard. We ſhall here ſubjoin a brief account of the river, near which theſe Indians are ſettled. The Arkanſas, next to the Miſſouri, is the moſt conſiderable tributary of the Miſſiſippi. It is nearly 2500 miles in length, and navigable at proper ſeaſons through nearly the whole diſtance. The chief rivers which fall into it are the Verdigris, the Negracka, Canadian river, Grand river, &c. Several are much impregnated with ſalt, and the Arkanſas, at certain ſeaſons, is alſo brackiſh. The lands on this river, for 600 or 800 miles upwards, are deſcribed as very fine, and capable of affording ſettlements, though principally untimbered. There is a remarkable communication between the Arkanſas and White river, by a channel connecting the two rivers, with a current ſetting alternately out of the one or the other, as the flood in either happens to predominate. The Platte is the longeſt and largeſt of the rivers which diſcharge themſelves into the Miſſouri, being little ſhort of 2000 miles, and yet it can hardly be reckoned a navigable ſtream; the channel being very wide, and the quickſands, with which it abounds, ever varying. Several fine navigable rivers, however, diſcharge themſelves into it; ſuch are the Elk Horn, the Wolf river, and the Padoncas Fork.

The Yellow-ſtone, or Roche Jaune, much reſembles the Miſſouri in extent and difficulty of navigation, and is a very conſiderable river. After the junction, the Miſſouri undergoes a very perceptible change. In ſeaſons of high water, it is more properly a ſound, and indeed the deſcriptions of its rapidity are almoſt incredible. It enters the Miſſouri 1880 miles up. Its principal branches are Big Horn, Tongue river, and Clark's river.

SNAKENBURG, a town of Brandenburg, in the Old Mark, on the Elbe; 10 miles N. of Sechauſen.

SNAKING, in the *Practice of Rigging*, a ſort of faſtening to confine the outer turns of ſeizings, &c. with the ſame ſize rope, line, ſpun-yarn, &c. by paſſing it acroſs and under the outer turns at angles; ſo that one part may remain perfect and independent, if the other ſhould be ſhot away.

SNAP-DRAGON, or *Calf's-Snout*, in *Botany*. See ANTIRRHINUM.

The leaſt ſort of this plant is ſometimes a troubleſome weed in corn-fields, but it is annual in its growth, and, of courſe, with care, eaſily and readily deſtroyed by preventing its flowering and producing ſeeds.

SNAP-DRAGON *of America*. See RUELLIA and BARLERIA.

SNAPE, in *Anchor-Making*, denotes the ſudden diminution of any part.

SNAPPERTUNA, in *Geography*, a town of Sweden, in the province of Nyland; 7 miles E.N.E. of Eknas.

SNAP-TREE, in *Botany*. See JUSTICIA.

SNARES, in *Geography*, a cluſter of craggy iſlands in the South Pacific ocean, diſcovered by Capt. Vancouver, on the 24th of November, 1791, and appearing without verdure. The north-eaſternmoſt, which is the largeſt, he apprehended to be equal in extent to all the reſt; it is about 9 miles in circuit, and may be ſeen 8 or 9 leagues off. It is ſituated in S. lat. 48° 3'. E. long. 166° 20'. Mr. Broughton alſo diſcovered theſe iſlands on the 23d of the ſame month, and in paſſing through them, called the largeſt "Knight's Iſland;" which ſee.

SNARNVIER, a town of Aſiatic Turkey, in the province of Sivas, anciently called "Synoria," and once the place where Mithridates kept his treaſures; 25 miles S.S.W. of Arabkir.

SNATCH-BLOCKS, in *Block-Making*. See BLOCKS.

SNATHE, in *Agriculture*, a term applied to the handle of a ſcythe.

SNAYERS, PETER, in *Biography*, a painter of very conſiderable merit in almoſt every branch, but particularly in battles, huntings, and landſcapes. He was born at Antwerp in 1593, and was a diſciple of Henry van Balen. He was held in great eſtimation by the archduke Albert, who patronized him, appointed him his painter, and ſent ſeveral of his pictures into Spain. Beſides this ſuperior encouragement, he was employed for many of the churches in the Netherlands, and his battle-pieces are to be found in all the moſt choice collections of that country. Rubens and Vandyck honoured them with their approbation; and the latter painted the portrait of Snayers among the eminent artiſts of the day. He died in 1670, aged 77.

SNEATH, or SNEYTH, in *Agriculture*, a term applied to the ſhaft of a ſcythe in ſome places.

SNECK, in *Rural Economy*, provincially the latch of a door or gate.

SNECKEN, in *Geography*, a town of Pruſſian Lithuania; 8 miles W.S.W. of Tilſit.

SNEECK, a town of Holland, in the province of Frieſland, ſituated in the country of Weſtergoo, called by the natives "Snitz." The town is well-built, and encompaſſed by ditches and ramparts. Several learned men have been educated in the Latin ſchool of this town; 38 miles W.S.W. of Groningen. N. lat. 53° 4'. E. long. 5° 35'.

SNEEZE-WORT, in *Botany*, a ſpecies of *Achillea*; which ſee.

SNEEZE-WORT, *Auſtrian*, a ſpecies of *Xeranthemum*; which ſee.

SNEEZING, in *Medicine*, *Sternutatio*, a violent convulſive motion of the muſcles of reſpiration, which is preceded by a deep inſpiration filling the lungs, then forces the air violently through the noſe, while the lower jaw is at the ſame moment cloſed, and ſhakes the head and whole body. See LUNGS.

Sneezing is always excited by ſome irritation affecting the inner membrane of the noſe; and the air, therefore, which in coughing is expelled through the mouth, is vehemently driven through the noſtrils in ſneezing, for the purpoſe of expelling that irritation. When a perſon is about to ſneeze, he perceives a ſort of gentle and agreeable tickling in the noſe, and ſometimes there is alſo a ſimilar ſenſation about the præcordia: when one or both theſe are felt, the perſon is obliged to ſuſpend all the bodily actions and wait the event; the whole effort of the body appears to be centered in the convulſion which enſues, and the expulſion of the air through the noſtrils is accompanied by the peculiar noiſe ſo well known. In general, one or two of theſe convulſive efforts effects the purpoſe of removing the irritating cauſe; but caſes are recorded, in which the repetition and violence of the convulſion have been increaſed to the extent of becoming a diſeaſe; and, in perſons of an apoplectic diſpoſition, it is even ſaid to have induced that diſeaſe, and thus to have proved fatal. (See a caſe related by Morgagni, De Sed. et Cauſ. Morborum, Epiſt. xiv. art. 27.) It is clearly demonſtrable, indeed, as Van Swieten has ſhewn, that continued paroxyſms of ſneezing tend to load the veſſels of the head with blood: for the violent contraction of the cheſt impedes for the time the paſſage of the blood through the lungs, and therefore obſtructs the return of the venous blood from the head, the veſſels of which neceſſarily become diſtended. That this is actually the caſe is evident from the appearances; becauſe, on a repetition of ſneezing, the face ſwells and looks redder, the eyes water and appear full and diſtended;

diſtended, and the noſe drops from the increaſed ſecretion into its cavities. (Van Swieten Comment. ad Aph. 271.) Its occaſional dangerous violence is ſaid to have been the cauſe of the benediction, ſo univerſally beſtowed on thoſe who ſneeze, of which we ſhall ſay more preſently.

The cauſes of ſneezing are various, and conſiſt not only of irritating matters immediately ſtimulating the lining membrane of the noſe, but of ſympathetic irritations from neighbouring, or even from diſtant parts. Any extraneous body brought into contact with the pituitary membrane, ſuch as inſtruments, and eſpecially irritating powders, ſuch as ſnuff, or even its own mucous fluids, under particular ſtates, will excite ſneezing. As a direct communication exiſts between the eyes and the noſtrils, into which the tears are conſtantly paſſing through the lacrymal ducts, a reverſe ſympathy is excited in many people by irritations of the eye, ſo that the membrane of the noſe is at the ſame time titillated; whence, in ſuch perſons, ſneezing is immediately excited by ſudden expoſure to a ſtrong light, as by paſſing from a ſhade into a bright ſun-ſhine, eſpecially where that is ſtrongly reflected from ſnow or a white pavement. Other ſympathies have been mentioned by medical authors, eſpecially irritations in the lungs, and alſo in the ſtomach and bowels, as the cauſes of ſneezing. Thus it has been produced by carbonic acid gas, by fermenting beer, by eating ſhell-fiſh, by worms in the alimentary canal, by a leaden ball remaining in the region of the diaphragm, and even by more diſtant irritations, as by the diſtention of the gravid uterus in pregnancy, diſeaſes of the head, &c. See Richter's Bibliotheca, vi. 730. See alſo Sauvages Noſol. Method. who makes ſeven ſpecies of *ſternutatio* from theſe various cauſes.

It is only in theſe rare caſes in which ſneezing, being connected with ſome other diſeaſe, becomes the object of medical treatment; and then of courſe it can only be remedied by curing the diſeaſes, or removing the diſtant irritations, from which it originates. Like other ſpaſmodic affections, however, it may be alleviated by opiates, with camphor and ether, and ſimilar antiſpaſmodics. It would be fruitleſs to mention many of the inert remedies that have been propoſed; ſuch as bags, filled with aromatic ſubſtances, fixed to the vertex, rubbing the gums, &c.

The cuſtom of *bleſſing* perſons when they ſneeze is derived from very ancient times, and its origin has been variouſly accounted for. Several writers affirm that it commenced in the year 750, under pope Gregory the Great, when a peſtilence occurred, in which thoſe who ſneezed died; whence this pontiff appointed a form of prayer and a wiſh to be ſaid to perſons ſneezing, for averting this fatality from them. But the cuſtom is of much more ancient date. It was accounted very ancient in the time of Ariſtotle, who in his problems has endeavoured to account for it. It is alluded to in the Greek Anthology in an epigram, in which the ſalutation of *ſalve Jupiter*, Ζευ σωσων, is given as a familiar phraſe addreſſed to ſneezers. Pliny alſo queſtions "cur ſternutantes ſalutantur?" (Nat. Hiſt. lib. 28. cap. 2. Anthol. Lipſ. 1794. tom. iii. p. 95.): and Cælius Rhodoginus has an example of it among the Greeks in the time of Cyrus the younger. In Alexander Roſs's appendix to Arcana Microcoſmi, p. 222, it is ſaid, "Prometheus was the firſt that wiſhed well to the ſneezer, when the man, which he had made of clay, fell into a fit of ſternutation, upon the approach of that celeſtial fire which he ſtole from the ſun. This gave original to that cuſtom among the Gentiles, in ſaluting the ſneezer. They uſed alſo to worſhip the head in ſternutation, as being a divine part, and ſeat of the ſenſes and cogitation." For many other paſſages relating to this ſubject, ſee Brand's Obſervations on Popular Antiquities, edited by H. Ellis, vol. ii. p. 456, et ſeq. Theſe teſtimonies are ſufficient to ſhew the antiquity of this cuſtom, and the obſcurity of its origin. It may be added, that ſneezing has been from ancient times alſo conſidered as an *omen;* reſpecting which Pliny has ſome obſervations in the chapter juſt quoted. It is noticed as ſuch in the eighteenth Idyllium of Theocritus; and by Ariſtotle, who has a problem, "why ſneezing from noon to midnight was good, but from night to noon unlucky."

SNEGACIUS, Cyriacus, in *Biography*, in 1590 publiſhed at Erford, a tract upon "Harmony, or the Uſe of the Monochord, an Inſtrument for meaſuring and aſcertaining the Proportion of Sounds by a ſingle String;" of which he aſcribes the invention to the Arabians; the only new idea which we could find in the book, which is written in Latin, and of which the original title is, "Nova et exquiſita Monochordi dimenſio."

The ſame author publiſhed likewiſe, in 1590, an elementary tract, entitled "Iſagoges Muſicæ," in two books, the chief merit of which ſeems to conſiſt in the definitions of muſical terms, with ſhort examples in notation.

SNEIRNE, in *Geography*, a town of Perſia, in the province of Irac.

SNELL, Rodolph, in *Biography*, a reſpectable Dutch philoſopher, was born at Oudenwater in the year 1546. After having occupied the ſtation of profeſſor of Hebrew and mathematics at Leyden for ſome time, he died in 1613, at the age of 67 years. He was a writer of ſeveral works on geometry, and various parts of philoſophy.

Snell, Willebrord, the ſon of the preceding profeſſor, and an excellent mathematician, was born at Leyden in the year 1591, where he ſucceeded his father in the profeſſorial chair in 1613, and where he died in 1626, at the premature age of 35 years. He was the author of ſeveral valuable works and diſcoveries. To him we owe the firſt diſcovery of the true law of the refraction of the rays of light; and this diſcovery was made, as Huygens aſſures us, before it was announced by Des Cartes. Snellius undertook alſo to meaſure the earth; and this operation he effected by obſerving the interval between Alcmaer and Bergen-op-Zoom, correſponding to a difference of latitude of 1° 11′ 30″. He alſo determined the diſtance between Alcmaer and Leyden; and from a mean of theſe meaſurements, he made a degree to conſiſt of 55,021 French toiſes or fathoms. Theſe meaſures were afterwards repeated and corrected by Muſchenbroeck, who then found the degree to contain 57,033 toiſes. His works were numerous, and the principal of them are enumerated in Hutton's Dictionary.

SNELLINCKS, John, was born at Mechlin in 1544. He painted in hiſtory and ſtill-life; but he derives his principal renown from his ſkill in repreſenting battles, particularly attacks of cavalry, which were regarded as pre-eminent among works of that kind. He was honoured by the patronage of the archduke and ducheſs, and moſt of the nobility of his day in the Netherlands, and enjoyed all the gratifications which employment and applauſe are calculated to afford. His taſte in grouping is judicious, and he knew how to take advantage of the circumſtances of a battle to diſplay his knowledge of chiaro-ſcuro with great effect. Vandyck appears to have honoured him with his approbation, and has painted his portrait among the diſtinguiſhed artiſts of his day, and alſo etched a plate of it. He died in 1638, aged 94.

SNET, among *Sportſmen*, the fat of all kinds of deer. Dict. Ruſt.

SNEYDERS, or Snyders, Francis, in *Biography*. This ingenious painter was born at Antwerp in 1579, and was a diſciple of Henry van Balen. At the beginning of his practice he confined himſelf to fruits, flowers, and other objects of ſtill-life; but he ſoon advanced to the imitation of animated nature, and in the repreſentation of animals in all the vigour of life and action, in ſcenes of huntings and fightings, if he has had any rival, he has not been ſurpaſſed for freedom, truth, and energy.

Though Rubens was excellent in ſubjects of this nature himſelf, yet he frequently employed Sneyders to introduce animals into his pictures: and ſuch was his excellence in colouring and execution, that in this dread competition he roſe to a level with his great compeer; and produced an union of ſpirit and effect, which has rarely occurred where two artiſts have been engaged upon one canvas. Sometimes Rubens, and Jordaens alſo, returned the compliment, and painted figures in Sneyders' aſſemblages of beaſts, dead game, fiſh, vegetables, &c. Of theſe combined labours, we have many excellent examples in this country; and as Sneyders lived to the age of 78, and was an induſtrious man, they are not thinly ſcattered on the continent. It is impoſſible not to be ſtruck with the aſtoniſhing facility with which his works are completed; or with the delicacies of drawing, the correctneſs and fulneſs of expreſſion, he has given to his animals, their ferocity or their alarm, even their affection for their young or their benefactor. Vandyck painted an excellent portrait of Sneyders, which was in the Orleans collection, and is engraved in the ſet of his heads. He himſelf handled the point, and has left ſeveral etchings of various animals. They are now become ſcarce. He died in 1657.

SNEYDSBOROUGH, in *Geography*, a town of America, in Amſon county, North Carolina, on the Great Pedee; 120 miles above George-Town.—Alſo, a poſt-town in Richmond county, North Carolina, 418 miles from Waſhington.

SNIADYN, a town of Lithuania, in the palatinate of Brzeſc; 88 miles E. of Pinſk.

SNIATYN, a town of Auſtrian Poland, in Galicia, on the Pruth; 96 miles N. of Lemberg. N. lat. 48° 33′. E. long. 25° 52′.

SNID-SKARON, a ſmall iſland in the gulf of Bothnia. N. lat. 65° 25′.

SNIEGULKA, in *Natural Hiſtory*, the name given by the common people of Poland to a bird of paſſage, that only comes to them in the colder months.

The name ſignifies the *ſnow-bird;* and Rzaczinſki, in his Hiſtory of Poland, calls it *nivalis avis*. The people preſage from its coming, the mildneſs or ſeverity of their winter.

SNIGGLING, a method of fiſhing for eels, chiefly uſed in the day-time, when they are found to abſcond themſelves near weirs, mills, or flood-gates; it is performed thus; take a ſtrong line and hook, baited with a lob or garden-worm, and obſerving the holes where the eels lie hid, thruſt your bait into them by the help of a ſtick, and if there be any, you ſhall be ſure to have a bite; and may, if your tackling hold, get the largeſt eels.

SNIPE, *Gallinago Minor*, or *Scolopax Gallinago* of Linnæus, in *Ornithology*, a bird well known among the ſportſmen, and which, though in general a bird of paſſage, yet ſometimes remains with us the whole year, and builds and breeds here. Its young are ſo often found in England, that Mr. Pennant doubts whether it ever entirely leaves this iſland. It lives in marſhy places, and builds among reeds in winter, but in the ſummer is found in our higheſt mountains as well as low moors; it lays four or five eggs at a time, of a dirty olive colour, marked with duſky ſpots.

When ſnipes are much diſturbed, particularly in the breeding ſeaſon, they ſoar to a great height, making a peculiar bleating noiſe, and when they deſcend, dart down with great rapidity. The cock is obſerved (while his mate ſits on her eggs) to poiſe himſelf on his wings, making ſometimes a whiſtling and ſometimes a drumming noiſe. Their food is the ſame with that of the woodcock, and they are found in every quarter of the globe, and in all climates. See SCOLOPAX *Gallinago*.

Theſe birds are eaſily taken, by means of lime-twigs in this manner: take fifty or ſixty birchen twigs, and lime them all very well together; take theſe out into places where there are ſnipes, and having found the places which they moſt frequent, which may be ſeen by their dung, ſet the twigs in theſe places, at about a yard diſtance one from another. Other places are thoſe where the water lies open in hard froſt and ſnowy weather; in theſe places alſo, and wherever they are ſuſpected to come to feed, let more lime twigs be placed in the ſame manner. The twigs are not to be placed perpendicularly in the ground, but ſloping, ſome one way, ſome another; the ſportſman is then to retire to a diſtance, and watch the coming of the birds to theſe places. When they fly to them, they naturally take a ſweep round the earth, and by this means they will almoſt always be caught by one or other of the twigs. When the firſt ſnipe is taken, the ſportſman is not to run to take it up, for it will feed with the twig under its wings, and this will be a means of bringing down more of them to the place. When three or four are taken, they may be taken up, only leaving one faſt to entice others; and thus the ſport may be continued as long as there are any birds of this kind about the place. It may be very proper, when the twigs are planted, to go about, and beat all the open and watery places near, that they may be raiſed from thence, and fly to thoſe places where the twigs are placed to receive them. The ſnipe, and alſo the woodcock, are by a late act comprehended under the claſs of GAME.

SNIPE, *Great*, a ſpecies very rarely found in England. See SCOLOPAX *Major*.

SNIPE, *Mire*. See BITTERN.

SNIPE, *Jack*. See JACK *Snipe*, and SCOLOPAX *Gallinula*.

SNIPE-*Bills*, in *Maritime Affairs*, a kind of hooks for faſtening the axle-tree of chain-pumps to the bitts.

SNISNITZA, in *Geography*, a mountain of Boſnia; 8 miles W. of Boſna.

SNIZORT, a town of the iſland of Skye. N. lat. 57° 27′. W. long. 6° 20′.

SNORING, in *Medicine*, *ſtertor*, *ronchus*, a ſound produced by ſleeping perſons in particular poſitions, apparently occaſioned by the vibrations of the palate in a ſtate of relaxation, when the reſpiration is performed by inſpiring and expiring the air through the mouth and the noſe at the ſame time. The ſounder the ſleep, and the more completely therefore the parts are relaxed, the louder and more conſtant the ſnoring. In the profound coma, which conſtitutes the ſleep of apoplexy, ſnoring is a characteriſtic ſymptom; but the apoplectic ſtertor is alſo commonly accompanied by an additional noiſe, ariſing from the ſaliva and mucus, which are not ſwallowed, being forced through the noſtrils, and ſtill more impeding the reſpiration. A ſimilar ſtertor likewiſe occurs in the profound coma produced by an over-doſe of opium, or of wine and ſpirits, which indeed is not always eaſily diſtinguiſhable from common apoplexy, except by the knowledge of the cauſe.

This ſnoring is very different from the noiſy reſpiration, or rattling in the throat, denominated *cerchnos* or *cerchon*, which is made in the larynx and windpipe, by the paſſing of the air through an accumulating fluid, as in caſes of aſthma, or in the laſt ſtruggles of exhauſted life; of the termination of which, in the latter inſtance, this rattling ſound is marked by the attendants as an unerring ſign.

SNORT, in the *Manege*, called in French *ebrouer*, denotes a certain ſound which a horſe of fire makes by breathing through his noſtrils; as if he had a mind to expel ſomething that was in his noſe, and hindered him to take breath.

This noiſe or ſound is performed by means of a cartilage within the noſtrils, called in French *ſouris*. Horſes of much metal ſnort, when you offer to keep them in. See SOURIS.

SNOTTER, in *Rigging*, a ſhort rope ſpliced together at the ends, and ſerved with ſpun-yarn, or covered with hide: it is ſeized to the ſize of the maſt, leaving a bight, wherein is fitted the lower end of the ſprit, which confines it to the maſt.

SNOV, in *Geography*, a river of Ruſſia, which runs into the Deſna, near Beriezin, in the government of Tchernigov.

SNOW, VALENTINE, in *Biography*, an admirable performer on the trumpet, whoſe exquiſite tone and fine ſhake muſt be well remembered by many perſons now living, who have heard him at Vauxhall, or in Handel's oratorios.

In 1753 he ſucceeded Shore as ſerjeant-trumpet, a place of 500*l.* a-year; after which promotion he ceaſed to perform in public, which was a ſerious loſs to the frequenters of Vauxhall, where his ſilver tones, having room to expand in the open air, never arrived at the ears of the audience in a manner too loud or piercing.

SNOW, *Nix*, a meteor formed in the middle region of the air, of vapour raiſed by the action of the ſun, or ſubterraneous fire; there congealed, its parts conſtipated, its ſpecific gravity increaſed, and thus returned to the earth in form of little white villi, or flakes.

The ſnow we receive, may properly enough be aſcribed to the coldneſs of the atmoſphere through which it falls. When the atmoſphere is warm enough to diſſolve the ſnow before it arrives at us, we call it *rain;* if it preſerves itſelf undiſſolved, it makes what we call *ſnow*. See EVAPORATION.

Dr. Grew, in a diſcourſe of the nature of ſnow, obſerves, that many parts of it are of a regular figure, for the moſt part ſo many little rowels, or ſtars of ſix points; and are perfect and tranſparent ice, as we ſee on a pond, &c. Upon each of theſe points are thoſe collateral points, ſet at the ſame angles as the main points themſelves; among which there are divers other irregular ones, which are chiefly broken points, and fragments of the regular ones: others, alſo, by various winds, ſeem to have been thawed, and frozen again into irregular cluſters; ſo that it ſeems as if the whole body of ſnow were an infinite maſs of icicles irregularly figured. A cloud of vapours being gathered into drops, the ſaid drops forthwith deſcend; upon which deſcent, meeting with a freezing air as they paſs through a colder region, each drop is immediately frozen into an icicle, ſhooting itſelf forth into ſeveral points; but theſe ſtill continuing their deſcent, and meeting with ſome intermitting gales of warmer air, or, in their continual waftage to and fro, touching upon each other, ſome of them are a little thawed, blunted, and again frozen into cluſters, or entangled, ſo as to fall down in what we call flakes.

Clouds of ſnow, ſignior Beccaria obſerves, differ in nothing from clouds of rain, (ſee RAIN,) but in the circumſtance of cold, which freezes them. Both the regular diffuſion of ſnow, and the regularity in the ſtructure of the parts of which it conſiſts, (particularly ſome figures of ſnow or hail, which he calls *roſette*, and which fall about Turin,) ſhew the clouds of ſnow to be actuated by ſome uniform cauſe, like electricity. He even endeavours, very particularly, to ſhew in what manner certain configurations of ſnow are made, by the uniform action of electricity. He adds, that his apparatus never failed to be electrified by ſnow, as well as by rain; and that a more intenſe electricity unites the particles of hail (ſee HAIL) more cloſely than the more moderate electricity does thoſe of ſnow. Lett. dell' Elletriciſmo, p. 520, &c. Prieſtley's Hiſt. &c. of Electricity, vol. i. p. 432.

The lightneſs of ſnow, although it is firm ice, is owing to the exceſs of its ſurface, in compariſon to the matter contained under it; as gold itſelf may be extended in ſurface till it will ride upon the leaſt breath of air.

The uſes of ſnow muſt be very great, if all be true that Bartholine has ſaid in its behalf, in an expreſs treatiſe "De Nivis Uſu Medico." He there ſhews, that it fructifies the earth (which, indeed, is a very old and general opinion); and that it preſerves from the plague, cures fevers, colics, tooth-aches, ſore-eyes, and pleuriſies, (for which laſt uſe, his countrymen of Denmark uſually keep ſnow-water gathered in March). He adds, that it contributes to the prolongation of life; giving inſtances of people in the Alpine mountains that live to great ages: and to the preſerving of dead bodies; inſtances of which he gives in perſons buried under the ſnow in paſſing the Alps, which have been found uncorrupted in the ſummer, when the ſnow is melted.

He obſerves, that, in Norway, ſnow-water is not only their ſole drink in the winter; but ſnow even ſerves for food; people having been known to live ſeveral days without any other ſuſtenance.

Indeed, the generality of the medicinal effects of ſnow are not to be aſcribed to any ſpecific virtue in ſnow, but to other cauſes.

It fructifies the ground, for inſtance, by guarding the corn, or other vegetables, from the intenſer cold of the air, eſpecially from the cold piercing winds; and it preſerves dead bodies, by conſtipating and binding up the parts, and thus preventing all ſuch fermentations, or internal conflicts of their particles, as would produce putrefaction.

It has been a vulgar opinion, very generally received, that ſnow fertilizes the lands upon which it falls more than rain, in conſequence of the nitrous ſalts which it is ſuppoſed to acquire by freezing. But it appears from the experiments of Margraaf, in the year 1751, that the chemical difference between rain and ſnow-water is exceedingly ſmall, and that the latter, however, is ſomewhat leſs nitrous, and contains a ſomewhat leſs proportion of earth than the former; but neither of them contain either earth or any kind of ſalt in any quantity, which can be ſenſibly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of land, which many are, upon good grounds, diſpoſed utterly to deny, yet ſo very ſmall is the quantity of it contained in ſnow, that it cannot be ſuppoſed to promote the vegetation of plants upon which the ſnow has fallen.

The peculiar agency of ſnow as a fertilizer, in preference to rain, may, without recurring to nitrous ſalts, erroneouſly ſuppoſed to be contained in it, be rationally aſcribed to its furniſhing a covering for the roots of vegetables, by which they are guarded from the influence of the atmoſpherical cold, and the internal heat of the earth is prevented from eſcaping. Snow may alſo fertilize the earth, agreeably to the hypotheſis of thoſe who make oil the food of plants, by means of the oily particles which it contains: beſides, ſnow, in melting, moiſtens and pulverizes the ſoil which had been bound up by the froſt, and thus fits it for the abſorption of the vernal dews and rain; and as its water has a tendency to putrefaction, it ſeems, on many accounts, without admitting it to contain any nitre, to be admirably adapted to promote vegetation. Watſon's Chem. Eſſ. vol. ii. p. 77, &c.

It is ſuppoſed by Dr. Darwin, that it may be true, that ſnows of long duration in our winters may be leſs injurious to vegetation than great rains and ſhorter froſt. Firſt, becauſe great rains carry down many thouſand pounds worth of the beſt manure into the ſea; whereas ſnow diſſolves gradually, the upper ſurface, as it thaws, ſliding over the under part, which remains frozen, and thence carries away leſs from the land into the rivers; whence a ſnow flood may be diſtinguiſhed from a rain flood by the tranſparency of the water. Secondly, ſnow protects vegetables from the ſeverity of the froſt; ſince it is generally in a ſtate of thaw where it is in contact with the earth; as the earth's heat is 48°, and that of thawing ſnow 32°. The plants between them are generally kept in a degree of heat about 40°, by which many of them are preſerved. On this account, ſome plants from Siberia were ſaid to periſh by the froſts at Upſal; becauſe the ſnows did not commence at the ſame time as in the colder climate from which they were brought. And thus, ſays he, the lichen rangiferinus, coral moſs, vegetates beneath the ſnow in Siberia, where the degree of heat is always about 40°; that is, in the middle between the freezing point and the common heat of the earth. And as this vegetable is, for many months of the winter, the ſole food of the rein-deer, who digs furrows in the ſnow to find it; and as the milk and fleſh of this animal are almoſt the only ſuſtenance which can be procured by the natives during the long winters of thoſe higher latitudes, this moſs may be ſaid to ſupport ſome millions of mankind. And it is added, that ſnow protects vegetables, that are covered by it, from cold, both becauſe it is a bad conductor of heat itſelf, and contains much air in its pores. When living animals are buried in ſnow, as ſheep, or hares, the water which their warmth produces, becomes abſorbed into the ſurrounding ſnow by capillary attraction, and the creatures are not moiſtened by its dropping on them; but the cavity enlarges, as the ſnow diſſolves, affording them both a dry and a warm habitation. If this was generally known, many cold and weary travellers in ſnowy nights might be ſaved by covering themſelves with ſnow, inſtead of endeavouring to proceed. It ſhould be added, he ſays, that Haſſenfratz has endeavoured to ſhew, by ingenious chemical experiments, that rain-water and ſnow contain both of them a redundancy of oxygen, compared with river-water, which they may have acquired in their deſcent through the atmoſphere; and that as oxygen is ſhewn by the experiments of Ingenhouz and Senebier, to promote the growth of ſeeds and of plants, he concludes that rain-water and ſnow promote vegetation in a much greater degree than river-water and ice, which ſeems to accord with the popular obſervations on this ſubject.

Deep and drifting ſnows are often very dangerous and troubleſome on ſheep-farms, and the elevated tracts on which they are kept during the winter ſeaſon, ſo as to require and demand much attention in the ſhepherd to prevent their fatal effects and conſequences.

It is a popular error, that the firſt ſnow that falls in the year has particular virtues. In Italy they cool their wines all the ſummer with ſnow-water.

Snow may be preſerved by ramming it down in a dry place under ground, and covering it well with chaff. At Leghorn they uſe barley chaff for this purpoſe.

Snow and ice are alſo preſerved with ſtraw or reeds. Mr. Boyle has deſcribed the manner in his experimental hiſtory of cold. See ICE and ICE-*Houſe*.

It is uſual in hot countries to mix ſnow and ice with their wine. Hence Pliny ſays, "Hi nives, illi glaciem potant, pœnaſque montium in voluptatem gulæ vertunt."

Signior Sarotti, in the Philoſophical Tranſactions, mentions a *red*, or *bloody* ſnow, which fell on the mountains La Langhe, near Genoa, on St. Joſeph's day. This ſnow, when ſqueezed, yielded a liquor of the ſame red colour.

Snow of a very bright red colour has ſometimes been found on the ſummits of the higheſt mountains. The matter which colours it burns with a ſmell ſimilar to that of a great many vegetable ſubſtances. Sauſſure, who often collected ſuch ſnow on the Alps, was induced by this property, as well as by its being found in ſummer, and in places where many plants were in flower, to conſider the colouring matter as the farina of ſome plant. C. Ramond, who found this duſt on the ſnow of the Pyrenees, remarked, that it is heavier than water, and hence ſuſpected it to be of mineral origin; and he, indeed, found that it ariſes from the decompoſition of certain micas. This decompoſition requires, without doubt, the conditions mentioned by Sauſſure; for C. Ramond found, that they are neceſſary on the Pyrenees, as well as on the Alps.

SNOW, in *Sea Language*, is generally the largeſt of all two-maſted veſſels employed by Europeans, and the moſt convenient for navigation. The ſails and rigging on the main-maſt and fore-maſt of a ſnow are exactly ſimilar to thoſe on the ſame maſts in a ſhip, only that there is a ſmall maſt behind the main-maſt of the former, which carries a ſail nearly reſembling the mizen of a ſhip. The foot of this maſt is fixed in a block of wood on the quarter-deck, abaft the main-maſt, and the head of it is attached to the after-part of the main-top. The ſail, which is called the try-ſail, is extended from its maſt towards the ſtern of the veſſel. When ſloops of war are rigged as ſnows, they are furniſhed with a horſe (ſee HORSE), which anſwers the purpoſe of the try-ſail-maſt, the fore-part of the ſail being attached by rings to the ſaid horſe, in different parts of its height. Falconer.

SNOW-*Ball Tree*, in *Botany*, a ſpecies of *Viburnum*; which ſee.

SNOW-*Berry*. See CHIOCOCCA.

SNOW-*Berry Buſh*, a ſpecies of *Lonicera*; which ſee.

SNOW-*Bird*, in *Ornithology*, the EMBERIZA *Nivalis* of Linnæus; which ſee.

Theſe birds are called in Scotland *ſnow-flakes*, becauſe they appear in hard weather and in deep ſnows. Some few breed in the Highlands, on the ſummits of the higheſt hills, but the greateſt number migrate from the extreme north. Their appearance is a certain forerunner of hard weather and ſtorms of ſnow, being driven by the cold from their common retreats. Their progreſs ſouthward is probably thus: Spitzbergen and Greenland, Hudſon's Bay, the Lapland Alps, Scandinavia, Iceland, the Ferro iſles, Shetland, Orknies, Scotland, and the Cheviot hills. They viſit, at that ſeaſon, all parts of the northern hemiſphere, Pruſſia, Auſtria, and Siberia. They arrive lean and return fat. In their flight they keep cloſe to each other, and fling themſelves collectively into the form of a ball, at which inſtant the fowler makes great havock among them. Pennant.

SNOW-*Drop*, in *Botany*. See GALANTHUS.

SNOW-*Drop, Great*. See LEUCOIUM.

SNOW-*Drop Tree*. See CHIONANTHUS.

SNOW-*Maill*, in *Sheep Farming*, a term uſually applied by the farmers in the northern parts of the iſland, to the ſum of money paid to any perſon who may be in poſſeſſion of low grounds, for permitting their ſheep to feed thereon in times of deep ſnows.

SNOW-*Plough*, in *Rural Economy*, a contrivance made uſe of in Sweden, and other northern countries, for the purpoſe of clearing roads from ſnow; and which might probably be employed here with advantage in the ſame intention. It conſiſts of a ſhaft, to which the horſes are yoked, uſually two a-breaſt, and one before. The ſides are conſtructed of three or four deals, well jointed and nailed together, having more or leſs height, according as the ſnow is more or leſs deep, as from three to four feet. The length is uſually about fifteen feet, and two iron bars are nailed to the bottom, to make it ſlide with greater facility. It has alſo a box for the purpoſe of being loaded, to keep it down. It may have any breadth, from fifteen to twenty feet, according as the ſnow may want clearing. There is a repreſentation of an implement of this kind in the firſt volume of Communications to the Board of Agriculture.

SNOW-*Stone*, in *Natural Hiſtory*, a name given by ſome to a very beautiful ſtone found in America; of which the Spaniards are very fond, making it into tables, and other ornaments, in their houſes. Alonſo Barba, who had ſeen much of it, tells us, that it is found in the province of Atacama, uſually in pieces of four feet long, and four or five inches broad; ſo that they are forced to join them in the working. Its general thickneſs is about two inches. It has a great variety of colours, which form clouds and variegations of a very beautiful kind. The principal colours are red, yellow, green, black, and white. The white is generally formed into ſpots on the very blackeſt parts of the maſs, and is ſo beautifully diſpoſed, that it repreſents ſnow falling in all its whiteneſs upon a jetty ſurface.

SNOW *Mountains*, in *Geography*, a range of lofty mountains, which forms an extenſive diſtrict in Southern Africa, near the Cape of Good Hope. The whole range of hills which is included under this name forms a large group, of which the two great parallel chains from the weſt, with another not leſs extenſive chain from the north-eaſt, and a ſmaller from the ſouth, are all united. The name, in itſelf, indicates a pretty conſiderable height; and, in fact, the higheſt point, called the "Compaſs-Hill," is, according to the calculations of colonel Gordon, about 300 feet higher than the ſummit of the "Kamberg," and, conſequently, 6500 feet above the level of the ſea. This hill is diſtinguiſhed more particularly from all others in Southern Africa, by being leſs inſulated; or, in other words, it is ſurrounded every way by hills of a conſtantly decreaſing elevation, till they are loſt at length in the plain. On all ſides, the ſlopes are gradual from the ſummit, ſo that the traveller may be conſtantly aſcending for ſeveral days together, by tolerably commodious paths, without encountering any dangerous ſteeps, any deep chaſms, or rugged precipices. The heights are all rounded like domes; the valleys are ſpacious and open; and even conſiderable plains ſtretch in ſome places between one aſcent and the next. The aſpect of the whole mountain is rather naked and uniform than wild and majeſtic: on account of the gentleneſs of the acclivity, and the level nature of the valleys, the water does not ruſh down in torrents, or form deep channels, but rather ſinks into the earth; and to this circumſtance the fertility of theſe mountains is to be principally aſcribed. In its marſhy hollows, the horned cattle find excellent paſture, and the ridges and heights being ſcattered over with ſmall aromatic plants, the ſheep are furniſhed with an abundant ſupply of the moſt ſalutary nouriſhment. The climate in the higher parts is cold in winter, and deep ſnows fall, which continue to lie upon the ground for many weeks. Nevertheleſs, the greater part of the country is habitable; the inhabitants of the other parts that are not ſo, deſcend into ſome of the lower parts, where they have a "legplaats," or winter habitation, during the ſhort period in which they are obliged to quit their more elevated ſituation. In this reſpect the Snow mountains have a very decided preference over the Roggeveld; and, beſides, the weather, in winter, though cold, is clear and bright, whereas, in the Roggeveld, there are often thick fogs, which are very injurious to the cattle.

Three conſiderable rivers have their ſources in the Snow mountains, which are conſtantly ſupplied with water through the whole year, from the melted ſnows and the rain-water. Towards the S. flows the Zondag's river; towards the E. ſeveral ſmall ſtreams, which at laſt unite to form the great Fiſh river; and at the foot of the mountains on the N. ſide, riſes the Sea-Cow river, which flows into the Orange river, which latter, ſubſequent to this union, continues its courſe for more than 100 miles, when it falls into the ſea on the weſtern coaſt. Both the other rivers run in a ſoutherly direction.

The upper ſtratum of the Snow mountains conſiſts of a large-grained ſand-ſtone, intermingled at intervals with quartz. Lower down they conſiſt of a ſchiſt, varying in different parts, both in thickneſs and colour; but no granite is found here. The ſoil throughout is a ſoft argile, which, as well as the ſand-ſtone, is in many parts very much oxydated. The ground is almoſt every where ſtrewed with looſe ſtones, which very much contribute to keep it cool in ſummer, and alſo aſſiſt in promoting the vegetation of the plants. Here is no want of ſprings, and therefore the country is tolerably populous; it is very favourable to the breeding of cattle, and moſt of the inhabitants are in eaſy circumſtances. But through the country the ſprings, though conſtantly flowing, do not yield ſuch an abundance of water as to allow of ſufficiently watering the fields for agricultural purpoſes. On theſe hills no tree grows; and it is juſtly obſerved by Mr. Barrow, that here are people, who in their whole lives never ſaw a wood, or even a copſe. The want of wood prevents a ſupply of fuel, ſo that people are obliged to burn the dung of their cattle dried. The bleak wind of winter is particularly adverſe to the cultivation of nut or fruit-trees, and even the oak will not thrive. The locuſts in this country are very numerous, and very deſtructive. Game is abundant, but the lions and leopards do great miſchief among the flocks and herds. But of all the enemies which this country has to dread, the Boſjeſmans are the moſt formidable, whoſe maraudings occaſion annually a loſs of five out of every hundred of the ſheep and oxen. The breeding of ſheep is the moſt important occupation of the coloniſts in theſe parts. The ſheep of this country and of the Roggeveld are the moſt weighty of any in the colony, and their fleſh is reckoned the beſt flavoured. Some farmers have flocks to the amount of 6000 or 7000, and few have leſs than 3000. The cattle are not leſs profitable. The cows give rich milk in abundance, more ſo than in other parts; and great quantities of butter are carried to Cape Town. Mr. Barrow reckons that a herd of 50 cows will produce at leaſt 100 pounds of butter in a week. The inhabitants of the Snow mountains are a vigorous and cheerful race. Mr. Barrow, it is ſaid, aſſociated with ſome of the moſt worthy and reſpectable people of the colony, and ſeems to have entertained too favourable an opinion of their general character, as others have found them leſs friendly and hoſpitable. It is obſerved, that without ſuch dogs as this country affords, it would be abſolutely uninhabitable. By theſe the inhabitants are defended, not only from their four-footed enemies, but alſo from the Boſjeſmans. Nothing can be compared to their watchfulneſs; the leopard, the jackal, even the lion himſelf, are terrified with the barking of the faithful troop, and haſten to retreat.

SNOW-BIRD Lake, a lake of North America, W. of Hudſon's bay; 12 miles wide from E. to W., but from N. to S. much more extenſive.

SNOWDON Mountains, a cluſter or ridge of lofty hills in the county of Caernarvon, North Wales, are ſituated to the S.E. of the county-town, ſtretching to the confines of Merionethſhire. They are called by the Welſh the mountains of Eryri, and according to an ancient proverb, mentioned by Giraldus, were conſidered to be ſo extenſive and productive, as to be capable of affording ſufficient paſture for all the herds in Wales, if collected together. The ſame author informs us, that there were two lakes on the high part of theſe hills, one of which was remarkable for a floating iſland, and the other for three kinds of fiſh, *viz.* eels, trout, and perch, which had "only one eye, the left being wanting." The higheſt ſummit of this ridge is called by the inhabitants Y Wyddfa, or the Conſpicuous, and by the Engliſh, ſpecially Snowdon. Though confeſſedly the higheſt mountain in Wales, being, according to Pennant, 3567 feet above the level of the ſea, it is by no means the moſt pictureſque in its form; for Cadair Idris, Moelwyn, and Arran, in North Wales, and the Cadair Arthur, near Brecknock, in South Wales, preſent a far bolder outline. Camden remarks of theſe mountains, that they may be very properly termed the Britiſh Alps; "for beſides that they are the higheſt of all the iſland, they are alſo no leſs inacceſſible by reaſon of the ſteepneſs of their rocks than the Alps themſelves; and they all encompaſs one hill, which far exceeding the reſt in height, does ſo towre its head aloft, that it ſeems, I ſhall not ſay to threaten the ſky, but to thruſt its ſummit into it. It harbours ſnow continually, being throughout the year covered with it, or rather with a hardened cruſt of ſnow, and hence the Britiſh name of Craig Eryri, and the Engliſh one of Snowdon."

Snowdon was held as ſacred by the ancient Britons, as Parnaſſus was by the Greeks, and Ida by the Cretans. It is ſtill ſaid, "that whoſoever ſlept upon Snowdon would wake inſpired, as much as if he had taken a nap on the hill of Apollo." The Welſh alſo have always had the ſtrongeſt attachment to the tract of Snowdon. It was, ſay they, the appurtenance of the principality of Wales, which the prince and his predeceſſors held from the days of Brute. One of the titles of the prince was that of lord of Snowdon: and, indeed, ſuch was the importance attached to this ſtrong region, that when Llewellyn was at his laſt extremity, he rejected "the propoſal of Edward, of a thouſand a-year, and ſome honourable county in England, to give it up, well knowing that his principality muſt terminate with the ceſſion." When the Engliſh monarch afterwards effected the complete conqueſt of Wales, he held a triumphal fair upon this mountain, and adjourned to finiſh the joy of his victory, by ſolemn tournaments on the plains of Nevin. After this event the tract of Snowdon was annexed to the crown of England, and continued to be a royal foreſt as late as the reign of queen Elizabeth. Leland informs us, that in his days ſtags were found here in ſuch numbers, as to deſtroy the little corn the farmers attempted to ſow; but theſe, Pennant tells us, were extirpated before the year 1626. The ſame author adds, "Snowdon being a royal foreſt, warrants were iſſued for the killing of the deer. I have ſeen one from the duke of Suffolk, dated April 30, 1552, and another in the firſt year of queen Elizabeth, ſigned by Robert Tounesfend; and a third, in 1561, by Henry Sydney. The ſecond was addreſſed to the maſter of the game, ranger, and keeper of the queen's highneſs foreſt of Snowdon, in the county of Carnarvon. The laſt extended the foreſt into the counties of Meirionydd and Angleſea, with the view of gratifying the rapacity of the favourite, Dudley, earl of Leiceſter, who had by letters patent been appointed chief ranger." Pennant's Tour in Wales, vol. ii. 4to. The Itinerary of Archbiſhop Baldwin through Wales, A.D. 1188, by Giraldus de Barri, tranſlated by ſir R. C. Hoare, bart. 4to. 1806. Aikin's Tour in Wales, 8vo. Wyndham's Tour in North Wales, 4to. Hutton's Remarks on North Wales, being the Reſult of Sixteen Tours, 8vo. 1803. Bingley's Tour round North Wales, 2 vols. 8vo. 1800. Caernarvonſhire, or ſome Account of its Antiquities, Mountains, and Productions, 8vo. 1792.

SNOW-HILL, a ſea-port of Maryland, and capital of Worceſter county, ſituated on the S.E. ſide of Pokomoke river, containing about 60 houſes, a court-houſe and gaol; the inhabitants of which deal principally in lumber and corn; 158 miles from Waſhington. N. lat. 38° 11′. W. long. 75° 30′.

SNOWSWICK *Pine-Apple Cheeſe*, in *Rural Economy*, a particular ſort of cheeſe made about that place in Berkſhire, which are of the pine-apple ſhape and external appearance. They are principally made upon the farm of a Mr. Pike, and ſome others, in the pariſh of Buſcot, which are famous for them. They ſell conſiderably higher than thoſe cheeſes which are made in the common forms, and they are juſtly entitled to the diſtinction and increaſe of price, in conſequence of their peculiar richneſs, and the delicacy of their flavour. When kept to the proper age, they are, perhaps, not inferior to any cheeſe in the kingdom.

In regard to the method of making them, the firſt part of the proceſs is exactly the ſame as for the common ſort. The curds are then well worked and broken down with the hands, after which the whole is preſſed into a wooden mould, contrived in the ſhape of a flower-pot, being afterwards hung up and ſuſpended from beams, rafters, or pegs, in an airy apartment, in a net, the meſhes of which mark and indent the ſurface in the manner of the pine-apple. Salt is then rubbed into and over them, or they are ſteeped in a ſuitable brine made from that ſubſtance. On the above perſon's farm, the firſt of theſe methods is thought to be the moſt proper and adviſeable. No ſort of continued preſſure is employed, and yet in firmneſs, it is ſaid, when dry, theſe cheeſes cannot be diſtinguiſhed from thoſe which have undergone the force of preſſure in cheeſe-preſſes.

One of theſe pine-apple cheeſes, for the moſt part, weighs about five pounds, and in good years, it is ſaid, that two tons of them are made on the farm already noticed alone. It is, indeed, ſcarcely known that they are manufactured any where elſe.

Some cheeſes are made in other parts of this diſtrict, as about Stanford, in the Vale, in the fanciful ſhape of a hare ſitting in her form. Theſe are likewiſe ſometimes coloured with ſage. See Cheese and Dairying.

SNUFF, a preparation of tobacco, made by reducing it into a powder, fit to be taken in at the noſe, in order to purge or clear the head of pituita.

Ordinarily, tobacco is the baſis of ſnuff; other matters being only added to give it a more agreeable ſcent, &c. The kinds of ſnuff, and their ſeveral names, are infinite; and new ones are daily invented; ſo that it would be difficult, not to ſay impoſſible, to give a detail of them. We ſhall only ſay, that there are three principal ſorts: the firſt granulated; the ſecond an impalpable powder; and the third the bran, or coarſe part remaining after ſifting the ſecond ſort.

The many miſchiefs attending the unnatural practice of taking this powder of tobacco at the noſtrils, have been deſcribed by the writers in general on theſe ſubjects, ſince this pernicious cuſtom has reigned in the world; but one of the moſt remarkable accidents, occaſioned by it, is related in the Acta Eruditorum, which was the forming of a polypus in the œſophagus, that killed the patient, by ſtarving him, from an inability of ſwallowing. Act. Erudit. an. 1715, p. 475. See Pica *Naſi*.

Snuff, or *Snuffler*, in the *Manege*. See Snort.

SNUG Bay, in *Geography*, a bay in the Straits of Magellan, N.N.W. of Cape Froward.

Snug *Bay Point*, a cape in the Straits of Magellan; 8 miles N.N.W. of Cape Froward.

Snug *Corner Cove*, a bay of the North Pacific ocean, on the E. ſide of Prince William's ſound, on the W. coaſt of North America. N. lat. 60° 50′. W. long. 146° 30′.

SNYING, in *Ship-Building*, a term applied to thoſe planks, whoſe edges curve or round upwards. The great ſny occaſioned in full bows or buttocks is only to be prevented by introducing ſteelers. See Steelers.

SNYTE, in *Geography*, a river of England, which runs into the Dean, in Nottinghamſhire.

SOA, a town of the iſland of Cuba; 60 miles N. of St. Yago.

Soa, a ſmall iſland of the Hebrides, or Weſtern iſlands of Scotland, ſituated near the celebrated iſle of St. Kilda. It is about a mile in circumference.

SOACA, in *Ancient Geography*, a town ſituated in the interior of Arabia Felix, according to Ptolemy.

SOAGGIO, in *Ichthyology*, the name of a fiſh common in the markets of Rome and of Venice, and of the turbot kind. See Lug-*a-leaf*.

SOAID, in *Geography*. See Saidou.

SOAK, or Souiak, a town of Arabia, in the province of Maſcat, on the E. coaſt; 5 miles N.W. of Burka.

SOAKAGE, in *Agriculture*, a term applied to the water that drains through the banks or other parts, in fen and other moiſt diſtricts. It is very conſiderable and troubleſome in ſome inſtances, ſo as to cauſe much expence. See Embankment.

SOAL, or Sole, in *Ichthyology*, the Engliſh name of the fiſh, called by the generality of authors the *bugloſſus*, by ſome *ſolea*, and the Pleuronectes *Solea* of Linnæus, which ſee. Some authors call it the *linguacula*.

The ſoal is found on all our coaſts, but thoſe on the weſtern ſhores are much larger than thoſe of the north. They are uſually taken in a trawl-net; they keep much at the bottom, and feed on ſmall ſhell-fiſh. The ſmall ſoals are much ſuperior in goodneſs to the large ones.

Soals may be taken at any time of the year, but they muſt not be under ſeven inches from the eye to the end of the tail. 1 & 2 Geo. I. cap. 18.

Soal, *Smooth*, from its tranſparency called the *lantern-fiſh*. See Pleuronectes *Arnogloſſus*.

SOALTERPOUR, in *Geography*, a town of Bengal; 20 miles E. of Rangamatty.

SOAMUS, (*Tſhamou*), in *Ancient Geography*, a river of India, on this ſide of the Ganges. Its ſource was in mount Emodus, S. of the Hydaſpes, into which it diſcharged itſelf N.E. of Bucephala.

SOANA, a river of Aſiatic Sarmatia, the mouth of which is placed by Ptolemy on the weſtern coaſt of the Caſpian ſea, above the town of Telcha.—Alſo, a river of the iſland of Taprobana, ſo called by Ptolemy, who places its mouth on the weſtern coaſt, between the promontory of Andraſimundum and the town Sindocanda. —Alſo, a town of Italy, in Etruria, N.W. of the Volſinii.

Soana, in *Geography*, a town of Etruria, the ſee of a biſhop, ſuffragan of Sienna; 24 miles N.E. of Orbitello.

Soana, a mountain of France; 10 miles S. of Aoſta.

SOANDA, or Soandus, in *Ancient Geography*, a town of Cappadocia, between Therma and Sacæna, according to the Itinerary of Antonine.

SOANE, in *Geography*, a river of Hindooſtan, which riſes in the country of Allahabad, about 30 miles S.E. from Sohagepour, and runs into the Ganges, near Patna.

SOANEN, John, in *Biography*, a French prelate, was born at Rioms in 1647. His father was an attorney in the preſidial court of that city; his mother was niece of the learned Jeſuit Sirmond. In 1661 he entered the congregation of the Oratory at Paris, where he took for his confeſſor the celebrated father Queſnel. After teaching the languages and rhetoric in ſeveral of the ſeminaries of the ſociety, he devoted himſelf to pulpit ſervices, and with ſo much ſucceſs, that he became one of the four diſtinguiſhed preachers of the congregation, who were popularly denominated the four evangeliſts. Fenelon joined him with Maſſillon as models of pulpit eloquence. In 1695 he was placed in the ſee of Seneza, a biſhopric of ſmall revenue, but which, being in a retired ſituation, required little of the parade of office, and permitted him to expend the greateſt ſhare of his income in charity. To his various virtues as a Chriſtian paſtor, he united a firmneſs which enabled him to ſuſtain the part of a martyr to principle. On the publication of the bull Unigenitus, which contained a condemnation of Queſnel's opinions, he appealed againſt it to a future council, and publiſhed a paſtoral letter, in which he controverted its poſitions with great force of argument. Cardinal Fleury, reſolving to make an example of a diſobedient prelate, ſelected Soanen for a victim; and in 1727, aſſembling the council of Embrun, procured a condemnation of the licentious biſhop, who was ſuſpended from his prieſtly and epiſcopal functions, and exiled. In his retreat he had numerous viſitors, who paid him the reſpect due to his virtue and integrity. He died in the year 1740, at the age of 92, revered by the Janſeniſts as a ſaint, and condemned by the Moliniſts as a rebel. He was author of "Paſtoral Inſtructions," "Charges," and "Letters," which were printed, with his "Life," in 2 vols. 4to. and 8 vols. 12mo.

SOANES, in *Ancient Geography*, a people of Aſia, in the Colchide, being of the number of thoſe who were in the general aſſembly of Dioſcurias, and who inhabited the ſummits of mount Caucaſus, above the town of Dioſcurias, according to Strabo.

SOANGUR, in *Geography*, a town of Hindooſtan, in Guzerat; 50 miles S. of Surat. N. lat. 21° 10′. E. long. 73° 33′.

SOANK, a town of Hindooſtan, in Bahar; 45 miles S.S.E. of Bahar.—Alſo, a river of Hindooſtan, which riſes near Burwah, in Bahar, and runs into the Bramnee, near Khoud, in Oriſſa.

SOAP, in *Chemiſtry*, is a name for thoſe bodies which are compounds of the alkalies with fat and the fixed oils. The earths and the other metallic oxyds alſo combine with fat and oils, forming neutral compounds. The former have been called earthy, and the latter metallic ſoaps.

The ſoaps formed by the alkalies have the diſtinguiſhing character of being ſoluble in water and alcohol. The earthy ſoaps are perfectly inſoluble. And ſince any of the earths have a ſtronger attraction for oil than the alkalies, the alkaline ſoaps are always decompoſed by the earths. This occaſions the curdy appearance when ſoap is uſed with water containing any earthy or metallic ſalt. It is from this quality that waters are ſaid to be hard.

The earthy ſoaps are of a greyiſh-white colour, of a curdy appearance. The metallic ſoaps are of different colours. Both theſe and the earthy ſoaps are formed by adding a ſolution of an alkaline ſoap to a ſolution of an earthy or metallic ſalt. A precipitate is formed, which is the ſoap to be obtained. With a ſolution of iron containing the red oxyd, the ſoap is of an orange-red colour. It has the conſiſtency of a ſalve or plaſter, but by expoſure to the air it becomes dry and friable, but may be ſoftened by heat. When a ſimilar ſolution of ſoap is added to a ſolution of ſulphate of copper, a green ſoap is formed, which is a fluxible maſs like wax. Corroſive ſublimate, treated in this manner, gives a red ſoap. All the metallic oxyds may be combined with fat or oil in a ſimilar way.

Soap, in the *Manufactures* and *Domeſtic Economy*. This is confined to ſoaps made with the fixed alkalies, combined with different kinds of fat and oil. Theſe, in the manufacture of ſoap, are divided into two principal varieties, *viz.* hard and ſoft.

1. *Hard Soap.*—The alkali employed for hard ſoap is ſoda, generally obtained from the different ſea vegetables, and called by different names, according to the name of the plant in different countries. Moſt of the *algæ*, but particularly the *fucus* and *ſalſola*, afford ſoda by burning. The vegetables are firſt dried, and then burnt in pits formed with looſe ſtones. The earthy matter and the ſoda, with ſome neutral ſalts, fuſe into a crude maſs, in which ſtate it is ſold. This ſubſtance is furniſhed in great abundance from the Highlands of Scotland, under the name of *kelp*, and from Alicant in Spain, under the name of *barilla*. In France it is known by the name of *varec*; this being the name of the plant from which it is generally produced there.

It is commonly, however, in this ſtate that it comes to the ſoap-maker, varying frequently in its value, and often occaſioning much uncertainty in its employment. It ſhould be the firſt buſineſs, therefore, of the manufacturer, to aſſay the ſubſtance from which he gets his alkali, even before he purchaſes it. For this purpoſe a given quantity ſhould be dried and weighed. After reducing it to powder, it muſt be treated with hot rain-water, till the water coming from it has no taſte, reſerving all the portions of water added from time to time. Concentrate this liquid by evaporation, till the quantity of liquid is not more than three times the weight of the quantity taken to be aſſayed. Now weigh out a quantity of ſulphuric acid, ſay half the weight of the aſſay. From this quantity take ſmall portions at a time, and add them to the ſolution above-mentioned, ſtirring it at the ſame time with a wooden rod. When the eſcape of gas begins to diminiſh on the addition of freſh acid, let the additional portions be very ſmall. Now take bits of paper ſtained blue with litmus: on dipping one into the liquid, if more acid is wanting, the paper will not be changed, but the moment the paper is turned red by the liquid, ceaſe to add ſulphuric acid. Let the remaining acid be now weighed, in order to know what has been uſed, and note this down. Now take pure ſal ſoda (carbonate of ſoda) in well-formed cryſtals, exactly of the ſame weight with the firſt aſſay, and diſſolve it in three times its weight of pure water. Weigh out the ſame quantity of ſulphuric acid as before, and juſt follow the ſame ſteps as above directed, till the litmus paper juſt turns red, then weigh the remaining acid, to obtain the quantity uſed, and note down as before. Then ſay, as the acid conſumed by the ſal ſoda is to that conſumed by the aſſay, ſo is 100 to a number which will give the *per centage* of carbonate of ſoda contained in the crude alkali. Thirty *per cent.* of the carbonate of ſoda ſo indicated will be real ſoda, the only ſubſtance which combines with the fat to form ſoap. When the exact value of the alkali is known, it is then to be treated as follows, to prepare it for mixing with the fat.

The kelp or barilla is firſt to be pounded, and then mixed with one-fifth its weight of quicklime, in a large vat. Theſe vats are generally three or four in number to each boiler. They are frequently made with brick-work, from four to five-feet cubes, but ſometimes of caſt-iron. Beſides theſe vats for the infuſion of crude alkali, each of theſe has a ſimilar cavity under it. The bottom of the vat is even with the ground, the under vat being ſunk below, and is intended to receive the liquor which runs from a plug-hole in the upper vat, when the infuſion has gone on to a certain extent. One of theſe vats, with its under reſervoir, is ſufficient for one boiling, but they are generally all at work, in order to give time for the ſolution of the alkali from the crude maſs.

In charging a vat, the barilla, kelp, or potaſh, and ſometimes mixtures of theſe, are firſt coarſely powdered, and mixed with quicklime alſo coarſely powdered; ſome water is then thrown upon theſe to ſlake the lime. In the ſide of the vat ſome ſtraw is firſt placed about the plug-hole, to prevent bits from paſſing through. The vat is now charged, and water poured upon the materials till it ſtands conſiderably above the ſolid maſs. After ſtanding ſeveral hours the plug is withdrawn, to let out the ſolution into the lower reſervoir. The plug is now returned, and freſh water poured upon the materials. Some or all the firſt ley is now removed into one of the other lower reſervoirs before the ſecond infuſion is drawn off. This is done, that the ſoap-boiler may always have at command two leys of different degrees of ſtrength, as in the courſe of every boiling he finds it neceſſary to uſe ſometimes the weak and at other times the ſtrong.

The number of waters to be added to the materials depends upon the judgment of the workman, who by his taſte can tell when the water has diſſolved the whole of the alkali. The times of charging the vats are irregular with reſpect to the times of charging the boiler. Some one of the vats is conſtantly employed, in order to inſure a conſtant ſupply of the ley.

The boilers are made to hold from about 20 to 25 cwt. of ſoap; they are made in two parts, the lower part being about three feet in diameter, and the ſame in length: under the bottom of this the fire acts. The top part has a flange, to which the upper part is ſcrewed. The latter is nearly an hemiſphere, riſing above the floor juſt ſufficient to allow the workman to ſtir the ſoap when he ſtands up.

The ley being ready to lade out of the reſervoir, which is near to the boiler, the tallow or oil firſt weighed is put in. When it is ſufficiently melted, the workman begins by adding the ley, and ſtirring the mixture. The alkali and the oil ſoon begin to unite, forming a milky fluid. As more ley is added, and the ſtirring continued, the liquid thickens. This is continued generally for 30 hours, and frequently more, till ſmall portions of the ſoap, taken out from time to time, aſſume a proper conſiſtence, which the workman by conſtant experience underſtands. He now adds a quantity of common ſalt, which has the effect of ſeparating the watery part from the ſoap, which contains a portion of neutral ſalts, that exiſted in the crude alkali, and ſometimes alſo free alkali, eſpecially when more than enough has been added. The fire is now to be withdrawn, and the maſs left to cool. The watery part will be found at the bottom, and requires to be pumped out by a pump, which is a fixture on the ſide of the boiler. When this has been removed the fire is rekindled, and if the maſs does not melt freely, a little water is added. As ſoon as the whole becomes liquid, and is made uniform by agitation with wooden poles, the fire is again withdrawn, and the maſs allowed to aſſume a proper conſiſtence for lading. It is laded into ſquare moulds: theſe are compoſed of a number of ſtrata lying one upon another, ſo that when the ſoap has become ſolid, each layer of frame-work can be removed, beginning at the top, and the ſoap is cut into cakes with a piece of ſmall braſs wire at every interval: theſe cakes are afterwards cut into ſquare priſmatic pieces, in which ſtate they are ſold.

Some manufacturers proceed in a different manner in boiling the ſoap. In the method above deſcribed, and which is practiſed by a judicious ſoap-boiler in Derby, the watery part, or what is called the ſpent ley, is not ſeparated till all the ley is added. This method is called cloſe working, becauſe the liquid is of an uniform thickneſs all the time, till the ſalt is added: it then aſſumes what is called the granular form, in which the watery part is ſeparated from the ſoap, like the whey and the curd in making cheeſe. This ariſes from the ſoap being inſoluble in ſalt-water. In this ſtate the ſoap is ſaid to be open, to diſtinguiſh it from the ſtate in which it exiſts before the ſalt is added, and in which the ſoap is ſaid to be cloſed. In the open working the common ſalt is added at ſeveral intervals, in order to keep the ſoap ſeparated from the water. The fire is alſo withdrawn ſeveral times, and as many times the ſpent leys are pumped off. After each time, except the laſt, freſh ley is added and the ſtirring repeated. The proper ſtate for the ſoap is known by the appearance of the bubbles. The very hard ſoap, or that which is made with all ſoda, is not the moſt convenient for practice; it is neither ſo fit for waſhing the hands, nor ſo eaſily reducible to a pulpy ſtate for the different manufactures in which it is employed. The hard white ſoap, produced in the manufactory above alluded to, is in great repute from its whiteneſs and its proper conſiſtency. This ſoap is formed with tallow and a mixture of ſoda and potaſh. The boiler holds from about 25 to 27 cwt. of ſoap. The following are the average proportions of the materials employed; 13 cwt. 2 qr. 16 lbs. of tallow, 5 cwt. 3 qr. 12 lbs. barilla, 3 cwt. 2 qr. 6 lbs. American potaſh, 4 cwt. 2 qr. 7 lbs. quicklime, and 3 qr. 16 lbs. common ſalt (muriate of ſoda.) Theſe materials produce 1 ton 4 cwt. 0 qr. 1 lb. of white ſoap. The lime, the barilla, and the potaſh, are mixed together, and placed in the vat already deſcribed. In order to furniſh the ley which is added to the melted tallow, the lime is employed merely to rob the potaſh and ſoda of their carbonic acid, and of courſe does not enter into the compoſition of the ſoap. The neutral ſalts, which both the barilla and potaſh contain, are pumped out with the ſpent leys with a portion of uncombined alkali: of this we ſhall ſay ſomething hereafter.

Hence it will appear, that the ſoap is a compound of pure alkali, with the fat, and a portion of water.

In the making of ſoap, as in all other chemical combinations, the proportions appear to be definite. Every ſoap-boiler knows, that where too much ley is added to the fat, the exceſs will be found in the watery part under the ſoap; and that if the fat were in exceſs, the ſoap would be greaſy to the feel, and would otherwiſe ſhew the preſence of uncombined fat. Hence it will be found on analyſis, that the proportions will be uniform, becauſe they are definite. The quantity of ſoda which combines with olive-oil and tallow, is about 30 of the former to 212 of the latter; and ſince an atom of potaſh is to that of ſoda as 29.25 to 44.5, 45 of potaſh will combine with 212 of oil or tallow.

The following is an analyſis of ſoap by Darcet, Lelievre, and Pelletier:

Oil - - -	60.94
Soda - - -	8.56
Water - - -	30.5
	100

If the alkali were potaſh inſtead of ſoda, then the proportions would be,

Oil - - -	58.4
Potaſh - - -	12.3
Water - - -	29.3
	100

In the firſt of theſe analyſes, the ſoda is to the oil as 85 to 609, or as 1 to 7.28 nearly. In the ſecond, the potaſh is to the oil as 12.3 to 58.4, or as 1 to 4.6 nearly. The ſpecimen of ſoap before alluded to contains a mixture of potaſh and ſoda. The 3 cwt. 2 qr. 6 lbs. of American potaſh, according to the average value of that article, ought to give 2 cwt. 2 qr. of pure potaſh. By the above analyſis, the 1 ton 4 cwt. 0 qr. 1 lb. of ſoap ought to contain 7 cwt. 1 qr. 7 lbs. of water. There ought to be therefore only 16 cwt. 3 qr. 21 lbs. of the alkali and tallow. It appears, that in forming this ſpecimen of ſoap, 100 lbs. of common ſalt were added, which gives to the ſoap 55.5 lbs. of ſoda, and takes away from it 83.25 lbs. of potaſh. Hence, the alkali reſulting from the potaſh in this ſoap will be 1 cwt. 3 qr., and 55.5 lbs. of ſoda derived from the common ſalt, or 2 qr. 4 lbs. nearly. In order to know what ſoda is derived from the barilla, we muſt ſubtract the tallow and the alkali from the whole; that is (16 cwt. 2 qr. 27 lbs.) 1 cwt. 3 qr. of potaſh, 2 qr. of ſoda, and 13 cwt. 2 qr. 16 lbs. of tallow, will leave 3 qr. 6 lbs. of ſoda derived from the barilla.

The proportions of the ſoap in queſtion will, therefore, be, in 2689 lbs. of ſoap,

Tallow - - - -	1528	or	57
Soda - - - - -	146		5.4
Potaſh - - - - -	196		7.3
Water - - - - -	819		30.3
	2689		100

This reſult, although it contains a little too much of the mixed alkali to correſpond with theory, is ſtrikingly near the truth. We may therefore conclude, that ſoap, in general, contains from 8 to 12 *per cent.* of alkali, as more or leſs of each prevails, and about 30 *per cent.* of water. The hardeſt white ſoap made with ſoda would contain 8 *per cent.*; and the ſoft ſoap, in which potaſh alone is uſed, would be a little more than 12 *per cent.*

In the above ſpecimen of hard ſoap, it will be ſeen that 398 lbs. of crude potaſh furniſh 280 lbs. of real alkali, which is ſeven-tenths of the whole. With this were employed 656 lbs. of barilla, which furniſh 90 lbs. of real alkali. Now 192 lbs. of American potaſh will produce 135 lbs. of pure potaſh, and this will diſengage from 126 lbs. of muriate of ſoda, or common ſalt, 90 lbs. of pure ſoda. Hence 192 lbs. of American potaſh and 126 lbs. of ſalt will produce as much ſoda as 656 lbs. of barilla.

This weight of barilla, at the preſent price, coſts 10*l.* 5*s.*: 192 lbs. of potaſh will now coſt 6*l.* 17*s.*; and 126 lbs. of common ſalt, 1*l.* 17*s.* Theſe two ſums are 8*l.* 14*s.* The ſaving, therefore, in employing potaſh and common ſalt, in making even the beſt hard white ſoap, inſtead of barilla, is nearly 5 *per cent.* But if the two alkalies are to be contained in equal proportions, then about half the common ſalt only need be uſed, and the ſaving will be very conſiderable. It will alſo appear evident, that ſoap may be made of any degree of hardneſs, by uſing more or leſs of common ſalt with the potaſh; and that if no ſalt at all be uſed, the ſoap will be ſoft.

The difference of price between barilla and potaſh is often much more than at preſent in favour of uſing potaſh: this will make the ſaving above mentioned more conſpicuous.

It muſt alſo be remembered, that ſome ſalt is always uſed for the purpoſe of ſeparating the ſpent leys from the ſoap. This has been ſtated at about three-quarters of a cwt. to 24 cwt. of ſoap. It ſeems that a ſolution of ſalt of this ſtrength does not diſſolve ſoap.

Hard Soap, Yellow.—This ſoap is formed of ſimilar proportions of ſoda and tallow with the laſt; but it alſo contains roſin, and ſometimes palm oil.

The following are the average proportions of the materials for making yellow ſoap, which may be relied upon.

Tallow.	Roſin.	Palm Oil.	Barilla.	Potaſh.	Lime.	Soap produced.
Cwt. qr. lb.						
13 0 11	3 2 18	1 0 0	6 2 14	1 0 16	5 0 9	26 1 21

The whole weight of the materials, excluſive of the lime, and the refuſe of the potaſh and barilla, is equal to 24 cwt. 0 qr. 1 lb.; the ſoap, independent of the water it contains, is 18 cwt. 0 qr. 25 lbs.: this, taken from 24 cwt. 0 qr. 1 lb. leaves 5 cwt. 3 qr. 4 lbs. for the refuſe of the tallow, roſin, and palm oil. That the tallow muſt make much waſte will be eaſily conceived, from the moſt inferior kind being uſed. The roſin and oil muſt alſo yield much refuſe. This refuſe is found all together at the bottom of the pan after boiling, and is known in the manufactories under the name of *nigre.*

In boiling the yellow ſoap, the roſin, oil, and tallow are put into the boiler firſt. The ley is prepared in a ſimilar vat, and managed in other reſpects in the ſame mode as in forming the white ſoap.

The manner too of adding the ley from time to time, and the ſtirring, are juſt kept up in a ſimilar way, till the fatty matter is fully ſaturated. The time required for boiling the quantity of ſoap ſtated above, is ſometimes as much as three weeks, during which time it is kept in what is called the open ſtate, that is, the watery part is completely ſeparated from the ſoap. It would appear that this ſoap requires merely the preſence of the neutral ſalts in ley to keep it in the open ſtate. This ariſes probably from this being a leſs perfect ſoap, and leſs ſoluble in water. The ſoap appears in ſmall lumps, perfectly detached from the fluid. At the end of every day the ſoap is allowed to cool, when the thin part ſinks to the bottom: this is ſpent ley, and is pumped off every morning. The fire is again raiſed, and freſh leys added: the boiling and ſtirring go on again. This action is repeated till the fat is ſaid to be killed. This, as we have obſerved, takes ſometimes fifteen or twenty days. When this change is complete the fire is withdrawn, and the maſs allowed to cool: the laſt ley is pumped out. The addition of a little water, and the fire being raiſed, allow the ſoap to be diſſolved, and the refuſe, which is principally the ſubſtance we have called nigre, is left at the bottom, perfectly diſtinct from the ſoap. When the ſoap is of a proper conſiſtence for caking, it is transferred to the moulds, where it is treated in a manner ſimilar to that already deſcribed in the white ſoap.

It is a queſtion, whether making this inferior ſoap is ſo profitable to the manufacturer as is ſuppoſed. It has appeared, that in making the quantity of ſoap above ſtated, which is 26 cwt. 0 qr. 21 lbs., there are 5 cwt. 3 qr. 4 lbs. of refuſe, which is principally in the nigre. This refuſe will be found very trifling in the white ſoap; we think not more than $\frac{1}{25}$th of the weight of the ſoap. It will be evident, that in making the yellow ſoap, a great quantity of matter is uſed which never combines. Would it not be more economical to purify theſe materials before hand?

Soft Soap.—This differs in its compoſition from hard, in containing no alkali, but potaſh. We have ſeen that hard ſoap may be made not only with pure ſoda, as is the caſe in the manufactories in the ſouth of France, but that a tolerably hard ſoap, much better fitted for practice, is made with about equal portions of potaſh and ſoda.

Soft ſoap made with colourleſs fat, ſuch as tallow, is a white unctuous ſubſtance, about the conſiſtency of lard. If the fat be coloured, the ſoap partakes of the ſame. In France and other parts of the continent, it is generally coloured, ſometimes with metallic oxyds. Thoſe made with yellow oil are ſometimes coloured with indigo, which gives them a green colour. The oils employed are ſeldom olive-oil, but the cheaper oils, ſuch as rape-oil, the oil of hemp-ſeed, lint-ſeed, and others.

In Holland it was made with whale-oil. This oil was forbidden on ſome parts of the continent, on account of its diſagreeable ſmell. In this country, however, all the ſoft ſoaps are made with whale-oil, which gives a tranſparent maſs of a yellow colour. In commerce, however, we do not find it uniform in its colour. Beſides the yellow part, it appears interſperſed with white ſpots, giving the whole a ſtrong reſemblance to the inſide of a dried fig.

The proportions of potaſh and oil, for forming ſoft ſoap, will be eaſily inferred from what has been obſerved in the proportions of the other ſoaps. The white ſpecks are produced by adding a portion of tallow to the oil, when the boiler is charged. This addition does not improve the ſoap, but habit in commerce has rendered it indiſpenſable. The ley is prepared by adding to the potaſh about three-fourths its weight of quicklime, and the proceſs is continued as directed in making the hard ſoap, uſing the ſame apparatus. The ley, when prepared, is to be added to the oil and tallow in the boiler at intervals, ſimilar to thoſe in making the hard ſoap, and the ſtirring kept up in the ſame way, till the maſs aſſumes a proper conſiſtency. The experienced ſoap-maker will judge, when the materials are in proper proportions, by the appearance of the ſoap when boiling; hence he knows when to ceaſe to add more ley. Should a ſtranger to the proceſs of making either kind of ſoap have to perform the taſk, he would require to know the proportions in which the alkali ought to bear to the oil. He would weigh his oil or tallow when he put it into the boiler; he will aſſay his ley by the method laid down in the commencement of this article, and by that means know how much real alkali is contained in a given meaſure of his ley. He will by this means know nearly when he had added a ſufficient quantity of ley to ſaturate the oil or fat. In the ſoap made with ſoda, the real alkali muſt be to the oil as 1 to 7.28, and that with all potaſh muſt be as 1 to 5.1 nearly. This of courſe will be the proportion for ſoft ſoap. When the ſoft ſoap is of a proper conſiſtency for caking, it is poured into barrels, in which it is ſold.

Soaps, particularly the hard, are frequently reduced in their value, by the fraudulent practice of keeping them wet. The common or proper ſtate is when they contain about 30 *per cent.* of water; but they may, by a nefarious management, be made to contain 60 *per cent.* which is a great impoſition. This fraud, like many others, is detected when it is too late. It is found to loſe weight rapidly by expoſure to the air.

Before we cloſe this article, we may point out ſome means of economizing the uſe of the alkali in ſoap-making, which, in very extenſive manufactories, is worth attending to. In the firſt place, it ſhould be obſerved, that the ſpent leys always contain free alkali, and it is generally added a ſecond time, in order that as much as poſſible of it may be taken up. It is found, however, by experience, that ſome will ſtill be found in ſolution, which the fat will never take up. This is owing to the ſame liquid containing ſeveral neutral ſalts in ſolution. If this liquor be evaporated to a certain extent, and ſet to cool in ſhallow veſſels, the neutral ſalts will cryſtallize and ſeparate from the liquid to a certain extent. The liquid part may then be evaporated a ſecond time, and again cryſtallized. The liquid, after theſe ſalts have been ſeparated, may now be added to the fat, and the alkali will combine with it. If barilla or kelp is the alkali, then the liquid ought to have a little lime added, which evaporating, ſerves to take the carbonic acid from the ſoda. Without this precaution the carbonate of ſoda would cryſtallize with the other ſalts. With potaſh this precaution is unneceſſary.

The ſalts which are ſeparated from barilla and kelp are chiefly muriate and ſulphate of ſoda. The former may be uſed as a ſubſtitute for ſalt in the laſt part of the proceſs of boiling. The ſulphate of ſoda may be fuſed with ſawduſt or powdered coal in a reverberatory-furnace. The ſulphuret of ſoda is produced, from which the alkali may be recovered. Perfumed ſoaps are eaſily formed by adding the different eſſential oils while the ſoap is in a liquid form, but not while very hot, becauſe the perfume would evaporate. The ſaponaceous liquid, called milk of roſes, is formed by mixing the liquid obtained by expoſing potaſh to the air with roſe-water, and then adding this to oil of almonds, till the mixture becomes milky without being greaſy.

Ball Soap, commonly uſed in the North, is made with lees from aſhes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a ſort of ſaline matter (the very ſtrength or eſſence of the ley); to this the tallow is put, and the copper is kept boiling and ſtirring for above half an hour, in which time the ſoap is made; and then it is put out of the copper into tubs, or baſkets, with ſheets in them, and immediately (whilſt ſoft) made into balls. Note, it requires nearly twenty-four hours, in this proceſs, to boil away the watery part of the ley.

The ſimpleſt, and upon the whole the moſt beautiful, ſoap, is the fine white ſoap prepared from olive-oil and ſoda, extracted from the beſt barilla, which is manufactured largely in the countries where the olive grows; particularly in the ſouth of France, for which Marſeilles is the moſt celebrated, in ſome parts of Italy, and in Tripoli. A ſimilar, but more expenſive ſoap, is made of ſoda and oil of almonds for medicinal purpoſes. (See Sapo *Amygdalinus.*) What is called in our country "Windſor ſoap" is of this kind, prepared with either of the above-mentioned oils. Common ſoap is manufactured principally by our ſoap-boilers from tallow or any other fat; and the alkali employed is either barilla or pearl-aſh, or a mixture of the two, according to the price and the practice of the manufacturer. But in order to obtain a ſtiff ſalt, recourſe is had to the action of common ſalt, as we have already mentioned. The olive-oil, or Marſeilles and other ſoaps, are ſometimes artificially "marbled," or ſtreaked throughout their whole ſubſtance with red or blue veins. This ſoap is harder than the white ſoap of the ſame materials, becauſe it requires to be dried to a greater degree in order to take the marbling. This is performed, by adding to the ſoap, as ſoon as it is completely made and ſeparated from the ſpent ley, a freſh quantity of ley, and immediately afterwards a ſolution of ſulphate of iron. A decompoſition between the two takes place, and a black oxyd of iron is ſeparated, which is entangled within the liquid ſoap. The boiler is then cooled, and the ley which ſettles is drawn off; after which the ſoap is again melted. A workman then ſtands over the boiler, and ſtirs the ſoap with a wooden inſtrument, while another throws in at intervals a quantity of colcothar, or brown-red oxyd of iron, ground up with water into an uniform liquid. This diffuſes both the oxyds through the ſoap, which is then cooled and framed. This proceſs requires ſome manual dexterity, ſo that the ingredients may be ſtirred together, and the marbling ſufficiently diffuſed through the whole maſs, without mixing it completely.

Soap is much uſed in waſhing and whitening linens, cleanſing woollen cloths from oil, whitening ſilk, and freeing it from the reſinous varniſh with which it is naturally covered; and for various other purpoſes, by the dyers, perfumers, hatters, fullers, &c.

The alkaline lixiviums, being capable of diſſolving oils more effectually than ſoap, might be employed for the ſame purpoſes; but when this activity is not mitigated by oil, as it is in ſoap, they are capable of altering, and even deſtroying entirely, by their cauſticity, moſt ſubſtances, eſpecially animal matters, as ſilk, wool, and others; whereas ſoap cleanſes from oil almoſt as effectually as pure alkali, without danger of altering or deſtroying, which renders it very uſeful.

The manufacture of ſoap in London, firſt began in the year 1524; before which time this city was ſerved with white ſoap from foreign countries, and with grey ſoap, ſpeckled with white, from Briſtol, and ſold for a penny a pound, and alſo black ſoap for a halfpenny the pound.

Soap, in the *Materia Medica.* Soaps, both hard and ſoft, have been applied to medical uſe. Well made hard ſoap, fit for medical uſe, has very little odour, and a nauſeous alkaleſcent taſte; is white, and of a firm conſiſtence; does not feel greaſy, and is devoid of any ſaline effloreſcence on the ſurface. With water it forms a milky opaque ſolution; and with alcohol a nearly tranſparent, ſomewhat gelatinous, ſolution. It is decompoſed by all the acids, and by many neutral ſalts, which combine with the alkali and form new compounds; hence hard water which contains ſulphate of lime does not properly diſſolve ſoap. According to the experiments of Darcet, Lelievre, and Pelletier, (ſtated in the preceding article,) 100 parts of newly made ſoap conſiſt of 60.94 oil, 8.56 alkali, and 0.503 water: but part of the water is loſt by keeping, and the ſoap becomes lighter.

Hard ſoap, triturated with vegetable reſins and thick balſams, incorporates with them into a compound; ſoluble, like the ſoap itſelf, in watery liquors; hence it proves an uſeful ingredient in reſinous pills, which of themſelves are apt to paſs entire through the inteſtines, but by the admixture of ſoap become diſſoluble in the ſtomach. It renders unctuous and thick animal matters diſſoluble in like manner in aqueous fluids, and hence may be preſumed to act as a menſtruum for theſe kinds of ſubſtances in the body, that is, to attenuate viſcid juices and reſolve obſtructions: ſuch, in effect, are the virtues which it appears to exert in cachectic, hydropic, and icteric caſes, in which laſt, particularly, its aperient and reſolvent powers have been often experienced. Solutions of it have been likewiſe found to diſſolve certain animal concretions of the harder kind, as the filaments which are ſometimes ſeen floating in the urine of rheumatic and arthritic perſons, the matter ſecreted in gouty joints, and the more compact urinary calculus; on theſe ſubſtances (at leaſt in the latter), though ſoap of itſelf acts more languidly than lime-water, yet, when joined to that menſtruum, it remarkably increaſes its activity; the diſſolving power of a compoſition of the two being, according to Dr. Whytt's experiments, conſiderably greater than that of the ſoap and lime-water unmixed: of the good effects of theſe medicines in calculous caſes there are ſeveral inſtances; but what their effects may be in gouty and rheumatic ones is not yet well known. See Lithontriptics, Stephens's *Medicine*, &c. and Stone.

Soap is regarded, in the materia medica, as purgative and lithontriptic; externally applied it is ſtimulant and deterſive. For internal uſe the hard ſoap only is employed. It is occaſionally ordered in habitual coſtiveneſs, and in jaundice, combined with rhubarb, or ſome bitter extract; but its power as a purgative is very limited, and it cannot act in any other way in relieving jaundice. It is more uſeful in calculous habits, in which, however, its action is altogether confined to the ſtomach; for as ſoap is decompoſed by the weakeſt acids, its alkaline baſe corrects the acidity ſo prevalent in the ſtomachs of calculous patints, and thus at leaſt aſſiſts in checking the increaſe of the diſeaſe. Soap is alſo beneficial in decompoſing metallic poiſons when taken into the ſtomach; and, as it is the antidote which can moſt readily be procured, ſhould always be early reſorted to. It is neceſſary in this latter caſe to give it in ſolution; of which a teacupful ſhould be drunk at ſhort intervals, till the effects expected from it be produced. In other caſes it is preferable to give it in ſubſtance. The doſe may be from grs. v to ʒſs, made into pills.

As an external remedy, ſoap is efficaciouſly uſed in frictions to ſprains and bruiſes; and much benefit has been derived from rubbing the tumid bellies of children labouring under meſenteric fever, with a ſtrong lather of ſoap every morning and evening.

From the properties of ſoap we may know, that it muſt be a very effectual and convenient anti-acid. It abſorbs acids as powerfully as pure alkalies and abſorbent earths, without having the cauſticity of the former, and without oppreſſing the ſtomach by its weight, like the latter. Soap is alſo one of the beſt antidotes to ſtop quickly, and with the leaſt inconvenience, the bad effects of acid corroſive poiſons, as aqua fortis, corroſive ſublimate, &c.

Soap is employed externally for diſcuſſing rheumatic pains, arthritic tumours, the humours ſtagnating after ſprains, &c. Some pretend that the indurated tophaceous concretions in arthritic joints, have been reſolved by the external uſe of ſoapy cataplaſms. Several compoſitions for external purpoſes are prepared in the ſhops.

The officinal preparations of ſoap are as follow: *viz.* "Pills of ſoap with opium," of Lond. Ph.; "Pills of compound ſquill;" "Aloetic pills" of Ed. Ph.; "Pills of aloes and aſſafœtida." (See Pills.) "Pills of aloes and ginger," of the Dub. Ph. are compounded of 1 oz. of hepatic aloes, 1 dr. of ginger-root in powder, $\frac{1}{2}$ oz. of ſoap, and $\frac{1}{2}$ dr. of eſſential oil of peppermint: let the aloes and ginger be rubbed together to a powder; then add the ſoap and the oil ſo as to form a maſs. This is an uſeful pill, and uſed with advantage for obviating the habitual coſtiveneſs of the ſedentary, and of leucophlegmatic habits. The doſe is from grs. x to grs. xv, or more:— "Soap plaſter." (See Emplastrum *Saponis*, and *Soap* Plaster.) "Cerate of ſoap," of the Lond. Ph. is compoſed of 8 oz. of hard ſoap, 10 oz. of yellow wax, 1 lb. of ſemivitreous oxyd of lead powdered, a pint of olive-oil, and a gallon of vinegar. Boil the vinegar on the oxyd of lead over a ſlow fire, ſtirring diligently till they incorporate; then add the ſoap, and boil again in a ſimilar manner, until the moiſture be entirely evaporated; and, laſtly, mix with the oil the wax previouſly melted. This cerate is occaſionally uſed as a cooling dreſſing. For the "compound ſoap liniment" of the Lond. Ph. ſee Liniment. The "Tincture of ſoap," commonly called "Liniment of ſoap," of the Ed. Ph., is prepared by digeſting 4 oz. of ſoap ſliced in 2 lbs. of alcohol for three days, and then adding 2 oz. of camphor, and $\frac{1}{2}$ oz. of the volatile oil of roſemary, frequently ſhaking the mixture. Theſe preparations are ſtimulant and anodyne, and may be beneficially applied againſt local pains, and in bruiſes, rubbed upon the parts. "The tincture of ſoap and opium" of Ed. Ph., commonly called "Anodyne liniment," is made in the ſame manner, and from the ſame ingredients as the other tincture of ſoap, only adding, at the beginning of the proceſs, one ounce of opium. The addition of the opium to the ſoap liniment renders it, in many caſes of rheumatiſm and local pains, more uſeful than the ſimple liniment.

The anodyne balſam, commonly called Bates's balſam, is prepared by digeſting two ounces of ſoap and half an ounce of opium, in a gentle ſand-heat, for three days, with eighteen ounces of rectified ſpirit of wine, and then adding ſix drachms of camphor and one drachm of oil of roſemary to the ſtrained liquor. This compoſition, with the addition of opium, is ſuppoſed to be more effectual for allaying violent pains than the common opodeldoc: it is alſo given internally in nervous colics, jaundices, &c.

Soft ſoap is conſiderably more acrid than the hard ſoap, and it is, therefore, employed only for ſome external purpoſes: a mixture of equal parts of our common ſoft ſoap and quicklime is uſed as a mild cauſtic. Lewis's Mat. Med. Thomſon's Lond. Diſp.

Soap, *Almond.* See Sapo *Amygdalinus*, and Soap, *ſupra.*

Soap, *Ammoniacal*, a white ſaponaceous compound, readily made by ſhaking any oil with liquid ammonia, which is much uſed medicinally as a ſtimulating application; but the union between theſe two is much weaker than between the fixed alkalies and oil, ſo that this will not harden; and by keeping for ſome time, the ingredients will partly ſeparate. In order to effect a more intimate union between them, muriated ammonia muſt be added to common ſoap.

Soap-*Lees.* See Lixivium *Saponarium.*

The term *ſoap-lees* is ſometimes uſed technically to denote the "ſpent ley," which is pumped out of the vat or ciſtern, after the ſoap has ſeparated; and which, being more or leſs alkaline, is reſerved either to be uſed again, or to be evaporated, ſo that the reſidue may be calcined for extracting the alkali.

Soap, *Starkey's*, is a combination of fixed vegetable alkali with eſſential oil of turpentine. It is ſo called from its inventor, who combined ſalt of tartar (carbonate of potaſh) with this oil, and obtained a ſaponaceous compound, to which many medicinal virtues have been aſcribed. It enters alſo into the compoſition of pills, named alſo from Starkey. As fixed alkalies are very difficultly made to unite with eſſential oils, Starkey found no other expedient for the preparation of his ſoap, than time and patience. His method conſiſts in putting dry alkali into a matraſs, and pouring upon it eſſential oil of turpentine to a height equal to the breadth of two or three fingers: in five or ſix months part of the alkali and oil will be thus combined together, and form a ſoap, which muſt be ſeparated from the mixture, and more of it will be afterwards formed in the ſame manner. The moſt commodious method, ſays Dr. Lewis, of obtaining the combination, is by throwing the ſalt, red-hot, into a heated mortar, immediately reducing it to powder; then pouring on it, whilſt hot, by little at a time, an equal quantity, or more, of the oil, and continuing to grind them together, ſo as to form a ſmooth ſoft maſs. Stahl, Rouelle, Beaumé, &c. have publiſhed proceſſes for this combination. Mr. Beaumé ſays, that it may be made in a few hours by triturating, during a long time, alkaline ſalt upon a porphyry, and adding to this ſalt, during the trituration, oil of turpentine. This medicine, which has an acrid alkaline taſte, and is very apt to deliquiate on being expoſed to air, was formerly celebrated, under the denomination of ſoap of tartar, univerſal corrector, &c. as a diuretic in nephritic complaints, and as a corrector of certain vegetables, particularly of opium: its virtues have not been fully determined by experience, nor does the preſent practice pay any regard to it.

Soap, *Volatile*, is of three kinds, *viz.* one compoſed of fixed alkalies and volatile oils; another of volatile alkalies and oils of the groſſer or more fixed kind; and the third, in which both the alkali and the oil are volatile. Of the firſt kind is Starkey's ſoap: thoſe of the ſecond ſort are obtained more readily. (See Linimentum *Volatile*, and Epithem *Volatile.*) Combinations of the latter kind, in a liquid form, have been deſcribed under Salts; and compoſitions of the ſame kinds may be obtained in a ſolid ſtate, by mixing the ſalt with the oil, and ſubliming them together.

Soap, *Laws relating to.* By 17 Geo. III. c. 52. no perſon, within the limits of the head office of exciſe in London, ſhall be permitted to make any ſoap, unleſs he occupy a tenement of 10*l.* a year, and be aſſeſſed to, and pay the pariſh rates; or elſewhere, unleſs he be aſſeſſed to, and pay to church and poor. By 24 Geo. III. c. 41. and 43 Geo. III. c. 69. every ſoap-maker ſhall annually take out a licence, for which he ſhall pay 2*l.* By 43 Geo. III. c. 68. ſched. (A), certain duties are laid on ſoap imported, as therein ſtated; and upon the exportation of ſoap made in Great Britain, and which hath paid the duties, the ſame ſhall be drawn back, by 43 Geo. III. c. 69. ſched. (C): but no drawback ſhall be allowed on the exportation of foreign ſoap imported. (27 Geo. II. c. 21.) By 43 Geo. III. c. 69. ſched. (A), certain duties are impoſed on ſoap made in Great Britain; and certain allowances ſhall be made for ſoap uſed in the manufactures of Great Britain, ſched. (C). Places of making are to be entered on pain of 200*l.* (10 Ann. c. 19. 47 Geo. III. ſeſſ. 2. c. 30.); and covers and locks to be provided under a forfeiture of 100*l.* (5 Geo. III. c. 43. 12 Geo. III. c. 40.) The furnace-door of every utenſil uſed in the manufacture of ſoap ſhall be locked by the exciſe officer, as ſoon as the fire is damped or drawn out, and faſtenings provided; and opening or damaging ſuch faſtening incurs a penalty of 100*l.* (17 Geo. III. c. 52. 24 Geo. III. c. 48. ſeſſ. 2.) Officers are required to enter and ſurvey at all times, by day or night, and the penalty of obſtructing is 50*l.*; and they may unlock and examine every copper, &c. between the hours of five in the morning and eleven in the evening, and the penalty of obſtructing is 100*l.* No ſoap-maker ſhall have any private pipe or conveyance, on pain of 200*l.*; and the penalty of obſtructing an officer who ſearches for it is 100*l.* No maker ſhall have more than one moveable pump, on penalty of 500*l.* Every maker of ſoap, before he begins any making, if within the bills of mortality, ſhall give twelve hours, if elſewhere, twenty-four hours' notice, in writing, to the officer, of the time when he intends to begin, on pain of 100*l.* No maker ſhall remove any ſoap unſurveyed, on pain of 20*l.*, without giving proper notice of his intention. And if any maker ſhall conceal any ſoap or materials, he ſhall forfeit the ſame, and alſo 500*l.* (1 Geo. III. ſtat. 2. c. 36.) And the penalty of privately making ſoap is forfeiture of the ſoap and materials, and 100*l.* (5 Geo. III. c. 43.) Perſons aſſiſting in making ſoap privately ſhall forfeit, for the firſt offence, 20*l.*; for the ſecond, 40*l.* or be liable to four months' impriſonment till it be paid. (47 Geo. III. ſeſſ. 2. c. 30.) Owners or renters of houſes where ſoap ſhall be privately made forfeit 200*l.* Every barrel of ſoap ſhall contain 256 lbs. avoirdupois, half-barrel 128 lbs., firkin 64 lbs., half-firkin 32 lbs., beſides the weight or tare of each caſk; and all ſoap, excepting hard cake ſoap and ball ſoap, ſhall be put into ſuch caſks and no other, on pain of forfeiture and 5*l.* (10 Ann. c. 19. 12 Ann. ſt. 2. c. 9.) The maker ſhall weekly enter in writing at the next office the ſoap made by him in each week, with the weight and quantity at each boiling, on pain of 50*l.*; and within one week after entry clear off the duties, on pain of double duty. (17 Geo. III. c. 52.) Cockets granted for ſhipping ſoap to be conveyed to any other part of the kingdom, ſhall expreſs the quality, quantity, and weight, the mark of the package, by whom made and ſold, and where conſigned, under penalty of forfeiture and ſeizure of the ſame and package. (23 Geo. II. c. 21.) No ſoap ſhall be imported, otherwiſe than in ſome package, containing at leaſt 224 pounds of hard ſoap, on pain of ſeizure and forfeiture, and alſo package; and the maſter of the veſſel ſhall forfeit 50*l.* If any perſon ſhall knowingly harbour or conceal any ſoap, unlawfully imported, or relanded after ſhipping for exportation upon debenture, he ſhall forfeit 50*l.* for every hundred weight, together with the goods and package. The maker ſhall keep juſt ſcales and weights, where he makes his ſoap, and permit and aſſiſt the officer to uſe them, on pain of 10*l.* (10 Ann. c. 19.) And by 10 Geo. III. c. 44. for inſufficient ſcales and weights, he ſhall forfeit 100*l.*

Soap-*Aſhes*, in *Agriculture*, the refuſe of ſoap-boilers, ſometimes termed ſoapers' aſhes. See Ashes.

Soap *Refuſe*, the compounds of oil, tallow, and other ſubſtances, with lime and pot-aſh, which are often met with and uſed as manures. Moſt ſorts of ſoapy mixtures are found to have much effect in promoting vegetation.

Soap-ſuds, or the waſhings of this ſort which are left and thrown away from large mills and manufactories, ſuch as thoſe of the ſilk and other ſimilar kinds, are found highly beneficial as manures themſelves, or for being mixed and blended up with other matters in this intention. The farmers, in ſome places, collect them by the hogſhead, at the rate of from 6*d.* to 1*s.*, and mix them up with earthy materials, ſo as to form rich compoſts, in conſequence of their containing portions of animal matter, gum, and alkali, eſpecially when taken from ſilk works. And the common ſoap-ſuds, which are generally waſted and thrown away, are ſaid to have been found of great utility in cold moiſt meadows; and would probably be more ſo, if employed in combination

bination with rich earthy ſubſtances. All the various refuſe matters of this ſort ſhould be collected, as they are capable of being uſed in this way with advantage to the farmer. See Saline *Manures*.

Soap-*Stone*, in *Mineralogy*, a variety of ſteatite. (See Steatite.) The name is derived from the colour, and the peculiar unctuous feel, which reſembles that of white ſoap. It is ſometimes ſtriped and mottled with veins and ſpots of a dull purple. When firſt quarried it is very ſoft, and yields to the nail; but gradually grows harder by expoſure to the air, though it never loſes the ſoapy feel by which it is characterized. The only part of England where ſoap-ſtone is procured is at the promontory of the Lizard, in Cornwall: it occurs in veins in ſerpentine, to which rock it ſeems nearly allied. A large quantity of this ſtone is uſed in the china manufacture at Worceſter. Its value ariſes from its great infuſibility, and its property of preſerving its whiteneſs in the furnace. The former it derives from the abſence of lime, or the alkalies; the latter from the abſence of metallic matter, of which a very ſmall portion only can be traced by chemical analyſis. The fracture of ſoap-ſtone is uneven and ſplintery; it is tranſlucent in minute fragments; it cracks and falls to powder in hot water.

Soap-*Earth*, *Smyrna*. See Flos *Aſiæ*, Natron, and Saponacea *Terra*.

SOAPBERRY-Tree, in *Botany*. See Sapindus.

The ſkin or pulp of the berries of the ſoapberry-tree is uſed as ſoap: they are of the ſize of a muſket-ball, with winged leaves, and are uſed in waſhing without any admixture of ſalt or oil. They perform the office of ſoap very well, as to the cleanſing of the linen, but being of a very acid nature, they rot it in time.

The Negroes in general uſe them for their coarſe apparel, which bears them much better than the finer linen worn by the Europeans.

It is ſaid, that this fruit is a medicine of ſingular and ſpecific virtue in chloroſes, and that a tincture or extract is preferable to the berry in ſubſtance; whence it may be preſumed, that the ſoapy matter is diſſoluble in ſpirit. Its medicinal virtue was firſt publiſhed by Marloe, in a letter to Mr. Boyle; but it is unknown in practice, and in the ſhops. Lewis.

SOAPERS' Waste, in *Agriculture*, the waſte materials of ſoap manufactories, and of other places where works of this nature are carried on, which are uſeful as manure. Theſe waſte matters have been recommended in this intention, moſtly on the ſuppoſition, that their effects principally depended upon the different ſaline matters which they contained; but it has been found, that the quantity of ſuch ſubſtances in them is very ſmall indeed, and that it principally conſiſts of mild lime and quicklime. It is ſaid that lime, when made wet with ſalt-water, yields more of this waſte than in other caſes, and is capable of being employed as manure, in certain caſes, with greater benefit than that of lime in its ordinary ſtate. This is a material which is very extenſively made uſe of in ſome diſtricts.

SOAPEY Rock, in *Geography*, a rock in the Engliſh Channel, cloſe to the Corniſh coaſt; 4 miles N.W. of Lizard Point.

SOAPWORT, in *Botany*, &c. See Saponaria.

SOAR, or Sour, anciently *Leire*, in *Geography*, a river of England, which riſes about five miles from Lutterworth, paſſes by Leiceſter, &c. and runs into the Trent on the borders of Nottinghamſhire, about three miles N.N.E. of Kegworth.

Soar, a fort of Hindooſtan, in Bahar; 23 miles N. of Durbunga. N. lat. 26° 30′. E. long. 86° 5′.

Soar-*Hawk*. See Falcon.

SOARA, in *Ancient Geography*, a river of India, on this ſide of the Ganges. Ptolemy.

SOASTUS, a river of India, which ran into the Cophas, according to Arrian.

SOATRIS, a town of Lower Mœſia, upon the Euxine ſea, between Marcianopolis and Anchiale, according to the Itinerary of Antonine.

SOATTO. See Soaggio.

SOAVE, Ital. was a muſical term, formerly, for ſinging or playing in a ſweet and pleaſing manner; but *dolce* has long ſupplied its place; which ſee.

SOAVO, in *Geography*, a town of Italy, in the Veroneſe; 10 miles E. of Verona.

SOAY, a ſmall iſland on the coaſt of Sutherlandſhire, near the entrance of Loch Inver. It affords good paſturage for ſheep. N. lat. 56° 29′. W. long. 6° 27′.

SOB, a river of Ruſſia, which runs into the Oby; 32 miles S.W. of Obdorſkoi.

SOBALA, in *Ancient Geography*, a town of Aſia Minor, in Caria. Steph. Byz.

SOBALASSARA, a town of India, on this ſide of the Ganges, which Ptolemy attributes to the Caſpiræi.

SOBANNUS, a river of India, on this ſide of the Ganges, the mouth of which is placed by Ptolemy between Pagraſa and Pithonobaſte.

SOBATZ, in *Geography*, a town of Sclavonia, on the river Save; 30 miles W.S.W. of Belgrade.

SOBERNHEIM, a town of France, in the department of the Rhine and Moſelle; 10 miles W.S.W. of Creutznach. N. lat. 49° 45′. E. long. 7° 45′.

SOBHA, in *Hindoo Mythology*, is a perſonification of beauty, and the name of a nymph celebrated in the annals of the Eaſt for her amours with *Kriſhna*; which ſee. See alſo Radha, for the tranſlation of a paſſage wherein ſhe is mentioned.

SOBIESKI's Shield, in *Aſtronomy*. See Scutum *Sobieſki*.

SOBIESKY, in *Biography*. See John, king of Poland.

SOBIESLAU, in *Geography*, a town of Bohemia, in the circle of Bechin; 10 miles E. of Bechin. N. lat. 49° 18′. E. long. 14° 34′.

SOBINKA, a town of Bohemia, in the circle of Boleſlau; 5 miles S.W. of Jung Buntzel.

SOBOTALE, in *Ancient Geography*, a town of Arabia Felix, which, according to Pliny, was the capital of the Atramites.

SOBOTKA, in *Geography*, a town of Bohemia, in the circle of Boleſlau; 11 miles E.S.E. of Jung Buntzel. N. lat. 50° 24′. E. long. 15° 11′.

SOBRADA, a town of Spain, in Galicia; 9 miles E.S.E. of Lugo.

SOBRADILLO, a town of Spain, in the province of Leon; 24 miles N.N.W. of Civdad Rodrigo.

SOBRALIA, in *Botany*, a genus dedicated, in the *Flora Peruviana*, p. 109, to the honour of Don Francis Martin Sobral, a diſtinguiſhed Spaniſh botaniſt. *De Theis*.

SOBRARVA, in *Geography*, a diſtrict and principality of Spain, included in Aragon, W. of Ribagorga, anciently a ſmall kingdom.

SOBRE BUENA, a name given by the Spaniards in America to a ſpecies of vanilla, which is greatly ſuperior to all the other kinds.

The pods of this are of the ſame ſhape with thoſe of the common vanilla, but are nearly twice as large. A bundle of about fifty of theſe uſually weighs five ounces, and ſuch a bundle of the ſobre buena kind often weighs eight. Theſe are full of a blackiſh balſamic liquor, in which are contained a number of ſmall ſeeds.

SOBREYRA, in *Botany*, a genus named in honour of John Sobreyra, a Spaniſh monk and a naturaliſt. *De Theis.*

SOC, Sok, or *Soka*, in *Law*, denotes juriſdiction; or a power or privilege to adminiſter juſtice, and execute laws.

The word is alſo uſed for the ſhire, circuit, or territory, in which ſuch power is exerciſed by him endued with ſuch juriſdiction.

Hence, alſo, the law Latin *ſoca*, uſed for a ſeignory or lordſhip infranchiſed by the king, with liberty of holding a court of his *ſoc-men* or *ſocagers*, that is, his tenants; whoſe tenure is hence called *ſocage*.

This kind of liberty ſtill ſubſiſts in ſeveral parts of England, under the name of *ſoke* or *ſoken*. Skene defines *ſoc* to be, *ſecta de hominibus ſuis in curia ſecundum conſuetudinem regni.* Brady makes mention of theſe liberties: *ſoc, ſac, tol, team, infangthef,* and *utfangthef.*

In the laws of Henry I. *ſoca* is alſo uſed as ſynonimous with franchiſe, for a privileged place, refuge, aſylum, or ſanctuary, &c. from the Saxon *ſocn*, or *ſocne*.

SOCAGE, or Soccage, in its moſt extenſive ſignification, ſeems to denote a tenure by any certain and determinate ſervice. And thus, our ancient writers conſtantly put it in oppoſition to chivalry, or knight-ſervice, where the render was uncertain.

Thus Bracton, if a man holds by a rent in money, without any eſcuage or ſerjeanty, *id tenementum dici poteſt ſocagium.* Littleton alſo defines it to be, where the tenant holds his tenement of the lord by any *certain* ſervice in lieu of all other ſervices, ſo that they be not ſervices of chivalry, or knight-ſervice: therefore, he tells us, that whatſoever is not tenure of chivalry is tenure in ſocage. The ſervice muſt therefore be certain, in order to denominate it ſocage; as to hold by fealty and 20*s.* rent; or by homage, fealty, and 20*s.* rent; or by homage and fealty, without rent; or by fealty and certain corporal ſervices, as ploughing the lord's land for three days; or by fealty only, without any other ſervice; for all theſe are tenures in ſocage.

Socage is of two ſorts; *viz. free* ſocage, where the ſervices are not only certain but honourable; and *villein* ſocage, where the ſervices, though certain, are of a baſer nature. See Villenage.

Such as hold by the former tenure are called, in Glanvil, and other ſubſequent authors, by the name of *liberi ſokemanni*, or tenants in free ſocage. This, in the nature of its ſervice, and the fruits and conſequences appertaining to it, was always much the moſt free and independent ſpecies of any. On this account, the learned judge Blackſtone aſſents to Mr. Somner's etymology of the word; who derives it from the Saxon appellation *ſoc*, which ſignifies *liberty* or *privilege*, and, being joined to a uſual termination, is called *ſocage*, ſignifying by it a free or privileged tenure. This etymology, he ſays, ſeems to be much more juſt than that of our common lawyers in general, who derive it from *ſoca, a plough*; becauſe in ancient time their ſocage-tenure conſiſted in nothing elſe, but ſervices of huſbandry, which the tenant was bound to do to his lord, as to plough, ſow, or reap for him; but that in proceſs of time, this ſervice was changed into an annual rent by conſent of all parties, and that, in reference to its original, it ſtill retains the name of ſocage, or plough-ſervice. But this by no means agrees with what Littleton himſelf tells us, that to hold by fealty only, without paying any rent, is tenure in ſocage; for here is plainly no commutation for plough-ſervice. Beſides, even ſervices, confeſſedly of a military nature and original, the inſtant they were reduced to a certainty, changed both their name and nature, and were called ſocage. It was the *certainty*, therefore, that denominated it a ſocage-tenure; and nothing ſurely could be a greater liberty or privilege, than to have the ſervice aſcertained, and not left to the arbitrary calls of the lord, as in the tenure of chivalry. Wherefore alſo Britton, who deſcribes ſocage-tenure under the name of *fraunke ferme*, tells us, that they are lands and tenements, of which the nature of the fee is changed by feoffment *out of chivalry* for *certain* yearly ſervices, and in reſpect of which, neither homage, ward, marriage, nor relief, can be demanded. Moreover, if ſocage-tenures were of ſuch baſe and ſervile original, it is hard to account for the very great immunities, which the tenants of them always enjoyed; ſo highly ſuperior to thoſe of the tenants by chivalry, that it was thought, in the reigns of both Edward I. and Charles II. a point of the utmoſt importance and value to the tenants, to reduce the tenants by knight-ſervice to *fraunke ferme*, or tenure by ſocage. It ſeems probable, therefore, that the ſocage-tenures were the relics of Saxon liberty, retained by ſuch perſons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the ſame time more burthenſome tenure of knight-ſervice. This is peculiarly remarkable in the tenure called gavelkind, which is generally acknowledged to be a ſpecies of ſocage-tenure; the preſervation of which inviolate from the innovations of the Norman conqueror, is a fact univerſally known. And thoſe who thus preferred their liberties were ſaid to hold in *free* and *common* ſocage. This tenure will, therefore, include all other methods of holding free-lands by certain and invariable rents and duties; and, in particular, petit ſerjeanty, tenure in burgage, and gavel-kind. Blackſt. Comm. book ii. cap. 6. Lord Littleton's Hiſt. of Hen. II. vol. iii. p. 158. 8vo.

Skene defines *ſocage*, a tenure of lands, by which a man is infeoffed freely, without wardſhip and marriage, paying to his lord ſome ſmall rents, &c. which is called *free* ſocage, &c. Several diviſions of ſocage are met with in law-writers, as *ſocage in capite*, &c. But by ſtat. 12 Car. II. it is ordained, that all tenures from and after the 24th of February, 1645, ſhall be adjudged and taken for ever, to be turned into free and common ſocage.

Socage, *Guardian in*. See Guardian.

SOCAGERS, in our *Old Writers*, ſuch tenants as held by the tenure called *ſocage*. They were otherwiſe called *ſoc-men*.

SOCANDAGO, in *Geography*. See Sagendago.

SOCCELLI, among the *Romans*, were ſwaths or bands, which covered the leg down to the ſoccus.

SOCCUS, Sock, in *Antiquity*, a kind of high ſhoe, reaching above the ankle, worn by the actors in the ancient drama, in the repreſentation of comic characters.

The ſoccus was much lower than the cothurnus, and was the diſtinguiſhing wear of the comedians; as the cothurnus was of the tragedians; hence ſoccus is frequently uſed for comedy itſelf. Comedy, ſays M. Fenelon, muſt talk in a humbler ſtyle than tragedy; the ſock is lower than the buſkin.

Soccus, in *Botany*. See Artocarpus.

SOCERGA, in *Geography*, a town of Iſtria; 7 miles S.E. of Capo d'Iſtria.

SOCHAN. See ZACHAN.

SOCHATSCHOW, a town of the duchy of Warſaw; 30 miles N. of Rava.

SOCHIAVO, a town of Italy, in the Belluneſe; 5 miles W. of Belluno.

SOCHOS, in *Ancient Geography*, a town of Aſia, in Syria, ſituated on the bank of the river Singas, in the ſouthern part of the town of Samoſata.

SOCIAL WAR, in *Roman Hiſtory*, commenced A.U.C. 663, on the following occaſion. M. Livius Druſus, tribune of the people, influenced by a view to the public welfare, formed a ſcheme to reconcile all orders of men, and put an end to all diſcontents, which he foreſaw would in proceſs of time, if not removed, produce a general inſurrection. With this view he propoſed a law for inveſting the Italian allies with all the privileges of Roman citizens. They remonſtrated that they paid conſiderable taxes; that, in time of war, their countries raiſed double the number of forces that were raiſed in Rome; that the commonwealth owed greatly to their valour that prodigious power which ſhe had acquired; and that it was but juſt they ſhould ſhare the honour of a ſtate, which they had helped to aggrandize both with their arms and treaſures. But this law of Druſus in their favour was oppoſed with great violence, not only by the ſenators and knights, but even by the people, who could not bear the thoughts of making thoſe their fellow-citizens, whom they looked upon as their ſubjects. In the mean time the Italian allies flocked to Rome from all parts to ſupport their protector, and determined to effect by force what they could not gain by favour. The death of Druſus, who was baſely aſſaſſinated for attempting to procure for them the right of citizenſhip, provoked the allies to ſuch a degree, that they recurred to arms, in order to do themſelves juſtice. The Marſi, Peligni, Samnites, Campanians, and Lucanians, and in ſhort all the provinces from the Liris to the Adriatic, revolted at once. Rome had never engaged more formidable enemies. As they had all ſerved in the ſame armies of the republic, they were as well diſciplined as her legions, and their leaders had learned the art of war under her moſt famous commanders. It is ſaid of the Marſi in particular, that Rome had never gained a victory in which they had not a great ſhare. The firſt ſtep they took in their revolt, was to erect themſelves into a republic in oppoſition to that of Rome. After many alternate ſucceſſes and defeats, the conſul, Julius Cæſar, deſirous to put an end to the war, drew up a law, which was confirmed by the ſenate, and enacted, that all the nations in Italy, whoſe alliance with Rome was indiſputable, ſhould enjoy the rights of Roman citizens. This law, called the Julian law, much abated the ardour of the enemy, and drew off ſeveral nations from the confederacy. The tribune, M. Plautius Sylvanus, in conjunction with Caius Papirius Carbo, one of his colleagues, put the laſt hand to the Julian law in favour of the allies, and got it confirmed by the people, and publiſhed in the following words: all the citizens of the allied cities, who ſhall be in Italy at the time of the promulgation of this law, ſhall be deemed citizens of Rome, provided they regiſter their names with one of the three prætors within ſixty days. This brought the Italians to Rome in ſuch numbers, that the new citizens became more numerous than the old; but, leſt this ſhould make ſtrangers maſters of the elections, and conſequently of the republic, the cenſors did not incorporate them in the thirty-five Roman tribes, but formed them into new tribes, who were to vote laſt. By this means all matters were determined by a majority of voices, before the new tribes gave their ſuffrages. The allies were ſenſible of this artifice, but diſſembled their diſſatisfaction, being reſolved, when an opportunity offered, to put themſelves upon a level with the old inhabitants of Rome. The tribune, Sulpicius, propoſed a law, that all the inhabitants of Italy, who had lately obtained the right of citizenſhip, ſhould be incorporated into thirty-five tribes, and conſequently have the ſame right of voting, each in his tribe, as others had, without any diſtinction, and got it paſſed. But when Sylla prevailed, all the laws of Sulpicius were declared void and null.

SOCIETY, SOCIETAS, an aſſemblage or union of ſeveral perſons in the ſame place, for their mutual aſſiſtance, ſecurity, intereſt, or entertainment.

Societies of men united together to procure their mutual ſafety and advantage, by means of their union compoſe nations or ſtates. Men are led to aſſociate for this purpoſe by the affections and inſtincts implanted in their nature, and by the wants and weakneſſes inſeparable from the conſtitution of both their bodies and minds, and from the condition they are appointed to occupy. They alſo poſſeſs the faculties of reaſon and of ſpeech, which render them capable of mutual intercourſe for their mutual advantage. Hence we may deduce that natural ſociety which is eſtabliſhed among mankind; and the general law of this ſociety is, that each ſhould do for others whatever their neceſſities require, and they are capable of doing, without neglecting what they owe to themſelves. This law ought to be obſerved by all the individuals of the human race, in order to live agreeably to their nature, and in conformity to the deſign of their common Creator: nor can it be neglected or violated, conſiſtently with a due regard to our own ſafety and happineſs.

Thus we ſee that the univerſal ſociety of the human race is an inſtitution of nature, and that it neceſſarily reſults from the nature of man: and, therefore, all men, whatſoever be their ſtation, are obliged to cultivate and diſcharge its duties. They cannot diſpenſe with it by any convention or private aſſociation. When they unite in civil ſociety, in order to form a ſeparate ſtate, or nation, they may juſtly enter into particular engagements, towards thoſe with whom they aſſociate; but they are ſtill under the obligation of performing their duty to the reſt of the human ſpecies.

As the end of the natural ſociety eſtabliſhed between all mankind is that of their affording aſſiſtance towards their own perfection, as well as that of the ſtate; and as the nations, conſidered as ſo many free perſons who live together in a ſtate of nature, are obliged to cultivate between each other this intercourſe of humanity; the end of the great ſociety eſtabliſhed by nature between all nations is alſo a mutual aſſiſtance for the improvement of themſelves and their ſtate. Accordingly, the firſt general law which the very end of the ſociety of nations diſcovers, is, that each nation ought to contribute all in its power to the happineſs and perfection of others: but the duties which we owe to ourſelves having a claim in our preference to thoſe which are incumbent upon us with reſpect to others, a nation ought, in the firſt place, to do whatever it can to promote its own happineſs and perfection. Moreover, as nations are free and independent of each other, in the ſame manner as men are naturally free and independent, the ſecond general law of their ſociety is, that ſuch nation ought to be left in the peaceable enjoyment of that liberty which it has derived from nature. From this liberty and independence it follows, that every nation is to judge of what its conſcience demands, of what it can or cannot do, of what is proper or improper to be done; and, conſequently, to examine and determine whether it can perform any office for another, without being wanting in what it owes to itſelf. Since men are naturally equal, and their rights and obligations are the ſame, as equally proceeding from nature, nations compoſed of men conſidered as ſo many free perſons, living together in a ſtate of nature, are naturally equal, and receive from nature the ſame obligations and rights; and hence we conclude, that what is permitted to one nation is permitted to all, and what is not permitted to one is not permitted to any other. The effect of all this is the producing, at leaſt externally, and among men, a perfect equality of rights between nations, in the adminiſtration of their affairs, and the purſuit of their pretenſions, without regard to the intrinſic juſtice of their conduct, of which others have no right to form a definitive judgment; ſo that what is permitted in one is alſo permitted in the other; and they ought to be conſidered in human ſociety as having an equal right. It is, therefore, neceſſary, on many occaſions, that nations ſhould ſuffer certain things to be done that are very unjuſt and blameable in their own nature, becauſe they cannot oppoſe it by open force, without violating the liberty of ſome particular ſtate, and deſtroying the foundation of natural ſociety. The rules that flow from this principle form what Mr. Wolff calls "the voluntary law of nations." Hence it follows, that all nations have a right to repel by force what openly violates the law of the ſociety which nature has eſtabliſhed among them, or that directly attacks the welfare and ſafety of that ſociety. At the ſame time, care muſt be taken not to extend this law to the prejudice of the liberty of nations. The general and common law of nations, with reſpect to the conduct of all ſovereign ſtates, ought to be meaſured by the end of the aſſociation that ſubſiſts between them. The ſeveral engagements into which nations may enter produce a new head of the law of nations, called "conventional," or "of treaties." Beſides, certain maxims, and cuſtoms conſecrated by long uſe, and obſerved by nations between each other as a kind of law, form the "cuſtomary law of nations," or, "the cuſtom of nations." Theſe three kinds of the law of nations, "voluntary," "conventional," and "cuſtomary," together compoſe the "poſitive law of nations." For they all proceed from the volition of nations; the "voluntary law," from their preſumed conſent; the "conventional law," from an expreſs covenant; and the "cuſtomary law," from a tacit conſent. See LAW *of Nations*, STATE, and GOVERNMENT.

Of ſocieties we have a great many kinds, diſtinguiſhed by the different ends propoſed by them: *civil ſocieties, trading ſocieties, religious ſocieties, literary ſocieties*, &c.

SOCIETY, in *Trade*, is a contract or agreement between two or more perſons, by which they bind themſelves together for a certain time, and agree to ſhare equally in the profits or loſſes which ſhall accrue in the affairs for which the ſociety or copartnerſhip is contracted.

We have ſeveral very conſiderable ſocieties of this kind; as the Merchant Adventurers, the Turkey, Eaſt India, Muſcovy, Eaſtland, Greenland, Spaniſh, African, South Sea, and Hudſon's Bay, companies: the inſtitutions, policies, &c. of which, ſee under the article COMPANY.

By the Roman law, the ſocial contract needs no other ſolemnity but the ſole conſent of parties, without any writing at all; but among us, articles of copartnerſhip are required. There is no contract in which probity is more required than in ſociety; inſomuch as the laws pronounce thoſe null that are made contrary to equity, and with deſign to deceive.

The French diſtinguiſh three kinds of mercantile ſociety; *ordinary ſociety*, called alſo *collective* and *general; ſociety in commendam* or *commandity;* and *anonymous ſociety*, called alſo *momentary* and *inconnue*.

The firſt is, where ſeveral merchants act alike in the affairs of the ſociety, and do all under their collective names, which are public, and known to every body.

Society in commendam, &c. is that between two perſons, one of whom only puts his money into ſtock, without doing any other office of a copartner; the other, who is called the *complementary* of the ſociety, diſpatching all the buſineſs under his own name.

Anonymous ſociety, is that where all the members are employed, each particularly in the common intereſt, and each is accountable for profits, &c. to the reſt, but without the public's being informed of them; ſo that the ſeller has only an action againſt the particular buyer, no other name appearing.

It is alſo called *momentary*, becauſe frequently made on particular occaſions, and ceaſing with them: as in the making a purchaſe, ſelling any commodity, &c.

Of this they diſtinguiſh four kinds: *ſociety by participation*, which is uſually formed by letters from one city to another, where a merchandize is to be bought or ſold. The ſecond is, when two or three perſons go together to fairs to buy goods. The third, when two or three perſons agree to buy up the whole of ſome commodity in any country to ſell it again at their own price. And the fourth is, when three or four perſons make a journey together to buy and ſell the ſame commodity. Beſide merchants, people of quality, &c. are admitted into theſe anonymous ſocieties.

SOCIETIES, *Religious*, are parties of perſons formed either to live regularly together, or to promote the intereſt of religion, or to cultivate it in themſelves.

Of the firſt kind are all congregations of religious; particularly the Jeſuits (ſee JESUITS), who are called the ſociety of Jeſus; though they more uſually call themſelves the company of Jeſus; the ſociety of the Sorbonne; the ſociety of St. Thomas de Villeneuve, inſtituted in 1660, by F. Ange le Prouſt; the ſociety of St. Joſeph, inſtituted in 1638; the ſociety of Bretagne, a reform of Benedictines, in 1606; and the ſociety of Jeſus, a religious military order, inſtituted by Pius II.; the ſociety of the Cord. See CORD.

Of the ſecond kind are, the

SOCIETY *for the Reformation of Manners*, and putting in execution the laws againſt immorality and prophaneneſs. A ſociety of this kind was ſet on foot about the time of the Revolution, by five or ſix private perſons in London, and was afterwards exceedingly increaſed by a number of members of all denominations.

Societies for this purpoſe have been occaſionally eſtabliſhed, not only in London, but in other principal towns, in a later period.

SOCIETIES, *Friendly*. See FRIENDLY *Societies*.

SOCIETIES, *Friendly*, in reference to *Agriculture*, ſuch as are eſtabliſhed for the purpoſe of relieving the labouring claſſes during the periods of ſickneſs, or when incapable of working. Many ſocieties of this nature have been formed in different parts of the kingdom within theſe few years, with much ſucceſs. And it has been remarked by Mr. Curwen, that to encourage the people to provide means of ſupport for themſelves, in caſes of ſickneſs and misfortune, is highly deſirable, both as to the effect it produces in making them more reſpectable members of the community, and in exempting pariſhes from the moſt enormous weight of poor rates.

On this ſubject it has been ſuggeſted by a late writer, after obſerving that ſuch eſtabliſhments would certainly be attended with very beneficial conſequences, that it might be highly proper to frame a law, whereby labourers of all deſcriptions ſhould be *compelled* to aſſign a portion of the fruits of their labour, during the time of their health and ſtrength, for the eſtabliſhing of a fund for their relief when overtaken by misfortunes. The forming of provident ſocieties or clubs, by which, during the time the members are in health and the vigour of life, they may, by ſmall conſtant weekly payments, make a ſuitable proviſion, from the produce of their own induſtry, againſt the period when ſickneſs, misfortune, old age, or infirmity may reach them, is, he thinks, a meaſure which, the more it is known, the more it will meet with the approbation of the public. And though, by ſome, ſuch ſocieties may be thought very remotely, if at all, connected with the ſubject of agriculture; to the more intelligent, the beſt means of providing for the induſtrious peaſantry, whoſe 'rough laborious hand' allows the wealthy to live in indolence and eaſe, will always be an intereſting ſubject. The more ſo it muſt prove, as the ſuggeſting of proper meaſures for that effect, if attended to, will infallibly remove, in a great degree, the load of poor rates, which hangs like a mill-ſtone about the neck of the Engliſh farmer; a load which, if effectual meaſures be not in a ſhort time adopted to remove, muſt neceſſarily be attended with conſequences of the moſt alarming nature, as its weight is increaſing with ſuch rapidity, that in a few years it muſt become altogether inſupportable.

And it has been well remarked by Dr. Anderſon, that friendly ſocieties, voluntarily entered into by the induſtrious poor, have relieved many a worthy character in the time of their ſickneſs, infirmities, misfortunes, and old age, in a more ample and comfortable manner than they would have been provided for by the pariſh levies. Why, he aſks, may not all the poorer ſort in their youth be compelled to provide, out of their induſtry, for their old age and infirmities? Why may not the poor of every pariſh be by law created into friendly ſocieties? Suppoſe the maſter of every ſervant and labourer was obliged to retain, out of the wages of each, three-pence a-week, and pay the ſame in the reſpective names of ſuch ſervants and labourers into the pariſh ſtock. When a ſervant or labourer removes from one pariſh to another, he might be entitled to a certificate from the pariſh he leaves, where he has drawn no pay of the amount of the ſum total he has contributed; and when he has gained a ſettlement in another pariſh, that pariſh might be entitled to draw on the firſt for the money the pauper has paid; ſo that every man may draw his fortune after him, which may prevent many a litigation reſpecting the ſettlement of the poor, and be a great ſpur to induſtry.

In the rural economy of the weſt of England, it has been ſtated by Mr. Marſhall, that ſeveral of theſe valuable inſtitutions have exiſted in Devonſhire for about thirty years; and that their good effects are ſo evident, that the encouragement of them ought to become a national object of the firſt magnitude; not more with a view to leſſen the preſent heavy burdens of the poor rates, than to inſtil into the lower claſſes of ſociety a principle of frugality, and a ſenſe of ſocial duties, which theſe meetings, under ſuitable regulations, cannot fail of producing.

The following is the plan laid down by Mr. Pew, who has paid much attention to the ſubject, and who obſerves, that if the collection of a ſmall but voluntary tax upon the ſober and induſtrious citizen, for his own uſe when in diſtreſs, be in ſome degree beneficial, he conceives that the collection of a ſtill ſmaller, though compulſory, tax upon all ranks of men, the idle, the improvident, and the irreſolute, as well as the induſtrious citizen, for the ſame purpoſe, would be a meaſure as much more beneficial as it is more extenſive. This he conceives to be capable of being effected in this way. 1. That a proper officer be appointed for ſuch an extent of diſtrict as he may be ſuppoſed conveniently to ſuperintend, to take a liſt of the names and places of abode of all males and females above the age of ſeventeen years, in the ſame manner as the liſt is made out for the militia. 2. That every ſuch male pay two-pence *per* week, and every ſuch female three farthings or one penny *per* week, into the hands of the above officer, for the purpoſes hereafter to be ſpecified. 3. That the above officer ſhall be empowered to furniſh employment for all ſuch as are willing to work, and who cannot find it for themſelves. Whether this officer ſhould be choſen annually in rotation, after the manner of an overſeer, or whether he ſhould be a permanent officer upon an adequate ſalary, will be a matter of future conſideration; but if the latter, he ſhould be paid by the community and not out of the fund. 4. That all the poor being thus ſure of employment, the maſter or miſtreſs for whom they work ſhould be juſtified in retaining theſe ſums reſpectively out of their wages; and whether they do ſo or not, they ſhould (in default of the individual) be anſwerable to the officer for its payment. All maſters and miſtreſſes of families ſhould in like manner be anſwerable for their ſervants; and all keepers of lodgings, &c. for their inmates. 5. That theſe ſums ſhould be carried weekly to the general treaſurer of the diviſion, who ſhould give ſufficient ſecurity for the ſame. 6. That out of this fund every male who is really incapable of labour, ſhould (by virtue of a certificate from the above officer) have a right to demand from the treaſurer five ſhillings *per* week for the firſt ſix months, ſhould his illneſs laſt ſo long, and four ſhillings *per* week after that period, until he again become capable of labour. And that every female ſhould have a right to demand two ſhillings and ſix-pence *per* week for the firſt ſix months, and afterwards two ſhillings *per* week, until ſhe be again able to work: ſhe ſhould alſo be entitled to four weeks full pay at every lying-in. Every male above the age of ſixty-five years, whether capable of labour or not, ſhould be entitled to four ſhillings *per* week during life. Every female, after the ſame age, two ſhillings. 7. Any perſon having three children under nine years of age, ſhould be entitled to one ſhilling and ſix-pence *per* week, until the eldeſt ſhould have attained the age of nine years; and if he has more than three under that age, he ſhould be entitled to one ſhilling and ſix-pence *per* week for each above that number; and if any one or more of his children ſhould happen to be idiotic, inſane, or otherwiſe ſo far diſabled, either in body or mind, as to be utterly incapable of labour, each of them ſhould ſtill be conſidered as under the age of nine years, and paid for accordingly.

If a mother ſhould be left a widow, with three children under nine years of age, ſhe ſhould be entitled to receive five ſhillings; if with two children, three ſhillings; and if with one child, one ſhilling and ſix-pence *per* week; if with more than three under that age, one ſhilling *per* week for each above that number; it being admitted that all her time is taken up by three, and allowance made for it, but that ſhe is capable of looking after, and taking care of, a greater number. The wives of men ſerving in the militia, and in the army or navy, ſhould, during the abſence of their huſbands, be conſidered and provided for in all reſpects as widows.

If a child ſhould be left an orphan, under nine years of age, two ſhillings *per* week ſhould be allowed from the fund for its maintenance; if more than one of the ſame family, one ſhilling and ſix-pence *per* week for each above that number. As there is probably no leſs friendſhip amongſt the lower than amongſt the higher orders of ſociety, it would generally happen that ſome friend or relation of the deceaſed would gladly take charge of the children, provided they could do ſo without eſſential loſs to themſelves. This regulation would effectually prevent that loſs; and to compenſate in ſome degree for the want of parental affection, ſix-pence *per* week more is allowed for the maintenance of an orphan, or a family of orphans, than for a child, or a family of children, who ſtill retain their mother. If, however, any beings ſhould be ſo uncommonly unfortunate as not to be thus adopted, the officer above-mentioned ſhould be obliged to provide a receptacle for them, which he will always be able to do for the ſum or ſums above-mentioned. 8. All children above nine years of age, if in health, ſhould, if they have no parents, or their parents are not able to provide for them, be put out after the manner of pariſh apprentices. 9. All perſons neglecting or refuſing to pay their contribution, ſhould be committed to the houſe of correction for the ſpace of ————. 10. If the fund ſhould at any time fall ſhort of the neceſſary demands upon it, the deficiency ſhould be made up by a pariſh rate, collected in the ſame manner as at preſent; but without any ſenſe of obligation on the part of the multitude, (for there would be no poor,) who ſhould, in all caſes, receive their relief in the nature of a demand. 11. If the fund (as moſt probably would happen) ſhould increaſe beyond the neceſſary demands upon it, the ſurplus ſhould, on no occaſion, be diverted to any other purpoſe than the benefit of the ſubſcribers; but when the price of grain exceeded that which brings it eaſily within the reach of the multitude (ſuppoſe ſix ſhillings or ſix ſhillings and ſix-pence the Wincheſter buſhel), every perſon who had three children or more under nine years of age, ſhould have a right to demand ſuch a ſum as, in proportion to the number of his family, would reduce the various neceſſary articles of life (taking wheat as the ſtandard) to a moderate price; and, indeed, he thinks, in all caſes, when the price of grain exceeds that proportion at which the induſtrious labourer can afford to come to market, ſound policy, as well as common humanity, requires that all large families ſhould be entitled to receive ſuch a ſum as above ſpecified, although it ſhould be neceſſary to collect a rate for the purpoſe.

He need not perhaps add, that every officer intruſted with money ſhould give ample ſecurity for his integrity, and the faithful diſcharge of his duty; that due checks ſhould be eſtabliſhed to prevent embezzlement; and that all accounts ſhould be made up and balanced ſo frequently as to prevent the probability of miſtakes. And ſtill more effectually to ſecure the complete execution of the plan, it would perhaps be neceſſary to appoint a general inſpector of the funds, who, with the aſſiſtance of a few ſubordinate officers, would probably be able to attend the whole kingdom.

And it is ſuppoſed by Mr. Donaldſon, that if this plan was carried into execution by the legiſlature, it muſt in its conſequences promote eſſentially the well-being of the great body of the people, as well as the intereſts of thoſe concerned in the commerce, manufactures, and agriculture of the country. But though the eſtabliſhment of friendly or provident ſocieties has, in numerous inſtances, been found productive of the moſt ſalutary effects; and would, if well ſupported and countenanced in every part of the kingdom by the contributions of the rich proprietors, render compulſory acts of parliament unneceſſary; yet as ſuch a mode, however deſirable, could probably never be generally adopted, it would certainly be the moſt effectual method to have an act of parliament for the purpoſe framed on the above principles: without this or ſome ſimilar regulation, ſuch ſocieties will probably never, he thinks, become ſufficiently general to fully anſwer the intention. The great beneficial effects that have reſulted from theſe ſocieties, in thoſe inſtances in which they have been eſtabliſhed in pariſhes, have been ſhewn in various ſtatements of them, and ſhould promote their adoption in others, which may eaſily be done by the principal proprietors in ſuch places taking the lead in forwarding ſuch inſtitutions. In the uſe of all ſuch regulations, or thoſe of any other ſimilar kinds, they ſhould conſtantly be brought forward and well adapted to the ſtates, conditions, and circumſtances of the ſituations, places, and times, in which, and at which, they are employed, in order that the beſt effects may be produced from them.

Society *for propagating the Goſpel in foreign Parts* was inſtituted by king William III. in 1701, for ſecuring a maintenance for an orthodox clergy, and making other proviſions for the propagation of the goſpel in the plantations, colonies, factories, &c.: to that end he incorporated the archbiſhops, ſeveral biſhops, and others of the nobility, gentry, and clergy, to the number of ninety, into a body, with privilege to purchaſe two thouſand pounds a-year inheritance, and eſtates for lives or years, with other goods, to any value.

They are directed by their charter to meet yearly, on the third Friday in February, to chooſe a preſident, vice-preſident, and other officers; and the third Friday in every month, to tranſact buſineſs, depute fit perſons to take ſubſcriptions for the ſaid uſes, and of all monies ſo received to give account to the lord chancellor, &c. Of this ſociety there is a ſtanding committee at St. Paul's Chapter-houſe, who prepare matters for the monthly meeting, which is held at St. Martin's library. They are truſtees of Codrington college, in Barbadoes, ſupported by plantations in that iſland.

Society *for promoting Chriſtian Knowledge* was begun in 1699, by ſome perſons of worth, &c. Its original deſign was to propagate religion in the plantations, to ſecure the pious education of the poor at home, and to reclaim thoſe that err in the fundamentals of Chriſtianity.

In the year 1701, they had procured conſiderable charities, and had tranſmitted the ſame to the plantations, in libraries, bibles, catechiſms, &c. with a voluntary maintenance for the ſeveral miniſters to be employed in the plantations. But the ſociety for propagating the goſpel in foreign parts being then inſtituted, they were incorporated, by charter, into the ſame: and thus diſcharged, as a particular ſociety, from the farther purſuit of that branch of their original deſign, which comprehended the appointment and payment of miſſionaries, as well as the diſtribution of books; whereupon they wholly turned themſelves to the other, and became very conſiderable, by great acceſſions from among the clergy and laity.

The members of the ſociety for promoting Chriſtian knowledge meet weekly, at the ſociety's office in Bartlett's Buildings, Holborn, to concert meaſures for raiſing charity for the education of poor children, and ſetting up ſchools for that purpoſe; as alſo for the more regular diſpoſal of pious books and catechiſms, for inſtruction of the ignorant, erroneous, &c. By the aſſiſtance of members of other religious ſocieties, they have procured ſubſcriptions for the education of above three thouſand children, who are placed out in ſchools about London, and taught reading, writing, pſalmody, &c. They have diſperſed great numbers of books among the poor, in the fleet, army, &c. and have procured ſeveral to be tranſlated into Welſh, and other foreign languages, and diſperſed accordingly. This ſociety for promoting Chriſtian knowledge is ſupported excluſively by members of the church of England. They have three treaſurers,

ſurers, a ſecretary, an aſſiſtant, a clerk and collector, with two aſſiſtants.

Society, *New England*, was firſt incorporated by an ordinance of parliament in 1649, by the name of the "Preſident and Society for the Propagation of the Goſpel in New England;" and empowered to receive and diſpoſe of monies in ſuch manner as ſhould beſt conduce to the preaching and propagation of the goſpel among the natives, and for the maintenance of ſchools for the education of their children; for which purpoſe a general collection was to be made in all the counties, cities, towns, and pariſhes of England and Wales. With the ſum of money thus collected, the ſociety was enabled to purchaſe an eſtate in land of between 500*l.* and 600*l.* a year. But upon the reſtoration of king Charles II. the charter became void, and colonel Bedingfield, a papiſt, who had ſold an eſtate of 322*l. per annum*, which had been ſettled for the uſes of this ſociety, repoſſeſſed himſelf of it, and refuſed to pay back the money which he had received for it. However, the corporation being revived, in 1661, by an expreſs charter, which ordained, that there be for ever within the kingdom of England, a "Society or Company for the Propagation of the Goſpel in New England and the Parts adjacent in America," the eſtate which had been detained by Bedingfield was reſtored by the chancellor's decree. The members of this ſociety are not to exceed forty-five; theſe and their ſucceſſors, to be choſen by the ſociety, are conſtituted one body corporate, with the powers and privileges uſual in ſuch caſes: and a power is likewiſe given them to appoint commiſſioners reſiding in New England to tranſact their buſineſs in thoſe parts. The honourable Mr. Boyle was appointed by charter the firſt governor of this company. See a copy of the charter in the Appendix to Dr. Birch's Life of Mr. Boyle.

Society *of the Sons of the Clergy*, was incorporated by king Charles II. in 1678, by the name of "The Governors of the Charity for Relief of the poor Widows and Children of Clergymen." This ſociety is under the direction and management of a preſident and vice-preſident, three treaſurers, and a court of aſſiſtants compoſed of forty members. Several hundreds of widows and children of the clergy have annually received conſiderable relief from this uſeful charity. See *Corporation of the Sons of the* Clergy.

Society *of Stewards and Subſcribers for maintaining and educating poor Orphans of Clergymen till of Age to be put Apprentice*, an eſtabliſhment formed in the year 1749, which has attained a conſiderable degree of proſperity, and which has received into its ſchool more than 700 children of both ſexes, moſt of whom have been apprenticed or otherwiſe provided for. This ſociety was incorporated by an act of parliament in the 48th year of Geo. III., and it is under the management of a preſident, vice-preſident, treaſurer, ſecretary, and committee, elected annually, at a general meeting in February. The committee conſiſts of the principal officers, a ſecretary, and of 20 other members, any eight of whom ſhall be deemed a board, who meet every month. See Clergy.

Society *for the Sons of the Clergy of the eſtabliſhed Church of Scotland*, was inſtituted at Edinburgh in February 1790, and was conſtituted a body corporate by his majeſty's royal charter in 1792. The views of this ſociety have been limited only to the ſons of clergymen, conceiving that its funds will be thus moſt advantageouſly employed, and propoſing other plans of beneficence which ſhall alſo comprehend the daughters of the clergy, as its funds increaſe.

Society *for promoting religious Knowledge among the Poor* commenced in the year 1750, for the purpoſe of giving bibles, teſtaments, and other good books, to thoſe who moſt needed them, and who were moſt likely to improve them. This ſociety is ſupported by an annual ſubſcription of the members, together with the donations and legacies of other contributors; and each ſubſcriber is intitled to a nomination of books in turn, correſponding to the amount of his ſubſcription. The ſociety meets every month.

Society *for promoting Chriſtian Knowledge in the Highlands and Iſlands of Scotland*, was firſt begun by the aſſociation of private contributors at Edinburgh, about the year 1701; their deſign was approved and encouraged by queen Anne, who, in 1708, iſſued her royal proclamation for this purpoſe: and, in 1709, ſhe granted a patent, conſtituting a certain number of the ſubſcribers a ſociety, or body politic, with full powers to receive donations and purchaſe lands, &c. not exceeding 2000*l.* a year, and with the profits of the ſame to erect and maintain ſchools, &c. Accordingly the lords of ſeſſion, under her majeſty's commiſſion, nominated eighty-two ſubſcribers to be the firſt members of this ſociety, who choſe a preſident, treaſurer, ſecretary, and other officers. They alſo choſe a committee of fifteen, who were to meet every month, or oftener, as occaſion required. There is a general meeting of the whole ſociety every three months, when they admit members, make general regulations, give orders to the committee, and ſettle their accounts. In 1710 the ſociety began to ſettle ſchools. In 1738 the king granted a new patent, to cauſe ſuch children as were found proper to be inſtructed in huſbandry, houſewifery, and manufactures; in purſuance of which the ſociety erected ſeveral working ſchools. The ſociety's firſt charter extends to popiſh and infidel countries beyond the ſeas, and four miſſionaries have been maintained for converting the native Indians in America to the Chriſtian faith. The ſociety has ſeveral correſponding members in London, who meet every quarter, to receive ſubſcriptions, donations, &c. Theſe form the Correſponding Board, which was eſtabliſhed in the year 1729; and which, after remaining long inactive, began, in 1773, to co-operate more cordially with their brethren in Scotland. Since that period an annual ſermon has been preached in commendation of the charity; and the preachers have been ſelected from various religious denominations with advantage to the charity.

There is alſo a charitable ſociety in London, correſponding with the incorporated ſociety in Dublin, for promoting the Engliſh Proteſtant charter-ſchools in Ireland; under the management of a treaſurer, a ſtanding committee of fifteen, and ſecretary, who meet once a month.

Society *for promoting Chriſtianity among the Jews, London*, was inſtituted in Auguſt 1808, and it has been conducted under the management of a committee, conſiſting of eighteen members, beſides the treaſurer and ſecretary, five of whom are a quorum; who meet on the firſt Friday in every month at the Jews' chapel in Spitalfields. The object of this ſociety being to relieve the temporal diſtreſſes of the Jews, as well as to promote their ſpiritual welfare, the committee are empowered, from time to time, to adopt ſuch meaſures for any ſuch purpoſes as the majority of the members preſent may approve. General meetings are held twice in the year, for receiving the reports of the committee; and two collection ſermons are preached at each of the half-yearly meetings, for the benefit of the ſociety, one in the eſtabliſhed church, and the other among the Diſſenters. A ſermon is addreſſed to the Jews every Lord's day evening, and a regular courſe of lectures is delivered every Wedneſday evening. Divine ſervice is performed in the morning and afternoon of every Sunday.

Society *for promoting the Diſcovery of the interior Parts of Africa.* See African *Aſſociation* and Africa.

Of the third kind are divers religious ſocieties, very properly ſo called: theſe were firſt ſet on foot in London about the year 1678, by a few young men, who agreed to meet weekly, for prayer, pſalmody, and ſpiritual conference. Theſe afterwards increaſed to forty diſtinct bodies, who ſet up public prayers in many churches where they were not before frequent, procured frequent adminiſtrations of the ſacrament, and maintained lectures on that ſubject, in one church or another, almoſt on every Sunday evening.

Society, *Marine*, was founded, principally, by the late Jonas Hanway, who convened a meeting of merchants and owners of ſhips, and propoſed their forming themſelves into a ſociety for giving clothing to landſmen and boys for the ſea-ſervice. A regular ſociety was formed, and a proper committee and other officers were appointed. By the regiſters of the ſociety it appeared, that from the 24th of July, 1756, the date of the commencement of this ſociety, to the 1ſt of February, 1772, it had clothed and fitted out 5451 men, and 6306 boys: and the total number to the 31ſt of December, 1808, amounted to 20,315 men, and 30,857 boys. By 12 Geo. III. c. 67, A.D. 1772, fifty-two governors were incorporated, from which number are appointed a preſident, ſix vice-preſidents, a treaſurer, and twenty-four (in 1808 the number was ſixty) aſſiſtants, veſted with full powers to carry the deſigns of the ſociety into execution. Boys ſerving out their apprenticeſhips at ſea, not being for a leſs time than four years, are entitled to the liberty of ſetting up and exerciſing trade or buſineſs in any place in Great Britain or Ireland. No ſuch apprentice is liable to be impreſſed into the king's ſervice till after the age of eighteen years. Seven governors conſtitute a general court, which is held four times in every year. The firſt local reſidence of this ſociety was in an office over the Royal Exchange; but it has ſince erected a convenient building in Biſhopſgate-ſtreet. Among the ornaments and decorations of this building, we may reckon the mauſoleum of the late captain Thomas Hanway, preſented to the corporation by his brother, Jonas Hanway, eſq. on the 1ſt of September, 1774. An annual ſubſcription of two guineas qualifies a governor for that year; two guineas *per annum*, paid during eight years ſucceſſively, or a donation of twelve guineas, qualifies a governor for life.

Society *of St. Patrick, Benevolent*, was eſtabliſhed on the 17th of March, 1784, by a conſiderable number of noblemen and gentlemen, either natives of Ireland or variouſly connected with it, for the purpoſe of imparting comfort to perſons of that kingdom in diſtreſs: one of their objects was the education of children born of Iriſh parents, reſiding in or near London. The duke of Kent is patron of this ſociety. The union of this ſociety with the Iriſh charitable ſociety, inſtituted in the year 1704, which continued its diſtributions till the year 1756, when it ceaſed to meet, was effected by the marquis of Buckingham and a committee, which ſettled a plan for this purpoſe. Twenty guineas conſtitute a governor for life, and three guineas an annual governor. The encouragement which this ſociety has met with has induced it to engage a piece of ground in St. George's Fields, for the purpoſe of erecting a ſuitable building by ſubſcription, where the children may by degrees be taken wholly under its own care. The ſub-committee meet every month, and the grand committee four times in the year. Its officers are, a patron, preſident, ſeven vice-preſidents, three auditors, &c. a treaſurer, phyſician, ſurgeon, and ſecretary.

Society, *Philanthropic*, commenced at a ſmall houſe on Cambridge-Heath, near Hackney; but as it proſpered, buildings have been erected in St. George's Fields, to which a chapel has been lately added. The inſtitution takes its date in the year 1788, and was formed for the prevention of crimes, and the reform of the criminal poor, by the encouragement of induſtry, and the culture of good morals among thoſe children who were training in vicious courſes, public plunder, infamy, and ruin. In December 1789, the number of wards for both ſexes under the ſociety's care was ſixty. The fund of the ſociety is employed as a manufacturing capital, the inſtruction for which will ſerve at any future time to afford the children employment when they are capable of being journeymen. The age of admiſſion is limited to the ages of ſeven and fourteen, and the children taken under the care of the ſociety are either the offspring of convicted felons, or ſuch as have themſelves been engaged in criminal practices. Thoſe of the firſt claſs are orphans; and thoſe of the ſecond claſs are ſuch as in many caſes have been guilty of offences at an age which ſaves them from legal puniſhment. Objects are admitted by the committee at its weekly meetings; and they are ſeldom taken younger than eight or nine, or older than twelve. After admiſſion, boys that have been delinquents are ſent in the firſt inſtance to the "Reform," a houſe at Bermondſey ſo called; where the ſyſtem is framed with a view to the amendment of the moral character by inſtruction: out of ſchool-hours they are ſet to pick oakum, that by remaining unemployed they may not acquire habits of idleneſs. When any of them appear, by the reports of the chaplain, to be ſufficiently reformed, they are transferred to the manufactory in St. George's Fields, and placed on the ſame footing with the reſt of the boys in that ſituation. The ſons of convicts, not having been themſelves criminal, are ſent at once to the manufactory, which contains, beſides accommodations for lodging about 100 boys, workſhops for carrying on the following trades, *viz.* printing, copper-plate printing, book-binding, ſhoe-making, tailor's work, rope-making, and twine-ſpinning. The profits of the trades are carried to the account of the ſociety, a portion being appropriated, by way of reward, to ſuch of the boys as are induſtrious, partly paid to them immediately, and partly reſerved for their uſe when they ceaſe to belong to the ſociety. The girls are placed in a building contiguous to the manufactory; but all intercourſe between them and the boys is effectually prevented by a wall of conſiderable height. The girls are brought up for menial ſervants: they make their own clothing, and ſhirts for the boys, and waſh and mend for the manufactory: beſides which, their earnings in plain work are conſiderable. When of proper age, they are placed out, at low wages, in reputable families, and receive rewards for good behaviour at the end of the firſt and third years of their ſervice, *viz.* one guinea at each period. A chapel has been erected for the convenience of their attending public worſhip.

Every general court muſt conſiſt of ſeven members at leaſt; and the committee, which conſiſts of twenty-four members, together with the principal officers, viſitors, and auditors, meet once a week, and three of them are competent to proceed to buſineſs. They appoint ſub-committees. A number of boys having ſerved a regular apprenticeſhip in the ſociety's manufactory, and received certificates of their honeſty and induſtry during the latter part of their ſervice, are now employed in town as journeymen to reſpectable maſters; and many of the girls are in ſervice, and have received the pecuniary rewards aſſigned them. The preſent officers are his royal highneſs the duke of York, preſident, twelve vice-preſidents, a treaſurer, four viſitors, three auditors,

ditors, a chaplain, reader at the chapel and ſecretary, two preachers, a phyſician, ſurgeon, apothecary, ſuperintendant, and ſteward.

Society, *Philological*, comprehends a ſchool for general inſtruction and clothing of the ſons of poor clergymen, naval and military officers, reduced tradeſmen, and mechanics. It was inſtituted in the year 1792, under the patronage of the duke of York, by Mr. Thomas Collingwood of Upper Titchfield-ſtreet, Mary-le-bone. This ſociety has adopted a plan of education more liberal than is uſually provided for in common ſchools of charitable inſtitutions. The ſchool is eſtabliſhed at Liſſon Green, Paddington. The committee, conſiſting of five members, meet every month, and a general court is held once a year. The officers are his royal highneſs the duke of York, a preſident, eleven vice-preſidents, three truſtees, a committee of twenty, a ſecretary, ſeveral maſters, a ſolicitor, phyſician, ſurgeon, apothecary, and collector.

Society, called the *African Inſtitution*, was eſtabliſhed for the important object of attempting the civilization of Africa, and of educating Africans. See *African* Institution.

Society *of Friends, for American Indian Civilization*, was inſtituted by the Friends in the year 1795, and the object of it has been proſecuted with their cuſtomary aſſiduity and perſeverance, and with ſuch ſucceſs, that the northern tribes of American Indians have been conſiderably influenced to adopt the arts of cultivation, as a prelude to their being capable of receiving the truths and bleſſings of religion. The whole fraternity of Quakers intereſt themſelves in the promotion of theſe objects.

Society, *Britiſh and Foreign Bible*. This ſociety, which has been extremely ſucceſsful in promoting the circulation of the holy ſcriptures, was eſtabliſhed in the year 1804; and almoſt as ſoon as it was embodied, lord Teignmouth became the preſident, and the biſhops of London, Durham, Saliſbury, and St. David's, with ſeveral noblemen and gentlemen of high reſpectability, accepted the office of vice-preſidents. Thus conſtituted and patronized, from the popularity of its plan, and the exertions of its conductors, it obtained a rapid eſtabliſhment in the world, and may be conſidered as poſſeſſing a larger and more efficient operation than was ever acquired by an inſtitution for charitable purpoſes to be met with on the page of hiſtory. Upon its appearance before the public, Wales and Scotland diſtinguiſhed themſelves by individual, congregational, and aſſociated contributions to its funds; and rivalled each other, and their fellow-citizens in England, by the promptitude of their ſupport. Ireland alſo joined in the work. The continent of Europe felt the impulſe which London had excited, and evinced the effects of it in local aſſociations for proſecuting the ſame common purpoſe. Aſia diſplayed a ſimilar ſpirit, and Calcutta became the ſeat of a correſponding committee, profeſſing, in the name and chiefly by the funds of the ſociety in London, to aid and encourage tranſlations of the ſcriptures into all the vernacular dialects of the Eaſt. In ſome parts of America there was a ſimilar union of Chriſtians upon kindred principles, and with the ſame object in view. Several of theſe aſſociations have been aſſiſted by voluntary donations from the Britiſh and Foreign Bible Society. "Thus," ſays the hiſtorian of this inſtitution, "the flame which was kindled in London has been propagated generally over more than three-fourths of the world, and is on its way for a ſtill more extenſive and particular diffuſion."

The ſeat and centre of this inſtitution is London: its larger component parts are to be traced in auxiliary ſocieties, formed under its encouragement, and contributory to its object and operation, in ſeveral of the moſt conſiderable towns throughout the united kingdom, in all the villages about the metropolis, and in conſpicuous ſtations throughout the other portions of the world, already enumerated. Its auxiliaries within the united kingdom are more than 150, and they comprehend ſome of the moſt important and commanding poſitions. On the continent it has three auxiliaries of great activity, and acting under very reſpectable patronage, in Stockholm, Berlin, and Baſle. Theſe ſtations, from their local ſituation, and the conveniencies with which they abound, are peculiarly favourable to the object of ſupplying the inhabitants of Europe with the ſcriptures, in their ſeveral languages. The Calcutta ſociety, conſiſting of Chriſtians of different denominations, and patronized, in a meaſure, by the exiſting government, will be able in time to furniſh bibles to the native Chriſtians, ſaid to amount to a million in number, and to produce correct verſions of the ſcriptures in the various languages of the Eaſt, and to open channels for their circulation among millions of people who have never yet heard of the divine miſſion of Jeſus Chriſt. In America the ſociety is aſſiſted in the proſecution of its object by the Bible Societies of Philadelphia, New York, Connecticut, Maſſachuſetts, New Jerſey, &c.; all produced by the example of the London ſociety, aided by its funds, and acting in avowed communication and harmony with it. "In addition to theſe regular and organized bodies, the ſociety has correſpondents of various deſcriptions in different parts of the world, actively engaged in promoting its deſigns, by diſperſing, at its expence, the ſacred oracles of divine truth to men of every nation under heaven."

In the firſt ſix years of the exiſtence of this ſociety it had iſſued from its depoſitory in London more than 325,000 copies of the ſcriptures, independently of thoſe which had been printed under its auſpices, beyond the limits of the united kingdom. In England it has printed the ſcriptures, at its own expence, in the Engliſh, Welſh, Gaelic, French, Spaniſh, Portugueſe, Italian, Dutch, Daniſh, Mohawk, Eſquimaux, Modern Greek, Manks, and native Iriſh languages. On the continent it has largely aided the printing of them in nearly twenty different languages. In Aſia it has promoted, by liberal contributions, the tranſlation and publication of them in a great variety of languages and dialects.

The object of this ſociety, which has already expended ſeveral hundred thouſand pounds, is diſtinctly and excluſively to promote, in the largeſt practicable extent, the circulation of the holy ſcriptures, without note or comment, both at home and abroad. By a fundamental law and regulation of the ſociety, the copies circulated in the language of the united kingdom are thoſe of the authorized verſion only. The conſtitution of the ſociety comprehends all denominations of Chriſtians, who profeſs to regard the holy ſcriptures as the proper ſtandard of religious truth. The members of the ſociety, be their ſubſcriptions what they may, provided they are not leſs than one guinea annually, are entitled to purchaſe bibles and teſtaments at reduced prices, to five times the amount of their annual ſubſcription. For a farther account of this ſociety, we refer our readers to its annual reports, which are now grown to the ſize of a moderate octavo volume.

Ten guineas conſtitute a member for life, and one guinea an annual member, five guineas an annual governor, and fifty pounds a governor for life. Its officers are a preſident, treaſurer, aſſiſtant ſecretary, collector, and bookſeller.

An auxiliary *Bible Society* was eſtabliſhed for the county of Surrey in 1812. Its officers are a preſident, twelve vice-preſidents, a treaſurer, and two ſecretaries.

Society, *Sunday School*, was eſtabliſhed, in 1796, for promoting free and Sunday ſchools in Wales, under the patronage of the prince of Wales. Its officers are a preſident, vice-preſident, treaſurer and vice-treaſurer, and ſecretary.

Society for promoting Sunday ſchools throughout the Britiſh dominions was inſtituted in 1785. See Schools.

Society *for the Suppreſſion of Vice,* was eſtabliſhed in Eſſex-ſtreet, in the Strand, in 1802. Its officers are a preſident, twelve vice-preſidents, a treaſurer, a ſecretary, and collector.

Society, *National,* for promoting the education of the poor in the principles of the eſtabliſhed church, in England and Wales, was inſtituted in 1811. The prince of Wales is patron, and the archbiſhop of Canterbury preſident: it has a great number of vice-preſidents, including all the biſhops, a treaſurer, and ſecretary.

Society, *Naval and Military Bible,* was inſtituted in 1780, for the purpoſe of diſtributing bibles among the ſoldiers and ſailors of the army and navy. One guinea conſtitutes a governor, and ten guineas a governor for life.

Society or *Fund for the Support of decayed Muſicians and their Families,* was eſtabliſhed in 1738, and incorporated in 1790.

This inſtitution had always been patronized by many of the firſt families in the kingdom, as honorary ſubſcribers; and the public in general eagerly attended the annual benefits, which, with the ſubſcriptions of the profeſſional members and gratuitous performance, produced a conſiderable ſum. But the benevolent ſpirit of the eſtabliſhment was narrowed, and inſufficient to furniſh means of comfort to the claimants already on their liſt, and conſequently precluded the augmentation of their number, till after that memorable event, the Commemoration of Handel in 1784, by which 6000*l.* were added to their fund, enabled the governors to enlarge and extend their bounty, by a more conſiderable allowance to the decayed claimants and their families already on their liſt, and to be leſs ſcrupulous in the admiſſion of new members.

Their majeſties and the royal family having been graciouſly pleaſed to countenance this eſtabliſhment, and honour it with their preſence, not only at all the commemoration performances, but at every ſubſequent annual benefit for its ſupport, increaſed its importance, and excited an ambition in the members to be under the immediate protection of his majeſty; which wiſh was moſt graciouſly complied with in 1790, by a permiſſion to incorporate themſelves under the title of the "Royal Society of Muſicians," till which period the inſtitution went under the title of "The Fund for the Support of decayed Muſicians and their Families."

Society *for bettering the Condition of the Poor,* was founded in 1796. Its object was to examine the cauſe of individual diſtreſs, to remove difficulties in the way of parochial relief, to facilitate the diſtribution of charitable benefactors, to inſpect workhouſes and charitable inſtitutions, in order to ſuggeſt improvements, and ſo aid the important cauſe of religious inſtruction to the mature and to the young.

Society *for aboliſhing the Method of ſweeping Chimnies by climbing Boys,* was inſtituted in 1802. Ten guineas conſtitute a perpetual, and one guinea an annual governor.

Society *for the Diſcharge and Relief of Perſons impriſoned for ſmall Debts,* was inſtituted in February, 1772. The debts, or compoſition for them, of the perſons that are relieved muſt not exceed 10*l.*; and the aged and infirm are preferred, as well as thoſe that have the largeſt families, and others who have loſt their liberty by unavoidable misfortunes, and not by fraud, vice, or extravagance. No debtor can be relieved a ſecond time. The annual ſubſcriptions are two guineas, and thoſe for life are twenty guineas. Similar in its object is the "Philanthropic Society" at Mile-End; the annual ſubſcription being only twelve ſhillings, and five guineas conſtituting a life-governor.

Society *of Friends of Foreigners in Diſtreſs,* was inſtituted A.D. 1806, to relieve the deſtitute in a ſtrange land, by pecuniary, medical, legal, and religious aid. One guinea conſtitutes an annual governor, and ten guineas a governor for life.

Society, *Hibernian,* was inſtituted A.D. 1806, for the purpoſe of providing every poor family in Ireland with a copy of the holy ſcriptures, eſpecially of the New Teſtament, to increaſe the number of their Sunday ſchools, to circulate religious tracts, and to give encouragement to preachers of approved characters. One guinea conſtitutes an annual member, and ten guineas a member for life.

Society, *Royal Humane,* was eſtabliſhed A.D. 1774, by Dr. Cogan and Dr. Hawes, for the recovery of the apparently dead by drowning, or by any other cauſes of ſuffocation. One guinea conſtitutes an annual member, and ten guineas a member for life. See Drowning.

Society *for teaching the indigent Blind.* See Blindness.

Society *for the Relief and Inſtruction of the Deaf and Dumb.* See Deafness.

Society *for the Eſtabliſhment of a literary Fund* was inſtituted A.D. 1790, for the relief of authors in diſtreſs, whoſe claims, ſtated in writing to the committee, are duly conſidered by them, and admitted, if proper, at their diſcretion, whilſt the names of the applicants are not diſcloſed. The annual ſubſcription is one guinea, and that for life is ten guineas. The ſociety's houſe is in Gerard-ſtreet, Soho.

Society *for the Relief of Widows and Orphans of Medical Men in London and its Vicinity,* grants to a widow, provided that her income does not exceed 30*l.*, and if ſhe has children, they have not more than 10*l. per annum* each, an annuity, and a ſum towards an apprentice fee when the children are fourteen years of age. Any orphan whoſe father was a member of the ſociety at his death, who has not more than 15*l. per annum,* alſo receives an annuity; and relief is granted to medical men themſelves, rendered incapable of attending to their buſineſs. Twenty guineas conſtitute a member for life, and one guinea an annual ſubſcriber; and a ſubſcriber of two guineas for fifteen years becomes afterwards a governor.

Society *for Relief and Support of diſabled Seamen, their Widows and Children, in the Merchant Seamen's Service,* was incorporated by ſtatute 20 Geo. II. to provide relief by penſions for ſeamen incapable of future ſervice by ſickneſs, wounds, or old age, and for the widows and children of thoſe that have been killed or wounded, provided they be under fifteen years of age, or, above that age, incapable of earning a ſubſiſtence by ſome infirmity. Relief is reſtricted to thoſe who have contributed 6*d. per* month out of his wages to this fund. Fifty pounds conſtitute a governor. The affairs of the ſociety are conducted at the merchant ſeamen's office, Royal Exchange, London.

Society, *Miſſionary,* was inſtituted in the year 1795, for the purpoſe of ſpreading the goſpel in foreign parts.

Society *for Miſſions to Africa and the Eaſt,* was eſtabliſhed by voluntary ſubſcription in the year 1799, for the converſion of the African and Eaſtern tribes. The miſſionaries fixed their ſtation at Sierra Leone, alſo on the Rio Pongas and Baſſia, where they have opened ſchools, and worſhip on the Lord's day; and as the ſlave-trade declines, or is aboliſhed, they flatter themſelves with ſucceſs. Many

Maroons and others are ſaid to have been converted, children baptized, and the civilization of the heathens, and their converſion to Chriſtianity, which muſt ever concur, are effected. The annual ſubſcription is one guinea, and a life-ſubſcription twenty guineas.

Society, *Naval Charitable*, was eſtabliſhed in 1791, for the relief of indigent orphans, widows, and children of ſea-officers, and alſo ſea-officers reduced by misfortunes to indigence. A *modus* has been ſettled for the ſubſcription; *viz.* by admirals 3*l.* 3*s.*, vice-admirals 2*l.* 2*s.*, rear-admirals 1*l.* 1*s.*, captains 10*s.* 6*d.*, lieutenants 5*s.*, phyſicians 10*s.*, ſurgeons 5*s.*, maſters 5*s.*, purſers 5*s.* The ſum given to each applicant is limited to 20*l.* A ſimilar charity was eſtabliſhed at the Admiralty in 1792.

Society *for the Converſion of Negroes*, was inſtituted by the zeal of the late biſhop Porteus, and was chartered in 1795 for the converſion, inſtruction, and education of the Negro ſlaves of the Britiſh Weſt India iſlands: for which purpoſe clergymen are employed as aſſiſtants to the parochial clergy there. The biſhop, highly to his honour, indulged the conſoling hope, "that the ſame beneficent ſpirit which by degrees extinguiſhed Pagan ſlavery, will alſo gradually, and without injury to any one, relieve mankind from the preſſure of this and every other ſpecies of perſonal and perpetual ſlavery." The ſubſequent *Abolition of the* Slave-trade (which ſee) has verified this expectation. The funds ariſe from the rents of eſtates veſted in the corporation of London, under decree of the court of chancery, upon the will of the honourable Robert Boyle.

Society, *Religious Tract*, began to circulate its ſmall uſeful tracts in the year 1799; and of theſe many have been tranſlated into the Daniſh, Portugueſe, French, and Spaniſh languages, and have been diſperſed amongſt the priſoners of war, and other foreigners in this country. Auxiliary ſocieties have been founded in ſeveral other countries. A donation of ten guineas conſtitutes a governor for life, and of half-a-guinea an annual governor.

Society, *Endeavour*, was inſtituted in 1794, for promoting the principles and duties of the eſtabliſhed church, by forming a library of orthodox divinity, and the diſtribution of books; the occaſional relief of indigence, with medical aſſiſtance, including midwifery, and inoculation. It is divided into two departments, *viz.* the eaſtern and the weſtern.

Society *of Schoolmaſters* was founded in 1798, in order to eſtabliſh a fund for the benefit of their widows and orphans, and for relief of ſchoolmaſters and uſhers become neceſſitous through age, infirmity, or misfortune. The fund conſiſts of joint ſtock, which conſtitutes a benefit ſociety, and the charitable fund, which is ſupported by contributions of the members of five guineas entrance money, and one guinea annually: benefactions are received from any other perſon, 21*l.* for life. The joint ſtock is ſhared among widows and children of decayed members in certain proportions, and this is diſpoſeable property: the charitable fund is employed in relieving members and their widows, educating their orphans, aſſiſting decayed ſchoolmaſters in general and their widows, and helping others who become neceſſitous.

Society called the *Scots Corporation.* See *Scots* Hospital.

Society *for rewarding Servants, Britiſh*, commenced in 1792, with a view of offering a reward for meritorious ſervice, either by a commutation of their probable future advantages for a preſent pecuniary conſideration, or by the immediate poſſeſſion of half the contingent annuity. Subſcribers of one guinea may nominate one male or female hired domeſtic ſervant, not exceeding fifty years of age, to be regiſtered for ſuch future rewards. Subſcribers of fifteen guineas have the ſame nomination. If ſervants have ſerved any ſubſcriber three years whilſt regiſtered, they will be entitled to 5*l.* *per annum*; if more than three years, 6*l.*, to be increaſed in proportion of 3*l.* for every three years' faithful ſervice to the ſame ſubſcriber during the regiſtry. In this manner debentures have been granted to 1151 ſervants.

Society *of the Stock-Exchange Fund.* See Stock-Exchange.

Society *of the Stranger's Friend* was conſtituted to relieve diſtreſs wherever it is found, and eſpecially when out of the reach of other aſſiſtance, and to give ſuch religious inſtruction as may be ſuitable to the perſons viſited at their own habitations. For this purpoſe the viſitors divide the town into diſtricts, and perſonally attend and relieve the objects of their compaſſion.

Society, *Unitarian*, was inſtituted in 1791 for promoting Chriſtian knowledge and the practice of virtue, by diſtributing books ſelected and approved by its members. The annual ſubſcription is one guinea, and ten guineas conſtitute a governor for life, who is entitled to a proportional allowance of books.

Society, *American Philoſophical*, was eſtabliſhed at Philadelphia in the year 1769, by the union of two ſocieties which had formerly ſubſiſted in that city, for promoting uſeful knowledge, under the direction of one patron, one preſident, three vice-preſidents, one treaſurer, four ſecretaries, and three curators, who are annually choſen by ballot. The ordinary meetings of this ſociety are held on the firſt and third Fridays of every month, from October to May incluſive. The ſociety was incorporated by charter 15th March, 1780, and has publiſhed ſeveral volumes of its Tranſactions, containing many ingenious papers on general literature and the ſciences, as well as reſpecting thoſe ſubjects that are peculiar to America.

A ſociety of a ſimilar kind, under the title of the "Academy of Arts and Sciences, &c." has been alſo eſtabliſhed at Boſton. See Academy.

A Royal Society of Sciences was inſtituted at Upſal about the year 1720: the meetings are monthly, and the Tranſactions are publiſhed quarterly, in 4to.

There is alſo another ſociety at Gottenburg, called the Royal Society of Sciences and Belles Lettres.

The Society of Natural Hiſtorians at Berlin was founded by Dr. Martini; in which place there is alſo a philoſophical ſociety.

The Royal Society of Gottingen was inſtituted by king George II. in 1751.

In France there have been ſeveral inſtitutions of this kind for the improvement of ſcience, recounted under Academy; ſee alſo Institute.

For other inſtitutions of a ſimilar nature, and their literary productions, ſee Academy, Journal, and Transactions.

Society, *Edinburgh, Philoſophical*, a ſociety which ſucceeded the Medical Society, and formed upon the plan of including all the different branches of natural knowledge and the antiquities of Scotland. Its riſe and progreſs towards its preſent ſtate are as follow.

In the year 1718, a literary ſociety was eſtabliſhed at Edinburgh by the learned Ruddiman and others, which, in 1731, was ſucceeded by another for the improvement of medical knowledge. In the year 1739, the celebrated Maclaurin conceived the idea of enlarging the plan of this ſociety, by extending it to ſubjects of philoſophy and literature.

rature. The inſtitution was accordingly new-modelled by a printed ſet of laws and regulations, the number of members was increaſed, and they were diſtinguiſhed from that time by the title of "The Society for improving Arts and Sciences," or more generally by the title of "The Philoſophical Society of Edinburgh." The meetings of this ſociety, interrupted in 1745, were revived in 1752; and, in 1754, the firſt volume of their collection was publiſhed, under the title of "Eſſays or Obſervations, Phyſical and Literary," which has been ſucceeded by other volumes. This ſociety, in conſequence of the ſuggeſtion of the profeſſors of the univerſity, and particularly of the principal, the Rev. Dr. Robertſon, and the concurrence of the members of the ſociety, was incorporated by royal charter, on the 29th of March, 1783, under the name of "The Royal Society of Edinburgh," inſtituted for the advancement of learning and uſeful knowledge. The firſt meeting was held on the firſt Monday of Auguſt, 1783; when were choſen a preſident, two vice-preſidents, a ſecretary, treaſurer, and a council of twelve perſons, who are choſen by ballot annually on the laſt Monday of November, and by whom the buſineſs of the ſociety is conducted. The ſociety conſiſts of ordinary and honorary members, the latter being reſtricted to perſons reſiding out of Great Britain and Ireland. The election of new members is made at two ſtated general meetings, held on the fourth Monday of January, and the fourth Monday of June. A candidate for the place of an ordinary member muſt ſignify, by a letter addreſſed to one of the members, his wiſh to be received into the ſociety; and he muſt then be publicly propoſed at leaſt a month before the day of election. If the propoſal be ſeconded by two of the members preſent, his name is to be inſerted in the liſt of candidates, and hung up in the ordinary place of meeting. The election is made by ballot, and is determined in favour of a candidate, if he ſhall have the votes of two-thirds of thoſe preſent, in a meeting conſiſting of at leaſt twenty-one members.

The members are divided into two claſſes, which meet and deliberate ſeparately: one of theſe claſſes is denominated the "Phyſical claſs," and comprehends within its department the ſciences of mathematics, natural philoſophy, chemiſtry, medicine, natural hiſtory, and whatever relates to the improvement of arts and manufactures. The other, denominated the "Literary claſs," has for its department literature, philology, hiſtory, antiquities, and ſpeculative philoſophy. Each of the claſſes has four preſidents and two ſecretaries, who officiate by turns. At the meetings of theſe claſſes the written eſſays and obſervations of the members of the ſociety, or their correſpondents, are read publicly, and become the ſubjects of converſation. The ordinary members, who uſually reſide in the city of Edinburgh or its vicinity, are expected to attend regularly the monthly meetings, and are required to defray, by an annual contribution, the current expences of the inſtitution. The members who reſide at ſuch a diſtance from Edinburgh, that they cannot enjoy the advantages ariſing from a regular attendance on the meetings of the ſociety, are not ſubjected to any contribution for defraying its expences, but have a right to attend thoſe meetings when they are occaſionally in Edinburgh, and to take part in all their proceedings. This ſociety has publiſhed ſeveral volumes of its Tranſactions, bearing ample teſtimony to the learning and ingenious reſearches and obſervations of their various authors.

SOCIETY, *Royal*. See ROYAL *Society*.

There is alſo an Experimental Society at Dublin, for promoting natural knowledge, which was inſtituted in 1777; the members meet once every week, and diſtribute three honorary gold medals annually for the moſt approved diſcovery, invention, or eſſay, on any mathematical or philoſophical ſubject. The ſociety is under the direction of a preſident, two vice-preſidents, and a ſecretary.

A Literary and Philoſophical Society, of conſiderable reputation, has been lately eſtabliſhed at Mancheſter, under the direction of two preſidents, four vice-preſidents, and two ſecretaries. The number of members is limited to fifty; beſides whom there are ſeveral honorary members, all of whom are elected by ballot; and the officers are choſen annually in April. Several valuable eſſays have been already read at the meetings of this ſociety, and ſeveral volumes have been publiſhed.

SOCIETY *of Antiquaries*. See ANTIQUARY.

SOCIETY *for the Encouragement of Arts, Manufactures, and Commerce*, was inſtituted in the year 1754, in purſuance of a plan formed in 1753, for the purpoſe of exciting emulation and induſtry in the improvement of ingenious and commercial arts, the various branches of agriculture, &c. by honourable and pecuniary rewards. It was ſet on foot by lord Folkſtone, lord Romney, Mr. Shipley, Dr. Hales, and a few other gentlemen; but its importance and utility ſoon gained a very conſiderable acceſſion of members and ſubſcribers. This ſociety, according to its preſent conſtitution, is under the direction and management of one preſident, ſixteen vice-preſidents, the chairmen of the ſeveral committees of accounts, correſpondence, polite arts, agriculture, manufactures, mechanics, chemiſtry, colonies, and trade; in each of which department there are two, a principal ſecretary, an aſſiſtant ſecretary, regiſter, collector, and meſſenger. The office is in the Adelphi.

Every perſon, deſiring to be a member, muſt be propoſed by ſome member at one meeting, and ballotted for at a ſucceeding meeting, and if he be choſen by two-thirds of the members preſent, he is deemed a perpetual member on payment of twenty guineas, or elſe a ſubſcribing member on payment of any yearly ſum not leſs than two guineas.

The proceedings of the ſociety are regulated by a body of rules and orders eſtabliſhed for this purpoſe; all queſtions are determined by holding up of hands or ballot, and no matter can be confirmed without the aſſent of the majority at two meetings. They invite the public in general to propoſe ſubjects for encouragement, and whatever is deemed deſerving attention is referred to the conſideration of a committee, which makes a report to the whole ſociety, where it is approved, rejected, or altered. Their premiums, which have been very extenſively beſtowed, are either ſums of money, or the ſociety's medals in gold or ſilver.

Their meetings are every Wedneſday evening, from the ſecond Wedneſday in November to the end of May, and at other times on the firſt and third Wedneſday in every month.

In the Memoirs of Agriculture, and other economical arts, by Mr. Doſſie, Bailey's machines of the Society of Arts, and the Tranſactions of the Society, of which they have publiſhed a great number of volumes, we may ſee how various, extenſive, and liberal the plan, which this ſociety has adopted and purſued.

Similar ſocieties, particularly with a view to the improvement of agriculture, have been eſtabliſhed in different parts of the kingdom.

The Society inſtituted at Bath, in the year 1777, for the encouragement of agriculture, arts, manufactures, and commerce, deſerves particular mention. The Tranſactions publiſhed by this ſociety contain many valuable experiments and obſervations, particularly relating to agriculture, which

merit

merit the attention of all agriculturaliſts and farmers in the kingdom.

Society or *Board of Agriculture*, a ſociety or board of this kind, which was eſtabliſhed at London, under the authority of government, for the purpoſe of promoting agriculture and the internal improvement of the country. It was inſtituted in or about the year 1793, and conſiſts, according to the charter of its incorporation, of a preſident, of ſuch ſeveral members, by virtue of their different offices, as are therein mentioned, and of thirty ordinary members, moſtly members of parliament: beſides which, of ſo many honorary members as they may think proper, and of ſuch a number of correſponding members, natives or foreigners, as may be neceſſary for the purpoſes of the inſtitution, the former of whom have the right of being preſent at all deliberations of the ſociety, but not the latter. Neither of them, however, have the power of voting upon any queſtion.

The preſident, and a part of the ordinary members, to the number of five, may and are capable of being changed annually on the twenty-fifth day of March. The four vice-preſidents may likewiſe be annually changed, and new ones named and appointed at the ſame time, as well as the treaſurer, and ſecretary. But the under ſecretary, the clerk or clerks, with the ſurveyors, &c. are not ſubject to annual change.

It cannot be doubted or diſputed, that the plans and objects which this eſtabliſhment has in view, are extremely important, diverſified, and comprehenſive, as they relate not only to the improvement of the agriculture itſelf, but to the whole of the internal economy and management of the country. They will probably, however, be beſt underſtood by conſulting the ſmall tract, which contains an account of the origin of the eſtabliſhment and its progreſs for three years afterwards, publiſhed in 1796, by its firſt preſident, ſir John Sinclair.

The conſequence and utility of ſuch an inſtitution as this, when under judicious and able management, muſt obviouſly be very great, not only to this nation, and the community at large, but alſo in its example to others, where no ſimilar eſtabliſhments have yet taken place.

Under ſuch ſort of regulation and management, it is unqueſtionably capable of promoting improvements in many different ways, and with many different deſigns and intentions, ſo as to be of the utmoſt beneficial conſequence to the general intereſts of the country as a whole. Its means are now likewiſe much more ample and ſufficient for accompliſhing ſuch purpoſes, than they were on its firſt foundation, as they have been, in ſome meaſure, increaſed ſince that period.

It may in ſhort, by the combination of ingenuity and talent which it affords, be the means of promoting and extending a better, more full, and wider cultivation of the ſoil and territory of the country, ſomewhat in proportion to the increaſing population, wealth, luxury, and wants of the community; of collecting and embodying the numerous uſeful ſcattered facts and practices on the ſubject, which have been ſpread throughout the different diſtricts of the kingdom; and of providing and diſperſing a more full and correct body of information on all parts of the ſubject, ſo as to render the nature of the land, the objects of cultivation, and the modes of performing it, more clearly underſtood, and approach nearer to the ſtate of perfection. In theſe ways, it may alſo be the cauſe of exciting and drawing a greater and more careful attention to all matters of the agricultural kind, than has hitherto been the caſe, in all thoſe who either poſſeſs rank, property, or talents, in the different claſſes of ſociety, all through the country; which, by operating upon the vaſt maſs of knowledge that has been drawn together, muſt have the effect of giving riſe to an almoſt boundleſs variety of intereſting improvements in the profeſſion, both as a ſcience, and an uſeful practical art. Some, indeed, have been ſo much perſuaded of this, that they have indulged the notion and ſuppoſition of the inſtitution becoming of the greateſt advantage and importance to the country. Its utility and benefits muſt, however, require ſome length of time, before they can fully diſplay themſelves, as is the caſe in all ſimilar eſtabliſhments.

Societies, *County Agricultural*, the various ſocieties of this nature, which are formed and eſtabliſhed in different counties and parts of the country, for the purpoſe of improving and bettering the ſtate of the agriculture and rural management of them. Theſe kinds of ſocieties are now inſtituted in almoſt every part of the kingdom, and muſt have conſiderable effect in rendering the local modes of managing lands in ſuch ſituations more perfect and beneficial, as well as in ſpreading and diffuſing the knowledge of the improvements, which are progreſſively made in the art of cultivation, in a more full, complete, and extenſive manner. Though ſome, who are by no means deficient in intelligence or information, may have doubted of the utility and advantage of theſe inſtitutions, there can be no reaſon, on the whole, for ſuppoſing that they have not been beneficial to the intereſts of the nation. As there is probably nothing which is more conducive to general improvement, than a rational ſpirit of inquiry, inveſtigation, and experiment, the eſtabliſhment of theſe kinds of ſocieties would ſeem to have had a direct diſpoſition and tendency to excite and bring forth ſuch a ſpirit, as well as to extend it, which has been of the utmoſt advantage in guiding and directing the attentions and exertions of practical farmers to thoſe methods and objects of management, which are the moſt ſuitable and likely not only to be beneficial to themſelves, but to the whole nation and community at large.

It is not improbable, however, but by having more regard in reſpect to their regulations and the general objects of their conſideration, as well as to the various local circumſtances which are connected with them, they may be rendered a great deal more uſeful and efficient than they are at preſent, by producing a much greater competition among the ſmaller claſſes of cultivators, and by contributing to a far more exact knowledge of the nature of ſoils, the dimenſions of farms, and the real profits and benefits to be derived from them.

In ſhort, the utility and expediency of inſtitutions of this ſort muſt always be, in ſome meaſure, in proportion to the increaſe of population, and the general wants of the country, in ſo far as food is required.

Moſt of the ſocieties of this deſcription, which have been eſtabliſhed in this country, comprehend, beſides the various local regulations, which relate particularly to themſelves, the whole or a great part of the plan and objects which are compriſed in the different county reports on the ſtate of agriculture, which have been publiſhed by the Board. See Surveys of the Board of Agriculture.

Many of theſe ſocieties exiſted long before the Society or Board of Agriculture was eſtabliſhed.

Theſe ſocieties, beſides being uſeful in promoting and diſſeminating all ſorts of valuable improvements in the local rural managements and practices of the particular diſtricts to which they belong, ſuch as in fencing, draining, tilling, ploughing, ſowing, harrowing, cutting, ſecuring, watering, paſturing, ſtocking, and feeding different kinds of land or ſoil; alſo in breeding, rearing, improving, and encouraging the various ſorts of live-ſtock, in furthering planting in different modes, in bettering the tools and machinery of the art, in diſtinguiſhing and encouraging good labourers and ſervants, in regulating and ſuiting leaſes, in eſtabliſhing neceſſary and convenient fairs and markets, and in promoting any other beneficial undertakings of the ſame kind; may be highly important, and of great utility, in circulating and diffuſing more extenſively the information and inſtruction collected and brought into order by the Society or Board of Agriculture.

There are many other ways in which ſuch ſocieties may alſo contribute in benefiting the agricultural intereſts of the nation.

Society, *Horticultural, of London*, was inſtituted in 1804, under a preſident, a council, three treaſurers, and ſecretary.

Society, *Aſiatic*, an inſtitution planned by the late illuſtrious ſir William Jones, and actually formed at Calcutta, on the 15th of January, 1784, for the purpoſe of tracing the hiſtory, antiquities, arts, ſciences, and literature, of the immenſe continent of Aſia. As it was reſolved to follow as nearly as poſſible the plan of the Royal Society of London, of which the king is patron, the patronage of the Aſiatic Society was offered to the governor-general and council, as the executive power in the territories of the company. By their acceptance of this offer, Mr. Haſtings, as governor-general, appeared among the patrons of the new ſociety; "but he ſeemed in his private ſtation as the firſt liberal promoter of uſeful knowledge in Bengal, and eſpecially as the great encourager of Perſian and Shanſcrit literature, to deſerve a particular mark of diſtinction;" he was requeſted, therefore, to accept the honorary title of preſident. This was handſomely declined in a letter from Mr. Haſtings, in which he requeſted "to yield his pretenſions to the gentleman whoſe genius planned the inſtitution, and was moſt capable of conducting it to the attainment of the great and ſplendid purpoſes of its formation." On the receipt of this letter, ſir William Jones was nominated preſident of the ſociety; and we cannot give the reader a view of the object of the inſtitution in clearer language than that which he employed in his firſt diſcourſe from the chair.

"It is your deſign, I conceive (ſaid the preſident), to take an ample ſpace for your learned inveſtigations, bounding them only by the geographical limits of Aſia; ſo that, conſidering Hindooſtan as a centre, and turning your eyes in idea to the north, you have on your right many important kingdoms in the Eaſtern peninſula, the ancient and wonderful empire of China, with all her Tartarian dependencies, and that of Japan, with the cluſter of precious iſlands, in which many ſingular curioſities have too long been concealed: before you lies that prodigious chain of mountains, which formerly perhaps were a barrier againſt the violence of the ſea, and beyond them the very intereſting country of Tibet, and the vaſt regions of Tartary, from which, as from the Trojan horſe of the poets, have iſſued ſo many conſummate warriors, whoſe domain has extended at leaſt from the banks of the Ilyſſus to the mouths of the Ganges: on your left are the beautiful and celebrated provinces of Iran, or Perſia, the unmeaſured, and perhaps unmeaſurable deſerts of Arabia, and the once flouriſhing kingdom of Yemen, with the pleaſant iſles that the Arabs have ſubdued or colonized; and farther weſtward, the Aſiatic dominions of the Turkiſh ſultans, whoſe moon ſeems approaching rapidly to its wane. By this great circumference the field of your uſeful reſearches will be encloſed; but ſince Egypt had unqueſtionably an old connection with this country, if not with China, ſince the language and literature of the Abyſſinians bear a manifeſt affinity to thoſe of Aſia, ſince the Arabian arms prevailed along the African coaſt of the Mediterranean, and even erected a powerful dynaſty on the continent of Europe, you may not be diſpleaſed occaſionally to follow the ſtreams of Aſiatic learning a little beyond its natural boundary; and, if it be neceſſary or convenient that a ſhort name or epithet be given to our ſociety, in order to diſtinguiſh it in the world, that of *Aſiatic* appears both claſſical and proper, whether we conſider the place or the object of the inſtitution, and preferable to *Oriental*, which is in truth a word merely relative, and though commonly uſed in Europe, conveys no very diſtinct idea.

"If now it be aſked, What are the intended objects of our inquiries within theſe ſpacious limits? we anſwer, *Man* and *Nature*; whatever is performed by the *one*, or produced by the *other*. Human knowledge has been elegantly analyſed according to the three great faculties of the mind, *memory*, *reaſon*, and *imagination*, which we conſtantly find employed in arranging and retaining, comparing and diſtinguiſhing, combining and diverſifying, the ideas which we receive through our ſenſes, or acquire by reflection: hence the three main branches of learning are, *hiſtory*, *ſcience*, and *art*; the firſt comprehends either an account of natural productions, or the genuine records of empires and ſtates; the ſecond embraces the whole circle of pure and mixed mathematics, together with ethics and law, as far as they depend on the reaſoning faculty: and the third includes all the beauties of imagery and the charms of invention, diſplayed in modulated language, or repreſented by colour, figure, or ſound.

"Agreeably to this analyſis, you will inveſtigate whatever is rare in the ſtupendous fabric of nature, will correct the geography of Aſia by new obſervations and diſcoveries; will trace the annals and even traditions of thoſe nations who from time to time have peopled or deſolated it; and will bring to light their various forms of government, with their inſtitutions civil and religious; you will examine their improvements and methods in arithmetic and geometry; in trigonometry, menſuration, mechanics, optics, aſtronomy, and general phyſics; their ſyſtems of morality, grammar, rhetoric, and dialectic; their ſkill in chirurgery and medicine; and their advancement, whatever it may be, in anatomy and chemiſtry. To this you will add reſearches into their agriculture, manufactures, and trade; and whilſt you inquire with pleaſure into their muſic, architecture, painting, and poetry, will not neglect thoſe inferior arts by which the comforts and even elegancies of ſocial life are ſupplied or improved. You may obſerve that I have omitted their languages, the diverſity and difficulty of which are a ſad obſtacle to the progreſs of uſeful knowledge; but I have ever conſidered languages as the mere inſtruments of real learning, and think them improperly confounded with learning itſelf: the attainment of them is, however, indiſpenſably neceſſary; and if to the Perſian, Armenian, Turkiſh, and Arabic, could be added not only the Shanſcrit, the treaſures of which we may now hope to ſee unlocked, but even the Chineſe, Tartarian, Japaneſe, and the various inſular dialects, an immenſe mine would then be open, in which we might labour with equal delight and advantage."

Of this ſociety eleven volumes of the Tranſactions have been publiſhed, which are replete with information in a high degree curious and important; and we hope that the European world will ſoon be favoured with another. The much-to-be lamented death of the accompliſhed preſident may indeed damp the ſpirit of inveſtigation among the members;

bers; for to conquer difficulties ſo great as they muſt meet with, a portion ſeems to be neceſſary of that enthuſiaſm which accompanied all the purſuits of ſir William Jones; but his ſucceſſors will, we truſt, uſe their utmoſt endeavours to have the plan completed of which ſir William gave the outlines.

SOCIETY *for working Mines*, an aſſociation not long ago formed on the continent of Europe. This inſtitution originated at an accidental meeting of ſeveral mineralogiſts at Skleno, near Schemnitz, in Hungary, collected to examine a new method of amalgamation. The object of the ſociety is phyſical geography; mineralogy founded on chemiſtry; the management of ore in the different operations which it undergoes; ſubterraneous geometry; the hiſtory of mining; founderies, and the proceſſes for the extraction of the metals from the ores, either by fuſion or amalgamation, in every inſtance applied to practice. The end of this inſtitution is to collect, in the moſt extenſive ſenſe, every thing that can aſſiſt the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their reſpective countries. Each member muſt conſider himſelf as bound to ſend to the ſociety every thing which will contribute to the end of its inſtitution; to point out, with preciſion, the ſeveral facts and obſervations; to communicate every experiment which occurs, even the unſucceſsful ones, if the relation may ſeem to be advantageous to the public; to communicate to the ſociety their examination of ſchemes, and their opinions on queſtions propoſed by it; and to pay annually two ducats (about 18*s.* 6*d.*) to the direction every Eaſter. The ſociety, on the other hand, is bound to publiſh every novelty that ſhall be communicated to it; to communicate to each member, at the member's expence, the memoirs, deſigns, models, productions, and every thing connected with the inſtitution; to anſwer all the neceſſary demands made, relating in any reſpect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zellerfield, in Hartz, Brunſwick: but the ſociety is not fixed to any one ſpot: for every particular ſtate ſome practical mineralogiſt is nominated as director. Among theſe are the names of baron Born, M. Pallas, M. Charpentier, M. Prebra, and M. Henkel. Their office is to propoſe the members; to take care that the views of the ſociety are purſued in the different countries where they reſide; to anſwer the requeſts of the members of their country who are qualified to make them; in caſe of the death of a director, to chooſe another; and the majority is to determine where the archives and the ſtrong box is to be placed.

All the eminent mineralogiſts in Europe are members of this ſociety. It is erected on ſo liberal and ſo extenſive a plan, that we entertain the higheſt hopes of its ſucceſs; and have only to add, that we wiſh much to ſee the ſtudy of ſeveral other ſciences purſued in the ſame manner.

SOCIETY, *Britiſh, for extending the Fiſheries, and improving the Sea-Coaſts of this Kingdom*, was inſtituted in 1786. The end and deſign of this ſociety will beſt appear from their charter, of which we preſent an abſtract.

The preamble ſtates, "the great want of improvement in fiſheries, agriculture, and manufactures, in the Highlands and iſlands of North Britain; the prevalence of emigration, from the want of employment in thoſe parts; the proſpect of a new nurſery of ſeamen, by the eſtabliſhment of fiſhing towns and villages in that quarter. The act therefore declares, that the perſons therein named, and every other perſon or perſons who ſhall thereafter become proprietors of the joint ſtock mentioned therein, ſhall be a diſtinct and ſeparate body politic and corporate, by the name of "The Britiſh Society for extending the Fiſheries and improving the Sea-Coaſts of this Kingdom:"—that the ſaid ſociety may raiſe a capital joint ſtock, not exceeding 150,000*l.*, to be applied to purchaſing, or otherwiſe acquiring, lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fiſhing ſtations:—that the joint ſtock ſhall be divided into ſhares of 40*l.* each:—that no one perſon ſhall, in his or her name, poſſeſs more than ten ſhares, or 500*l.*:—that the ſociety ſhall not borrow any ſum or ſums of money whatſoever:—that the ſums to be advanced for this undertaking, and the profits ariſing therefrom, ſhall be divided proportionably to the ſum ſubſcribed; and that no perſon ſhall be liable for a larger ſum than he or ſhe ſhall have reſpectively ſubſcribed:—that one or two ſhares ſhall entitle to one vote and no more in perſon or by proxy, at all meetings of proprietors; three or four ſhares to two votes; five, ſix, or ſeven ſhares, to three votes; eight or nine ſhares to four votes; and ten ſhares to five votes, and no more:—that more perſons than one inclining to hold in their joint names one or more ſhares, ſhall be entitled to vote, by one of ſuch perſons, according to the priority of their names, or by proxy:—that bodies corporate ſhall vote by proxy under their ſeal:—that all perſons holding proxies ſhall be proprietors, and that no one perſon ſhall hold more than five votes by proxy:—that the affairs of the ſociety ſhall be managed by a governor, deputy-governor, and thirteen other directors, to be elected annually on the 25th of March, from among the proprietors of the ſociety, holding at leaſt one full ſhare, by ſigned liſts of their names, to be tranſmitted by the proprietors to the ſecretary of the ſociety:—that five proprietors, not being governor, director, or other officer, ſhall be in like manner annually elected to audit the accounts of the ſociety:—that there ſhall be one general meeting of the proprietors annually, on the 25th of March:—that occaſional general meetings ſhall be called, on the requeſt of nine or more proprietors:—that the general meetings of the proprietors ſhall make all bye-laws and conſtitutions for the government of the ſociety, and for the good and orderly carrying on of the buſineſs of the ſame:—that no transfer ſhall be made of the ſtock of the ſociety for three years from the 10th of Auguſt 1786:—that the caſh of the ſociety ſhall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland:—that no director, proprietor, agent, or officer of the ſociety, ſhall retain any ſum or ſums of money in his hands beyond the ſpace of thirty days, on any account whatſoever:—that all payments by the ſociety ſhall be made by drafts on the ſaid banks, under the hands of the governor or deputy-governor, counterſigned by the ſecretary or his deputy, and two or more directors:—and that the books in which the accounts of the ſociety ſhall be kept ſhall be open to all the proprietors."

The inſtitution of this public-ſpirited ſociety was in a great meaſure owing to the exertions of the patriotic John Knox; who, in the courſe of twenty-three years, traverſed and explored the Highlands of Scotland no leſs than ſixteen times, and expended ſeveral thouſand pounds of his own fortune in purſuing his patriotic deſigns.

SOCIETY, *Britiſh Wool.* See *Britiſh* WOOL *Society.*

SOCIETY, *Geological*, was inſtituted in 1811, under a preſident, four vice-preſidents, treaſurer, two ſecretaries, and a foreign ſecretary.

SOCIETY, *Mineralogical*, was inſtituted in 1799; but it is now incorporated with the former.

SOCIETY, *Entomological, of London*, inſtituted in 1806, has a preſident, vice-preſident, treaſurer, and ſecretary, ſeveral fellows, and a printer.

SOCIETY, *Linnean*, was founded in 1788, and incorporated in 1802. Its preſident is ſir James Edward Smith; it has a council, a treaſurer, ſecretary, and librarian. Its houſe is in Gerard-ſtreet, Soho. It has already (1816) publiſhed eleven volumes of its Tranſactions.

SOCIETY, *Mathematical*, in Criſpin-ſtreet, Spitalfields, was eſtabliſhed in 1717. It is under the conduct of a preſident, treaſurer, and ſecretary.

SOCIETY *for the Improvement of Naval Architecture*, was founded in 1791. The object of it is to encourage every uſeful invention and diſcovery relating to naval architecture, as far as ſhall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies, and of the reſiſtance of fluids; to procure drafts and models of different veſſels, together with calculations of their capacity, centre of gravity, tonnage, &c.; to make obſervations and experiments themſelves, and to point out ſuch obſervations and experiments as appear beſt calculated to further their deſigns, and moſt deſerving thoſe premiums which the ſociety can beſtow. But though the improvement of naval architecture in all its branches be certainly the principal object of this inſtitution, yet the ſociety do not by any means intend to confine themſelves merely to the form and ſtructure of veſſels. Every ſubordinate and collateral purſuit will claim a ſhare of the attention of the ſociety, in proportion to its merits; and whatever may have any tendency to render navigation more ſafe, ſalutary, and even pleaſant, will not be neglected.

This inſtitution owes its exiſtence to the patriotic diſpoſition and extraordinary attention of Mr. Sewell, a private citizen of London, who (though engaged in a line of buſineſs totally oppoſite to all concerns of this kind) has been led, by mere accident, to take ſuch ocular notice of, and make ſuch obſervations on, the actual ſtate of naval architecture in this country, as naturally occurred to a man of plain underſtanding, zealous for the honour and intereſt of his country, and willing to beſtow a portion of that time for the public good, which men of a different deſcription would rather have devoted to their own private advantage. His attention was the more ſeriouſly excited, by finding that it was the opinion of ſome private ſhip-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that ſuch "would ever be the caſe while that buſineſs (the conſtruction of our ſhips of war) was not ſtudied as a ſcience, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval ſchools and ſeminaries for the ſtudy of it; and that our ſhips were not a match for thoſe of that nation, either ſingly or in a fleet, &c. &c."

In a ſhort time the ſociety were enabled to offer very conſiderable premiums for particular improvements in the conſtruction of our ſhipping, &c. &c. and alſo to encourage our philoſophers, mathematicians, and mechanics, to make ſatisfactory experiments, tending to aſcertain the laws of reſiſtance of water to ſolids of different forms, in all varieties of circumſtances. On this head the reward is not leſs than 100*l.* or a gold medal. Other premiums of 50, 30, and 20 guineas, according to the importance or difficulty of the particular ſubject or point of inveſtigation, are likewiſe offered, for different diſcoveries, inventions, or improvements. The terms of admiſſion into the ſociety are a ſubſcription of two guineas annually, or twenty guineas for life.

SOCIETY *of Civil Engineers*. This ſociety took its riſe from the following circumſtances. Before or about the year 1760, a new era in all the arts and ſciences commenced in this country. Every thing which contributes to the comfort, the beauty, and the proſperity of a country, moved forward in improvement, ſo rapidly and ſo obviouſly, as to mark that period with particular diſtinction. It was about this time that manufactures were extended on a new plan, by the enterprize, the capital, and, above all, by the ſcience of the men of deep knowledge and perſevering induſtry engaged in them. It was ſeen that it would be better for eſtabliſhments to be placed in new ſituations, adapted to the obtaining raw materials, and the labour of patient and retired induſtry, than to endure the vexations that perpetually occur in corporate towns, and the wages of their extravagant workmen. This produced a new demand, not thought of till that period, in this country,—*internal navigation.* To make communications from factory to factory, and from warehouſes to harbours, as well as to carry raw materials to and from ſuch eſtabliſhments, became abſolutely neceſſary. Hence aroſe thoſe works, not of pompous and uſeleſs magnificence, but of real utility, which have been carried on to a degree of extent and magnitude, to which as yet there is no appearance of limitation.

The *ancient harbours* of this iſland, it may be ſaid, have ever been an example in the hiſtory of mankind. The ſea-ports were ſuch as nature had formed, and were but little better, notwithſtanding ſome jettees and piers of defence, which had been made and altered, without knowledge or judgment, at municipal expence. This general ſituation of things gave riſe to a new profeſſion and order of men, denominated "civil engineers." In almoſt all other poliſhed nations of Europe this was a profeſſion encouraged or inſtituted by the governments of thoſe countries, of itſelf, and by itſelf; but in this country, the formation of a body of ſuch men was left to chance; there was no public eſtabliſhment, except common ſchools, for rudimental knowledge neceſſary to all arts, naval, military, mechanical, and others.

Civil engineers, then, are a ſelf-created ſet of men, whoſe profeſſion owes its origin, not to power or influence, but to the encouragement of a great and powerful nation:—a nation become ſo from the perſevering induſtry of its manufacturing workmen, and their ſuperior knowledge in chemiſtry, mechanics, and natural philoſophy. The ſame period gave riſe to an aſſociation of a few gentlemen, of whom Mr. Smeaton was one, who propoſed that they might form themſelves into a ſociety for the advancement of the ſcience of civil engineering, and in March 1771 it was eſtabliſhed, and the members met on Friday evenings, at the Queen's Head tavern, Holborn. It did not increaſe rapidly, for in twenty years the numbers were leſs than ſeventy, and of theſe, there were only about fifteen who were real engineers, employed in public works, or private undertakings of great magnitude. The other members were either amateurs, or ingenious workmen and artificers connected with, and employed in, works of engineering. A regiſter was kept of the names of its members; and a communication of ideas and knowledge, in the particular walks of each member, were, at the ſame time, the amuſement and the buſineſs of the meetings. In this manner the ſociety proceeded till 1792, when it ceaſed to exiſt, by mutual conſent of the principal members. This diſſolution was occaſioned by the ill-treatment which Mr. Smeaton experienced from one of the members, who was under very particular obligations to him, but whoſe name is not mentioned in connection with the act of flagrant ingratitude. See ENGINEERS.

An attempt was afterwards made to rebuild the ſociety, and to place it on a better and more reſpectable foundation; but before the plan could be matured, Mr. Smeaton was no more. In April 1793, the new ſociety was, however, formed under the denomination of "The Society of Civil Engineers." It conſiſted of three claſſes: 1. Of ordinary members, to conſiſt of real engineers, actually employed as ſuch in public or in private ſervice. 2. Honorary members, to conſiſt of men of ſcience and gentlemen of rank and fortune, who had applied themſelves to ſubjects of civil engineering; and who might, for knowledge, have been real engineers, had it not been their good fortune to have it in their power to employ others in this profeſſion; and alſo of thoſe who are employed in other public ſervice, where ſuch and ſimilar kinds of knowledge are neceſſary. 3. Honorary members, conſiſting of various artiſts, whoſe profeſſions and employments are neceſſary, or extremely uſeful, as well as connected with civil engineering. The meetings of this ſociety are, we believe, ſtill held every other Friday during the ſeſſion of parliament. It may be mentioned, that the ſociety never meet without paying a juſt and natural tribute of reſpect to the memory of Mr. Smeaton, of whom we have already given a biographical article, to which may now be added the following anecdotes, communicated to the public by his daughter Mrs. Mary Dixon.

It was a maxim of this excellent man, that "the abilities of the individual are a debt due to the common ſtock of public happineſs or accommodation." This appears to have governed his actions through life: he devoted his time to the cultivation of talents by which he might benefit mankind. The arrangement of his time was governed by a method as invariable as inviolable; for profeſſional ſtudies were never broken in upon by any one; and theſe, with the exception of ſtated aſtronomical obſervations, wholly engroſſed the forenoon. His afternoons were regularly occupied by practical experiments, or ſome other branch of mechanics: and he had ſo complete a command over his thoughts, that his mind was not more entirely devoted to his profeſſion in one diviſion of time, than abſtracted from it in another. "Himſelf," ſays his daughter, "devoted to his family with an affection ſo lively, a manner at once ſo cheerful and ſerene, that it is impoſſible to ſay whether the charm of converſation, the ſimplicity of inſtruction, or the gentleneſs with which they were conveyed, moſt endeared his home. A home, in which from infancy we cannot recollect to have ſeen a trace of diſſatisfaction, or a word of aſperity to any. Yet with all this he was abſolute! and it is for caſuiſtry in education, or rule, to explain his authority; it was an authority as impoſſible to diſpute as to define."

At one period the princeſs Aſkoff, after having in vain uſed every perſuaſion to induce Mr. Smeaton to accept a *carte blanche* from the empreſs of Ruſſia, as a recompence for directing the vaſt projects which her majeſty had in view, ſaid, "Sir, you are a great man, and I honour you! You may have an equal in abilities, perhaps; but in character you ſtand ſingle. The Engliſh miniſter, ſir Robert Walpole, was miſtaken, and my ſovereign has the misfortune to know, there is one man, at leaſt, who has not his price."

Early in life Mr. Smeaton attracted the notice of the duke and ducheſs of Queenſbury, from a ſtrong reſemblance which Smeaton bore to their favourite Gay, the poet. The commencement of this acquaintance was ſingular, but the continuance of their eſteem and partiality laſted through life. Their firſt meeting was at Ranelagh, where, walking with Mrs. Smeaton, he obſerved an elderly lady and gentleman fix an evident and marked attention on him. After ſome turns they ſtopped him, and the ducheſs ſaid, "Sir, I do not know you, but ſo ſtrongly do you reſemble my poor dear Gay, we muſt be acquainted; you ſhall go home and ſup with us; and if the minds of the two men accord as much as their countenances, you will find two cheerful old folks, who can love you well, and I think you can as well deſerve it." The invitation was accepted, and as long as the duke and ducheſs lived, the friendſhip was uninterrupted. In the courſe of this, he effected the abolition of that inconſiderate indiſcriminate play among people of ſuperior rank and fortune, which compels every one to join, and at their own riſk. Mr. Smeaton deteſted cards, and his attention never following the game, he played like a child. The game was pope Joan, the general run of it was high, and the ſtake in *pope* had accidentally accumulated to a very ſerious ſum. It was Smeaton's turn by deal to double it, when, regardleſs of his cards, he buſily made ſome minutes on a ſcrap of paper, and put it on the board. The ducheſs eagerly aſked what it was; and he as coolly replied, "Your grace will recollect the field in which my houſe ſtands may be about 5 acres, 3 roods, and 7 perches, which, at 30 years' purchaſe, will be juſt my ſtake; and if your grace will make a duke of me, I preſume the winner will not diſlike my mortgage." The joke had the proper effect, and they never after played but for the mereſt trifle. See Smeaton's Reports, vol. i.

SOCIETY *of Artiſts of Great Britain*, which conſiſts of directors and fellows, was incorporated by charter in 1765, and empowered to purchaſe and hold lands, not exceeding 1000*l.* a year. The directors of this ſociety, annually elected, are to conſiſt of twenty-four perſons, including the preſident, vice-preſident, treaſurer, and ſecretary; and it is required that they be either painters, ſculptors, architects, or engravers, by profeſſion.

SOCIETY *of Engravers* was eſtabliſhed in 1802, under the patronage of the prince of Wales, a preſident, vice-preſident, treaſurer, and honorary ſecretary, &c.

SOCIETY *of Painters in Oil and Water-Colours* was eſtabliſhed in 1804, under a preſident, treaſurer, ſecretary, and committee of management.

SOCIETY *of Architects* was inſtituted in 1791; and the *Architectural Society* was formed in 1806, under a preſident, two vice-preſidents, a ſecretary, and treaſurer.

SOCIETY *for Inſurance*, &c. See ASSURANCE and INSURANCE.

SOCIETY, *Medical.* To this claſs belong ſeveral ſocieties, the principal of which in our own country are the following; *viz.* the Medical Society of London, inſtituted in the year 1752, on the plan recommended by lord Bacon (De Augm. Scient. lib. iv. cap. 2.), to revive the Hippocratic method of compoſing narratives of particular caſes, in which the nature of the diſeaſe, the manner of treating it, and the conſequences, are to be ſpecified; to attempt the cure of thoſe diſeaſes, which, in his opinion, have been too boldly pronounced incurable; and, laſtly, to extend their enquiries after the powers of particular medicines in the cure of particular caſes. The collections of this ſociety have been already publiſhed, under the title of "Medical Obſervations and Inquiries," in ſeveral volumes:—Society of Phyſicians in London, inſtituted about the year 1764, the members of which, who muſt be merely licentiates of the College of Phyſicians, are elected by ballot, and meet once a fortnight on Wedneſday evening, for the purpoſe of converſing on the prevailing diſeaſes, &c. and dine together once in a quarter:—the Medical Society in Crane-court, inſtituted in 1773, under the direction of a council, conſiſting of a preſident, treaſurer, librarian, three phyſicians, three ſurgeons, three apothecaries, and three ſecretaries: the members meet once a fortnight, on Tueſday evening, and their council is annually elected in January, when an oration is delivered by one of the members on ſome medical ſubject :—Society for the Improvement of Medical Knowledge in London, eſtabliſhed in 1782, for the purpoſe of collecting uſeful eſſays and obſervations for publication : the meetings of this ſociety are held once a fortnight, on Tueſday evening, and the members dine together once a quarter ; on which occaſion candidates for admiſſion are ballotted for : the ſociety is under the direction of a preſident, treaſurer, two ſecretaries, and a committee for reviſing and ſelecting papers for publication, who are elected annually by ballot :—the Medical Society of Edinburgh, to which the public are indebted for ſix volumes of curious and uſeful eſſays, collected principally by the late Dr. Monro, from June 1731 to June 1736 ; but this ſociety was afterwards united to another, called the Philoſophical Society :—the Medical Society of Edinburgh, incorporated by royal charter in 1778, under this title : this inſtitution appears to have been coeval with the eſtabliſhment of a regular ſchool of phyſic in the univerſity, though none of its records of an earlier date than 1737 are now preſerved : the ordinary members of this ſociety are elected by ballot, and three diſſentients exclude a candidate ; an ordinary member may alſo be elected an honorary member, who enjoys the privileges of the others, and receives a diploma, but is freed the obligation of attendance, delivering papers in rotation, &c. to which the ordinary members are ſubject ; but in this caſe the votes muſt be unanimous ; the meetings of this ſociety are held every Saturday evening, in their own hall, during the winter ſeaſon, when papers on medical ſubjects are delivered by the ſeveral members in rotation ; and four of theſe are annually elected to fill the chair in rotation, with the title of annual preſidents.

The Royal Medical Society of Paris was inſtituted in 1776. The members are divided into aſſociates ordinary, limited to thirty, honorary to twelve, extraordinary to ſixty, and foreign to ſixty, and correſpondents. This ſociety has publiſhed ſeveral volumes of Memoirs in 4to.

The Medical and Chirurgical Society of London, in Verulam Buildings, Gray's-Inn, was eſtabliſhed in 1805. Its council conſiſts of a preſident, and 15 vice-preſidents : it has a treaſurer, two ſecretaries, and a foreign ſecretary.

Society, *Philoſophical*, deſignated by the ſtyle and title of the " Royal Inſtitution," was eſtabliſhed in the year 1799, and in its charter of incorporation, ſtates that it is formed with a view " of diffuſing the knowledge and facilitating the general introduction of uſeful mechanical improvements ; and for teaching, by courſes of philoſophical lectures and experiments, the application of ſcience to the common purpoſes of life." In the execution of this plan, a ſpacious and commodious houſe was purchaſed in Albemarle-ſtreet, where convenient rooms have been prepared for the reception and public exhibition of all ſuch new mechanical inventions and improvements as ſhall be thought worthy of public notice, and proper to be publicly exhibited ; and, more eſpecially, of all ſuch contrivances as tend to increaſe the conveniencies and comforts of life, to promote domeſtic economy, to improve taſte, or to advance uſeful induſtry. Working models are provided and exhibited, of ſuch new mechanical inventions as are applicable to the common purpoſes of life. A lecture room is alſo fitted up for philoſophical lectures and experiments ; a complete laboratory and philoſophical apparatus, with the neceſſary inſtruments for making philoſophical and chemical experiments, are provided ; and men of the firſt eminence, in various branches of ſcience, are engaged for carrying into full effect this important and uſeful part of the plan. A library well furniſhed with books in various departments of literature and ſcience is alſo provided. Acceſs to the library and lectures may be had on certain conditions.

Societies of a ſimilar kind, but in a leſs perfect and ſplendid ſtate, although in ſome reſpects no leſs uſeful, are the London, Surrey, and Ruſſel inſtitutions. See the article London.

Society *of London*, *Philoſophical*, which owed its riſe and preſent flouriſhing ſtate, in a very great degree, to the active and perſevering exertions of the ingenious T. J. Pettigrew, eſq. was founded in October 1810. The *objects* of this ſociety, ſtated in its addreſs to the public, are to foſter genius, to eradicate unphiloſophical prejudice, to increaſe the knowledge of nature and of man, to deſtroy, as much as poſſible, the falſe definition of words, which has been ſo juſtly reprobated by Bacon and Locke, as the origin of ſophiſtry and miſconception ; but, above all, to remove the barrier erected by pedantry againſt univerſal knowledge, and to ſubdue an *eſprit de corps*, which has been introduced into philoſophy, tending to confine it within the narrow limits of ſects, and preventing its natural diffuſion among mankind. The *means* adopted to attain theſe objects are, firſt, to promote a literary taſte by the erection of a library common to all the members ; humbly to diffuſe more widely a familiarity with ſcience by lectures in every department of philoſophy ; and thereby to cultivate a correct mode of reaſoning, by ſubjecting thoſe lectures to a rigorous ſubſequent inveſtigation, and by introducing diſcuſſions which correſpond with the general objects of the ſociety. In this ſociety there are three claſſes of members, *viz.* ordinary, honorary, and correſponding. Every ordinary member pays at his entrance the ſum of two guineas, which ſhall be repeated annually ; he ſhall alſo ſubſcribe to the regulations of the ſociety ; and upon withdrawing himſelf forfeit all title to the property of the ſociety. No perſon ſhall be deemed eligible as an honorary member, unleſs he be author of ſome ſcientific work of celebrity, or profeſſor of ſome branch of philoſophy ; and the ſame qualifications are required in a correſponding member, except in the caſe of ſuch ordinary members, removed from town, as the council may think proper to admit. A perſon propoſed for admiſſion muſt be recommended by three members, whoſe names, together with that of the perſon nominated, ſhall be hung up in the ſociety's lecture-room fifteen days previous to his being ballotted for by the council. In ballots, three black balls ſhall be conſidered as a rejection. Each member ſhall be allowed to introduce three perſons at the ordinary meetings of the ſociety ; and he ſhall alſo be permitted to borrow books of the ſociety. The ſociety ſhall meet on every Thurſday, at eight o'clock in the evening, and a lecture ſhall be delivered at every alternate Thurſday, and the intermediate meetings ſhall be occupied in diſcuſſing the preceding lecture, or in the diſcuſſion of ſome philoſophical queſtion, which may have been ſubmitted to and approved of by the council. The ſociety ſhall meet every alternate Tueſday evening at the ſame time, to converſe on philoſophical ſubjects, or for the reading of papers previouſly preſented to and approved of by the council. In the diſcuſſions and proceedings of the ſociety, theological and political ſubjects ſhall not be admitted.

The buſineſs of the ſociety is conducted by a preſident, eight vice-preſidents, a treaſurer and ſecretary, two curators, a regiſtrar and aſſiſtant, and a council compoſed of eighteen members ; all of theſe are elected annually. The patrons of the ſociety are the dukes of Kent and Suſſex. The number of members already amounts to 200, and the library conſiſts of about 500 volumes. In both theſe reſpects the ſociety is receiving numerous acceſſions.

Society *Iſlands*, in *Geography*, a cluſter of ſix iſlands in the Pacific ocean, ſo called by captain Cook in 1769, becauſe they lie contiguous to each other, ſo that he did not think it proper to diſtinguiſh them by any other names than thoſe by which they were known to the natives; *viz.* Ulietea, Otaha, Bolabola, Huaheine, Tubai, and Maurua. See each reſpectively. They are ſituated between S. lat. 16° 10′ and 16° 55′, and between W. long. 150° 57′ and 152°. Ulietea and Otaha lie within about two miles of each other, and are both incloſed within one reef of coral rocks, ſo that there is no paſſage for ſhipping between them. This reef forms ſeveral excellent harbours; and though the entrances into them are narrow, yet a ſhip within them is exempt from all injury. The inhabitants, climate, and produce, are ſimilar, in many reſpects, to thoſe of Otaheite, from which iſland they are not above 50 leagues diſtant towards the N.W. Captain Cook ſays, "while we were employed about theſe iſlands, we expended very little of the ſhip's proviſions, and were very plentifully ſupplied with hogs, fowls, plantains, and yams, which we hoped would be of great uſe to us in our courſe to the ſouthward; but the hogs would not eat European grain of any kind, pulſe, or bread-duſt, ſo that we could not preſerve them alive; and the fowls were very ſoon ſeized with a diſeaſe that affected the head, ſo that they continued to hold it down between their legs till they died: much dependence, therefore, muſt not be placed in live-ſtock taken on board at theſe places, at leaſt not till a diſcovery is made of ſome food which the hogs will eat, and ſome remedy for the diſeaſe of the poultry."

SOCIETY-*Land*, a townſhip of America, in the ſtate of New Hampſhire and county of Hillſborough; containing 199 inhabitants.

SOCII, ALLIES, among the Romans. See ALLIANCE and SOCIAL *War*.

SOCINIANS, in *Eccleſiaſtical Hiſtory*, a ſect of Antitrinitarians, who are ſaid to have derived this denomination from the illuſtrious family of the Sozzini, which flouriſhed a long time at Sienna, in Tuſcany, and produced ſeveral great and eminent men; and, among others, Lælius and Fauſtus Socinus, who are commonly ſuppoſed to have been the founders of this ſect. Lælius was the ſon of Marianus, a famous lawyer, and diſtinguiſhed by his genius and learning, as well as by the luſtre of an unblemiſhed and virtuous conduct. Having conceived a diſguſt againſt popery, and diſapproving many doctrines of the church, he left his country in 1547; and having paſſed four years in viſiting France, England, Holland, Germany, and Poland, he at laſt fixed his reſidence at Zurich, in Switzerland, where he died in 1562, in the thirty-ſeventh year of his age. Although he adopted the Helvetic confeſſion of faith, and profeſſed himſelf a member of the church of Switzerland, he entertained doubts with reſpect to certain doctrines of religion, which he communicated to ſome learned men, whoſe judgment he reſpected, and in whoſe friendſhip he could confide. However, his ſentiments were propagated in a more public manner, after his death; as Fauſtus, his nephew and his heir, is ſuppoſed to have drawn from the papers he left behind him, that religious ſyſtem, upon which the ſect of the Socinians was founded. This Fauſtus Socinus was born at Sienna in 1539; and having continued many years in his own country, twelve of which he ſpent in the court of the grand duke of Tuſcany, he determined, in the year 1574, and the thirty-fifth of his age, to withdraw from Italy into Germany. During this period he had laboured under many diſadvantages in the purſuit of knowledge, and his ſtudies had been chiefly confined to the rudiments of logic and juriſprudence; but at Baſil, where he firſt reſided after his voluntary exile, he devoted himſelf for three years to the ſtudy of theology, under the direction and aſſiſtance of the writings of his uncle Lælius; and in 1577 he began to propagate his religious opinions without reſerve or diſguiſe. In 1578 he was invited by Blandrata, a perſon of eminence in Tranſylvania, to compoſe the commotions which were occaſioned by a party under the lead of Francis David, in the Antitrinitarian churches of that country. But failing of ſucceſs, he removed to Poland in 1579, zealouſly wiſhing to join himſelf to the Unitarian churches; but here he ſuffered many vexations, and much oppoſition, from a conſiderable number of perſons, who looked upon ſome of his tenets as highly erroneous. At length, however, he vanquiſhed the animoſity of his enemies by his gentleneſs and firmneſs, by his addreſs and eloquence, and the favour and protection of the nobility, with which he was honoured, and lived to form the Unitarians into one community, under his own ſuperintendency and direction. Having retired to a village about nine miles from Cracow, he there cloſed his life, in the year 1604; and the following epitaph was inſcribed on his tomb:

> "Tota licet Babylon deſtruxit tecta Lutherus,
> Muros Calvinus, ſed fundamenta Socinus:"

i. e. Luther deſtroyed the houſes of Babylon, Calvin the walls, but Socinus ſubverted the foundations. The ſentiments of Socinus, with regard to the principal theological ſubjects controverted among Chriſtians, will appear in the following abſtract of them from his own writings; ſome of which were publiſhed during his own life, and ſome after his death; and the collection of them, in two volumes, folio, forms part of the "Bibliotheca Fratrum Polonorum." With regard to the nature and character of Chriſt, Socinus maintained, that he was a man, conceived and formed in the womb of the Virgin, without the intervention of a man, by the power of the divine ſpirit; on this account he was, in a peculiar ſenſe, God's own and only begotten ſon, as no other perſon ever was the ſon of God in the ſame way, by the immediate origin of his being. Moreover, he was conſtituted the ſon of God by his reſurrection from the dead, and was then begotten by God, when God raiſed him from the dead. As to thoſe paſſages which have been ſuppoſed to aſſert Chriſt's exiſtence in the heavenly world, previous to his birth and appearance among men, he explains them, by alleging that Chriſt himſelf, after he was born, and before he entered on the office aſſigned him by his Father, was, in conſequence of the divine counſel and agency, in heaven, and remained there for ſome time; that he might hear from God, and being with him, as the Scripture ſays, might ſee thoſe things which he was to announce to the world, in the name of God himſelf; though he explains John, iii. 13, as figurative language. Accordingly, in explaining the firſt words of St. John's goſpel, *In the beginning was the word*, &c. he obſerves, that the terms, *in the beginning*, do not relate to eternity, but to the order of thoſe things which John was about to write concerning Jeſus Chriſt; imitating Moſes, who, in writing his hiſtory, opens his introduction with this word *beginning*, in reference to the tranſactions which he was about to record. And Jeſus is called the Word, he ſuppoſes, not on account of his nature or ſubſtance, but becauſe of the office he diſcharged when he revealed to us the word of the goſpel from the Father. *The word was with God*, *i. e.* Jeſus, as the word of God, before he was pointed out by the preaching of the Baptiſt, was known to God alone. And *the word was God:* the term God, ſays this commentator, does not denote ſubſtance, but authority, power, and beneficence, which were derived from the Father, and which entitled Chriſt, according to the opinion of this writer, to adoration and worſhip. His ideas of the efficacy of our Lord's death and mediation are utterly repugnant to thoſe that have been generally entertained by perſons called Calviniſts. Nothing, he ſays, can be more incompatible with each other, than a free pardon and ſatisfaction. He adds, no man of judgment and piety ought to entertain the idea of a ſatisfaction for ſin; ſince it plainly does very much derogate from the power and authority, or goodneſs and mercy of God; and though a propitiation be not the ſame thing as a ſatisfaction, and though God never refrained from the puniſhment of ſin, on account of any real ſatisfaction given him, yet it is certain, that in remitting the puniſhment of our ſins by Jeſus Chriſt no propitiation intervened; but God hath, from his free will, exhibited himſelf ſo propitious to us in Chriſt, as not to exact the puniſhment of our ſins, though he might juſtly have done it. However, he allows not only that the death of Chriſt, and the pouring out of his blood for us, was an offering and ſacrifice to God, but that this ſacrifice may be ſaid to have been offered up for our ſins in order to their being forgiven; yet he apprehended, that this ſacrifice, as far as it was expiatory, was offered by Chriſt, not on the croſs, but in heaven itſelf, after his reſurrection. To which purpoſe he obſerves, that Chriſt did not obtain eternal redemption for us before he entered into the holy place, and there aſſumed the prieſthood; and without a prieſthood no expiatory offering could be made.

Socinus does alſo expreſsly deny the diſtinct perſonality of the Holy Ghoſt, underſtanding by the Holy Spirit a divine energy or influence.

With reſpect to the nature and ſtate of man, Socinus thought, that the progenitor of our race was mortal, *i. e.* liable to death, by reaſon of his frame, and incapable of exemption, without an exertion of the divine favour and influence, which was not granted to him at creation; and, therefore, when the apoſtle aſſerts, that by ſin death entered into the world, he meant not natural mortality, but the neceſſity of dying, or eternal death. To this purpoſe he explains himſelf: Adam, if he had not ſinned, might have been preſerved from death by the kindneſs of God, though naturally mortal; or, if he had died, have been reſtored to life, and made immortal. By his ſin he did, as it were, refuſe to give himſelf and his poſterity this bleſſing; and, therefore, unleſs the favour of God be renewed to us, we muſt all die, and remain in the ſtate of the dead. As to the nature of the human ſoul, it ſeems to have been the opinion of Socinus, that, after this life, it doth not ſo ſubſiſt of itſelf, without the body, as to be capable of any reward or puniſhment, or any ſenſations at all. To the queſtion, whether the firſt man had any original righteouſneſs before he ſinned? Socinus replies, that if by original righteouſneſs be meant ſuch a condition that he could not ſin, this certainly was not the ſtate of Adam, as it is clear he did ſin. But if original righteouſneſs conſiſted in this, that his reaſon had the abſolute rule over his appetites and ſenſes, and invariably directed them, then the opinion of thoſe who aſcribe it to Adam is ſupported by no argument: hence it ſhould ſeem from Adam's fall, that there was no perfect harmony between them; and that his appetites and ſenſes had the dominion over his reaſon. If it be aſked, ſays Socinus, whether there is original ſin? he anſwers, this is the ſame as the inquiry, whether men, when they are born, becauſe they derive their origin from Adam, have, on account of his fall, contracted any guilt or puniſhment, or are obnoxious to either? Therefore, ſince the conſent of the will muſt conſtitute guilt, and there can be no puniſhment without antecedent guilt, it ſeems not at all poſſible that either of theſe ſhould pertain to a man when he is born, as he neither has, nor could have before, any uſe of his own will. If by original ſin be underſtood certain innate deſires, or evil concupiſcence in man, and a proneneſs to ſin, this opinion Socinus denies, and labours to refute; concluding upon the whole, that there is no ſuch thing as original ſin, *i. e.* a taint or pravity in conſequence of the ſin of the firſt man, neceſſarily produced, or by any means inflicted on the human race; and that no other evil neceſſarily flows to all his poſterity from that firſt tranſgreſſion, than by ſome means or other the neceſſity of dying; not indeed through the influence of that tranſgreſſion, but becauſe man, being naturally mortal, was on that account left by God to his own natural mortality, and what was natural became neceſſary as a puniſhment on the offender; conſequently, they who were born of him muſt be born in the ſame circumſtances, for he was deprived of nothing he naturally had or could have. From reaſoning on this ſubject, Socinus concludes, that there is a freedom of will in man, and that the powers of man are not ſo few and feeble, but that he may, with the aſſiſtance of God, obey the divine law by the right uſe and application of his powers. Divine aſſiſtance he conſiders as external and internal; and the latter, he ſays, is twofold: the one, when God by ſome means impreſſeth on the heart what he hath promiſed to them that obey him; and the other, when he inſtructs and illuminates the mind rightly to diſcern his will, in thoſe inſtances which cannot be expreſsly contained in his written word: however, this internal aſſiſtance belongs only to thoſe who have made good uſe of the external. The doctrine of predeſtination Socinus abſolutely denies, and he endeavours to account for the preſcience of the Deity, without admitting that notion of his decrees, which ſome divines have adopted. On the head of juſtification, Socinus obſerves, that God out of his mere mercy juſtifies us, *i. e.* pronounces us righteous, and grants us forgiveneſs of ſins, and eternal life; but he requireth from us, before this be done, that we believe in Chriſt, *i. e.* confide in and obey him; and our good works, or the obedience we render to Chriſt, though not the efficient or meritorious cauſe, are the *ſine qua non*, or indiſpenſable pre-requiſite of our juſtification before God, and eternal ſalvation. But if any ſhould deviate from this obedience, by falling into ſin, and continuing therein, they ceaſe to be juſtified; nevertheleſs, by repentance and amendment of life, they may be juſtified again: but this ſecond repentance, he ſays, is not in our power, God granting an ability for it to whom he pleaſeth.

Socinus denied the perpetuity of baptiſm, as an ordinance in the church, alleging that it was not preſcribed for thoſe who in any other way have publicly given their names to Chriſt, or from their earlieſt years have been educated in the Chriſtian diſcipline; or if it is to be retained in theſe days, he apprehends it ſhould be retained principally on account of thoſe who have been converted from other religions to the Chriſtian. He farther thought, that, in order to the right adminiſtration of baptiſm, it is previouſly neceſſary that the baptized perſon ſhould be a believer, and he, therefore, reckoned the practice of infant baptiſm unſcriptural and erroneous.

After this compendious abſtract of the chief theological ſentiments of Socinus, it is proper to obſerve, that, according to the uſual manner of ſpeaking, all are denominated Socinians, whoſe opinions bear a certain affinity to the ſyſtem of Socinus: but, in a ſtrict and proper ſenſe, they only are deemed the members of this ſect, who embrace wholly, or with few exceptions, the form of theological doctrine, which Socinus either drew up himſelf, or received from his uncle, and delivered to the Unitarian brethren, or Socinians, in Poland and Tranſylvania. Their ſentiments are explained at large in their Catechiſm, printed ſeveral times under the title of "Catecheſis Eccleſiarum Polonicarum, unum Deum Patrem, illiuſque Filium unigenitum, una cum Sancto Spiritu, ex ſacra Scriptura confitentium." See *Catechiſm of* Racow.

The Socinians, like other ſects diſtinguiſhed by one general denomination, are divided into ſeveral parties. Some differ from Socinus with regard to the worſhip of Chriſt; ſome deny the eternity of the future puniſhment of the wicked; and ſome apprehend it contradictory to maintain God's foreknowledge of future contingencies, &c. See Budnæans, Farnovians, and Semijudaizers.

The chief ſchool of the Socinians was at Racow, where they obtained the grant of a ſettlement, and there all their firſt books were publiſhed. But in the year 1638, in conſequence of the intemperate zeal of ſome ſtudents of the Unitarian academy in this city againſt Popery, a law was enacted at Warſaw, by which it was decreed, that the academy of Racow ſhould be deſtroyed, its profeſſors baniſhed, the printing-houſe of the Socinians deſtroyed, and their churches ſhut up. This law was immediately executed; and ſimilar edicts were enacted in other parts of Poland. In 1658 another ſevere act was publiſhed by a diet held at Warſaw, requiring all the Socinians to leave the kingdom for ever, and denouncing capital puniſhment againſt all who ſhould profeſs their opinions, or harbour their perſons. This terrible edict was renewed in 1661; and in conſequence of theſe meaſures, the Socinians ſought an aſylum among their brethren in Tranſylvania: a conſiderable number was diſperſed through the adjacent provinces of Sileſia, Brandenburgh, and Pruſſia, where their poſterity ſtill ſubſiſt. Others repaired to Holland and England. In Tranſylvania they ſtill continue numerous; and are much at their eaſe. In Holland their number is not conſiderable; and all who profeſs themſelves ſuch are by law excluded from the general toleration which prevails in that kingdom. They are called Collegians.

As to the preſent ſtate of the Socinians in Poland, a late writer obſerves, that ſince their ſuppreſſion they have had churches, which have aſſembled in private houſes, woods, or fields, as opportunity permitted; and theſe aſſemblies have been conducted under the inſpection of regular miniſters, educated at Leyden and Amſterdam. Since the edict of 1661, they have been included by the Romiſh party under the general name of Diſſidents: however, in thoſe parts of Poland, which by the late partition fell to the lot of Pruſſia, Ruſſia, or the emperor, they have now their liberty in common with their other diſſident brethren, and their public places of worſhip. The only ſociety of Socinians in England was that formed by Mr. John Biddle, under the patronage of Mr. Thomas Firmin, and his adherents were called Bidellians; but this name was loſt in the more common appellation of Socinians, or, what they preferred, Unitarians. They differed from Socinus, and the foreign Unitarians, in maintaining the perſonality of the Holy Spirit. This ſociety does not appear to have ſubſiſted after the death of Biddle; nor have the Socinians, though their ſentiments have been adopted by ſeveral, made any figure as a community in England. The moſt diſtinguiſhed Socinian writers, in Poland, were Crellius, Smalcius, Volkelius, Slichtingius, Wolzogenius, Przipcovius, and Staniſlaus Lubianicius: to this number ſome have added Grotius; and in later times we might enumerate Le Clerc, Biddle, Lardner, Lowman, Fleming, Lindſey, Prieſtley, &c. See on this ſubject Socini Oper. tom. i. and ii. paſſim. Moſheim's Eccl. Hiſt. vol. iv. p. 167, &c. 8vo. Toulmin's Life of Socinus, paſſim. See Unitarians.

SOCK. See Soccus.

Sock and *Scythe-Land*. See Husband-*Land*.

Sock, in *Agriculture*, provincially the ſhare of a plough, or that part that opens the land; but properly the iron part, or ſock, which is put upon it. They are of different kinds, as ſharp-pointed and feathered on the edge, &c.

The ſharp-pointed ſock is the moſt proper and beſt adapted for all the rough ſtony ſorts of land, being the leaſt in danger of being thrown out of work in them. They are, therefore, the moſt commonly employed. The feather-edged ſock is the moſt uſeful in all ſuch ſoils as are in a great meaſure free from ſtones, though they may be rough on the top. They are, however, occaſionally made uſe of in other circumſtances and caſes. The feathers of them vary conſiderably in their nature and forms; ſome being ſmall and flat, others large and upright, ſo as to ſuit different purpoſes and intentions.

There is alſo a mixed kind of ſock, which has not only a pointed part, but a feathered one likewiſe. This is found very uſeful in ploughing, in many caſes, where the lands are of the leſs ſtony kinds.

All the different kinds of ſocks ſhould be made in ſuch a manner as to fit the ſheath, or fore-part of the head of the plough in the moſt exact manner, as much in the buſineſs of ploughing depends upon this being nicely adjuſted. See Plough.

Sock, *Paring*, that ſort of ſock which is made uſe of on any common plough, for the purpoſe of paring off the ſurface of ſward land. A ſock of this kind may be ſeen at *fig.* 9. *Plate Paring Ploughs*, which has an upright cutting feather, with an outſide cutting wing, and a middle hollow part to be put upon the ſheath or head of any common plough. It is very convenient and uſeful on many occaſions, as it is capable of being employed upon any plough which the farmer may chance to have by him.

SOCKE, the drainage of a farm-yard, or any other yard where dung is laid. See Farm-*Yard*.

Socke-*Pit*, the receiver or receptacle of the farm-yard drainage or liquids.

SOCKET. Ball and ſocket. See Ball.

SOCKETS, in a *Ship*, are the holes which the pintles of the murthering pieces go into.

SOCKIA, in *Geography*, a town of Arabia, in the province of Hedsjas; 75 miles S. of Medina.

SOCKNA, a town of Africa, in Fezzan; 150 miles N.N.W. of Mourzouk.

SOCLE, or Zocle, in *Architecture*, a flat, ſquare member under the baſes of pedeſtals, of ſtatues, vaſes, &c. which it ſerves as a foot, or ſtand.

The word is French, formed from the Italian *zoccolo*, or the Latin *ſoccus*, the ſhoe of the ancient comic actors. Vitruvius calls it *quadra;* we frequently denominate it *plinth*.

Socle, *Continued*, is a kind of continued ſtand, or pedeſtal, without either baſe or corniche, ranging round the whole building; called, by Vitruvius, *ſtereobata;* and, by the French, *ſoubaſſement*.

SOCLO, in *Geography*, a river on the coaſt of the iſland of Mindoro, which runs into the ſea, N. lat. 22° 56′. E. long. 121° 15′.

SOCMEN, or Sokemen, *Socmanni*, ſuch tenants as held their lands and tenements in *ſocage;* but the tenants in ancient demeſne ſeem moſt properly to be called *ſocmans*. See Soc and Villenage.

SOCNA, in our *Old Writers*, a privilege, liberty, or franchiſe. The word is Saxon.

SOCO, in *Ornithology*, the name of a Braſilian bird of the heron-kind, the *ardea Braſilienſis* of Linnæus, remarkable,

able, beyond all the reſt of that genus, for the length of its neck. It is very common in the Braſils; it is ſmaller than the common heron; its beak is ſtrong, ſtraight, and ſharp; its tail ſhort; its head and neck brown, and variegated with black; and its body is of the ſame colours in different variegations, but its wings have a mixture of whiteneſs. See HERON.

SOCOA, in *Geography*, a ſea-port of France, in the department of the Lower Pyrenées; 8 miles S.S.W. of Bayonne. N. lat. 43° 14′. W. long. 1° 36′.

SOCOCA, a town of Peru, in the dioceſe of La Paz; 80 miles E.S.E. of Lipas.

SOCOH, Soco, *Socho*, or *Shoco*, in *Ancient Geography*, a city of Judah (Joſh. xv. 35. 1 Sam. xvii. 1.), repaired by Heber (1 Chron. iv. 18.), and the place in which his family reſided; and afterwards fortified by Rehoboam. (2 Chron. xi. 7.) According to Euſebius, there were two cities named *Socoh*, the higher and the lower; 9 miles from Eleutheropolis towards Jeruſalem.

SOCOME, in our *Law-Books*, &c. a cuſtom of grinding corn at the lord's mill.

There is a *bond-ſocome*, where the tenants are bound to it; and *love-ſocome*, where they do it freely, out of affection to the lord. See MOLTA.

SOCONUSCO, in *Geography*, a province of Mexico, in the audience of Guatimala, bounded on the north by the province of Chiapa, on the eaſt by Vera Paz and Guatimala, on the ſouth by the Pacific ocean, and on the weſt by the Pacific ocean and Guaxaca. The climate is very hot, the rainy ſeaſon from April to September, and ſtorms are very frequent; ſo that the country is far from being either healthy or pleaſant; nor does the ſoil produce much corn, but it affords great quantities of indigo and cocoa-nuts, which are exported by ſea to all the other parts of New Spain. The few Spaniards of this country are very opulent.

SOCONUSCO, or *Guevetlan*, a town of Mexico, capital of a province of the ſame name, ſituated on a river near the North Pacific ocean; 460 miles S.E. of Mexico. N. lat. 15° 28′. W. long. 94° 36′.

SOCORRO, an iſland in the North Pacific ocean, about 20 miles in circumference, uninhabited, and barren; about 200 miles W. from the coaſt of Mexico. N. lat. 18° 30′. W. long. 120° 40′.

SOCOS, a ſmall iſland in the Atlantic, near the coaſt of Africa. S. lat. 19° 45′.

SOCOTAI, a town of Upper Siam; 30 miles S.W. of Porſelouc. N. lat. 17° 30′. E. long. 117°.

SOCOTAN, a town of Perſia, in the province of Arokhage; 120 miles E. of Arokhage.

SOCOTORA, or SOCOTRA, an iſland in the Arabian ſea, about 25 leagues from Cape Guardafu, in length about 24 leagues, and in breadth 16. Its ſhore is bold, and affords ſafe anchorage and good ports: two of its harbours and bays, *viz.* thoſe of Benin and Cora, are particularly diſtinguiſhed, on account of the ſecurity they give to ſhipping againſt every wind that blows. Of this iſland, though much frequented by different trading nations, very various and contradictory accounts have been given by different authors. Some ſay that it has only one town, called "Tamart," or "Tamary;" whilſt others ſay, that this is the chief of three towns; and others again ſtate, that it has neither town, village, nor houſe, and that the inhabitants ſhelter themſelves from the heat of the ſun in ſubterraneous dens and caves. It is agreed, however, that the iſland is populous and fertile, under the government of a prince, or ſultan, who was tributary to the ſheriffs of Arabia. The inhabitants are moſtly Mahometans, who denominate themſelves Arabs, and who reſemble them in their manners and language. The whole iſland abounds in cattle and fruit, with which, beſides ſome other commodities, they trade to Goa, where they are more favourably received than the native Arabs, who are not allowed to enter that town without paſſports. The produce of the iſland conſiſts chiefly in aloes, for which it is proverbially famous, frankincenſe, ambergris, dragon's blood, rice, dates, and coral, which paſs from Goa to many parts of the Indies, and to all the kingdoms of Europe. The Eaſt India ſhips formerly ſtopped here, when diſappointed of their paſſage by the monſoons; but of late the periods of theſe winds have been ſo well aſcertained, that this port is entirely neglected. N. lat. 12° 15′. E. long. 54°.

SOCRATES, in *Biography*, an ancient moral philoſopher, eminently diſtinguiſhed by his principles and conduct, and proverbially recognized as one of the wiſeſt and beſt men, whoſe name and character hiſtory has recorded. He was born at Alopece, a village near Athens, in the fourth year of the 77th Olympiad, B.C. 469. His parentage was obſcure; his father, Sophroniſcus, being a ſtatuary, and his mother, Phænareta, a midwife; and at an early age he was employed in his father's buſineſs, and is ſaid to have executed ſtatues of the habited Graces, which were allowed a place in the citadel of Athens. His patrimony, upon the death of his father, was only the ſmall ſum of 80 minæ, or about 300*l.*; and this ſum he loſt by the diſhoneſty of a relation, with whom his father had entruſted it. Thus reduced to the neceſſity of ſupporting himſelf by manual labour in the exerciſe of his profeſſion, as a ſtatuary, he could only command occaſional intervals, which he devoted to the ſtudy of philoſophy. He ſoon, however, obtained the patronage of Crito, a wealthy Athenian, who engaged him in the office of inſtructing his children; and in this ſituation he availed himſelf of the opportunities, which were thus afforded him, of attending the public lectures of the moſt eminent philoſophers. Ardently devoting himſelf to his favourite purſuits, he choſe, for his firſt preceptor, Anaxagoras; and when he left Athens, he attached himſelf to Archelaus. Prodicus, the ſophiſt, was his preceptor in eloquence, Evenus in poetry, Theodorus in geometry, and Damo in muſic; and he alſo derived conſiderable aſſiſtance in his education from Aſpaſia, a woman highly celebrated for her intellectual as well as perſonal accompliſhments, to whoſe houſe perſons of the moſt diſtinguiſhed character reſorted. So diligent and ſo ſucceſsful was Socrates in the improvement of theſe advantages, that his endowments, both natural and acquired, attracted attention; and he appeared at Athens, equally diſtinguiſhed as a true philoſopher and a good citizen. The military valour of Socrates was no leſs conſpicuous than the other qualities which were more adapted to a retired life; nor did he decline any ſervice, however hazardous or difficult, which private friendſhip or the public intereſt demanded. On one occaſion he preſerved the life and arms of Alcibiades, when he fell wounded in an engagement, in which they were jointly concerned; and in order to encourage the riſing merit of this noble youth, he declined the prize of valour, which was unqueſtionably due to himſelf, and gave his vote that it might be beſtowed on Alcibiades. On another occaſion, he hazarded his own life, in order to reſcue Xenophon, who was left wounded on the field of battle, and carried him on his ſhoulders till he was out of reach of the enemy.

Socrates, declining military expeditions, ſettled at Athens; and he was upwards of 60 years, before he undertook to ſerve his country in any civil office. Accordingly he was choſen to repreſent his own diſtrict in the ſenate of 500; and though he was firſt treated contemptuouſly by his colleagues,

leagues, on account of his inexperience, he ſoon convinced them that in wiſdom and integrity he was much their ſuperior. No conſideration could ever induce him to give a vote, or ſanction a meaſure, that appeared to him to be contrary to juſtice and the laws; and in oppoſition to the thirty tyrants, whoſe proceedings ſeemed to him to be cruel and oppreſſive, he expoſed even his life to danger in ſupporting, with undaunted firmneſs, the rights of his fellow-citizens; and when they iſſued an order to apprehend a wealthy citizen of Salamis, which he diſapproved, he refuſed to execute it, alleging that he would rather ſuffer death himſelf, than be inſtrumental in inflicting it unjuſtly upon another. Theſe proofs of public virtue, both in a military and civil capacity, ſays one of his biographers, are ſufficient to entitle the name of Socrates to a diſtinguiſhed place in the catalogue of good citizens. But his higheſt honour and praiſe are thoſe which belong to him as a philoſopher and moral preceptor. Obſerving with regret how the Athenian youth were miſled, and even corrupted in their principles and taſte, by the mode of teaching that prevailed among ſpeculative philoſophers and artful ſophiſts, he determined to inſtitute a new and more uſeful method of inſtruction. He juſtly conceived the true end of philoſophy to be, not to make an oſtentatious diſplay of ſuperior learning and ability in ſubtle diſputations or ingenious conjectures, but to free mankind from the dominion of pernicious prejudices; to correct their vices; to inſpire them with the love of virtue, and thus conduct them in the path of wiſdom to true felicity. He, therefore, aſſumed the character of a moral philoſopher; and, looking upon the whole city of Athens as his ſchool, and all who were diſpoſed to lend him their attention as his pupils, he ſeized every occaſion of communicating moral wiſdom to his fellow-citizens. He paſſed his time chiefly in public. It was his cuſtom, in the morning, to viſit the places made uſe of for walking and public exerciſes; at noon, to appear among the crowds in the markets or courts; and to ſpend the reſt of the day in thoſe parts of the city which were moſt frequented. Sometimes he collected an audience about him in the Lyceum, (a pleaſant meadow on the border of the river Ilyſſus,) where he delivered a diſcourſe from the chair, whilſt his auditors were ſeated on benches around him. At other times he converſed, in a leſs formal way, with any of his fellow-citizens in places of common reſort, or with his friends at meals, or in their hours of amuſement; thus making every place to which he came a ſchool of virtue. Not only did young men of rank and fortune attend upon his lectures, but he ſought for diſciples even among mechanics and labourers.

The method of inſtruction, which Socrates chiefly made uſe of, was, to propoſe a ſeries of queſtions to the perſon with whom he converſed, in order to lead him to ſome unforeſeen concluſion. He firſt gained the conſent of his reſpondent to ſome obvious truths, and then obliged him to admit others, from their relation, or reſemblance, to thoſe to which they had already aſſented. Without making uſe of any direct argument or perſuaſion, he choſe to lead the perſon he meant to inſtruct, to deduce the truths of which he wiſhed to convince him, as a neceſſary conſequence from his own conceſſions. He commonly conducted theſe conferences with ſuch addreſs, as to conceal his deſign, till the reſpondent had advanced too far to recede. On ſome occaſions, he made uſe of ironical language, that vain men might be caught in their own replies, and be obliged to confeſs their ignorance. He never aſſumed the air of a moroſe and rigid preceptor, but communicated uſeful inſtruction with all the eaſe and pleaſantry of polite converſation.

The modeſty of Socrates was no leſs diſtinguiſhed than his wiſdom. He profeſſed "to know only this, that he knew nothing;" meaning by this declaration, which he often repeated, that he had no other intention than to convince his hearers of the narrow limits of the human underſtanding. Far from encouraging univerſal ſcepticiſm, he always ſpoke confidently and decidedly on moral ſubjects; but at the ſame time he wiſhed to expoſe to contempt the arrogance of thoſe pretenders to ſcience, who would not acknowledge themſelves to be ignorant of any thing. He preferred moral to ſpeculative wiſdom; and therefore condemned thoſe whoſe whole attention and time were occupied about abſtruſe reſearches into nature, and who took no pains to render themſelves uſeful to mankind. His favourite maxim was, "whatever is above us, doth not concern us." He eſtimated the value of knowledge by its utility, and recommended the ſtudy of geometry, aſtronomy, and other ſciences, only ſo far as they admit of a practical application to the purpoſes of human life. His great object, in all his conferences and diſcourſes, was to lead men into an acquaintance with themſelves; to convince them of their follies and vices; to inſpire them with the love of virtue; and to furniſh them with uſeful moral inſtructions. Cicero might, therefore, very juſtly ſay of Socrates, that he was the firſt who called down philoſophy from heaven to earth, and introduced her into the public walks and domeſtic retirements of men, that ſhe might inſtruct them concerning life and manners.

The moral leſſons which Socrates taught, he himſelf diligently practiſed; whence he excelled other philoſophers in perſonal merit, no leſs than in his method of inſtruction. His conduct was uniformly ſuch as became a teacher of moral wiſdom. His mind, through the whole of his life, was ſuperior to the attractions of wealth and power. His inſtructions were gratuitous, and he refuſed rich preſents, that were offered to him by Alcibiades and others, though his wife earneſtly importuned him to accept them. He wanted little for his own perſonal accommodation. In his clothing and food, he conſulted only the demands of nature. Although his fare was ſimple, he was hoſpitable; and ſometimes invited men of ſuperior rank to partake of his meals. On one of theſe occaſions, his wife complained of the incompetency of their proviſion for their gueſts; but to theſe complaints he merely replied, that if his gueſts were wiſe men, they would be ſatiſfied with the proviſions which his table afforded; if otherwiſe, they were unworthy of notice. "Whilſt others," ſays he, "live to eat, wiſe men eat to live." He knew, that temperance was conducive to health, and he found by experience that this was the caſe; for he eſcaped infection in the midſt of the plague which proved ſo fatal to his fellow-citizens.

Although he admired a fair external form, as the index of a mind poſſeſſed, or at leaſt capable, of moral beauty, and converſed freely with young perſons of both ſexes, in order to aſſiſt their progreſs in wiſdom and virtue; yet his enemies have never been able to fix upon him the charge of incontinence. "Modern calumnies," ſays our biographer, "which impute to this great man vices, with which he was never charged by his contemporaries, ought to be treated with univerſal contempt." In his domeſtic connection he was unfortunate, yet he converted this into an occaſion of exerciſing his virtue. Xantippe, of whom many tales, that are mere fabrications, are related, was without doubt a woman of a high and unmanageable ſpirit.

Socrates himſelf, however, allows that ſhe poſſeſſed many domeſtic virtues; and towards the cloſe of his life, and during his impriſonment, ſhe expreſſed great affection for her huſband; and, indeed, after twenty years' experience, it would have been ſtrange, if it had been otherwiſe. On all occaſions, however, at home and abroad, he maintained an unruffled equanimity of temper; always exerciſing that ſelf-command, which is founded on virtuous principles, and ſtrengthened by reflection and habit. In this reſpect he was the more praiſe-worthy, as he himſelf acknowledges, that he was, in his natural diſpoſition, prone to vice, but that he had ſubdued his inclinations by the power of reaſon and philoſophy. This divine power of reaſon was probably the genius, or demon, which, from time to time, gave him inſtruction. Without admitting every thing which his diſciples have ſaid on this ſubject, it is poſſible that Socrates might, in ſome degree, be influenced by ſuperſtitious credulity, concerning this demon; for Xenophon expreſsly atteſts, that he believed that the gods ſometimes communicate to men the knowledge of future events, and that, on this principle, he encouraged the practice of divination.

It was one of the maxims of Socrates, "that a wiſe man will worſhip the gods according to the inſtitutions of the ſtate to which he belongs." He taught, however, a doctrine concerning religion much more pure and rational, than that which was delivered to the people by the prieſts, and he reprobated the popular fables concerning the gods. Convinced of the weakneſs of the human underſtanding, and perceiving that the pride of philoſophy had led his predeceſſors into futile ſpeculations on the nature and origin of things, he judged it moſt conſiſtent with true wiſdom to ſpeak with caution and reverence concerning the divine nature. Nevertheleſs, there can be no doubt that, whilſt he did not deny the exiſtence of inferior divinities, he acknowledged the being and providence of one Supreme Deity, and paid homage, with a pious mind, to the ſovereign power.

In fine, Socrates, both on account of his abilities as a moral preceptor, and on account of his perſonal merit, unqueſtionably deſerves to be ranked in the firſt order of human beings. "The man," ſays Xenophon, "whoſe memoirs I have written, was ſo pious, that he undertook nothing without aſking counſel of the gods; ſo juſt, that he never did the ſmalleſt injury to any one, but rendered eſſential ſervices to many; ſo temperate, that he never preferred pleaſure to virtue; and ſo wiſe, that he was able, even in the moſt difficult caſes, without advice, to judge what was expedient and right. He was eminently qualified to aſſiſt others by his counſel; to penetrate into men's characters; to reprehend them for their vices; and to excite them to the practice of virtue. Having found all theſe excellencies in Socrates, I have ever eſteemed him the moſt virtuous and the happieſt of men."

Socrates, notwithſtanding the ſuperiority of his talents, the excellence of his character, and the number of his followers, who venerated and eſteemed him, had many enemies. They were chiefly intereſted *Sophiſts* (ſee SOPHIST), whoſe influence and whoſe emoluments were diminiſhed in conſequence of the prevalence of his doctrines and precepts. In order to degrade him in the eſtimation of the Athenian youth, and to reſtrain his popularity, they engaged Ariſtophanes, the firſt buffoon of the age, to write a comedy, in which Socrates ſhould be the principal character. Ariſtophanes, pleaſed with ſo promiſing an occaſion of diſplaying his low and malignant wit, undertook the taſk, and produced the comedy of "The Clouds," ſtill extant in his works. In this piece Socrates is introduced hanging in a baſket in the air, and thence pouring forth abſurdity and profaneneſs. The philoſopher, though he ſeldom viſited the theatre, except when the tragedies of Euripides were performed, attended the repreſentation of this play, at a time when the houſe was crowded with ſtrangers, who happened to be at Athens during the celebration of a Bacchanalian feſtival. When the performer, who repreſented Socrates, appeared upon the ſtage, a general whiſper paſſed along the benches on which the ſtrangers ſat, to inquire who the perſon was whom the poet meant to ſatirize. Socrates, who had taken his ſtation in one of the moſt public parts of the theatre, obſerved this circumſtance; and immediately, with great coolneſs, roſe up, to gratify the curioſity of the audience, and continued ſtanding during the remainder of the repreſentation. One of the ſpectators, aſtoniſhed at the magnanimity which this action diſcovered, aſked him, whether he did not feel himſelf much chagrined, to be thus held up to public deriſion. "By no means," replied Socrates, "I am only a hoſt at a public feſtival, where I provide a large company with entertainment."

Theſe efforts of envy and malice, however, were not of long duration. When Ariſtophanes attempted, the year following, to renew the piece with alterations and additions, the repreſentation was ſo much diſcouraged, that he was obliged to diſcontinue it. The conſequence was, that the Sophiſts, and other opponents of Socrates, who appear to have made uſe of the expedient of the theatrical repreſentation, in order to ſound the inclinations of the public, choſe to poſtpone the farther proſecution of their malignant intention to a more favourable opportunity.

From this time, Socrates continued, for many years, to proſecute his laudable deſign of inſtructing and reforming his fellow-citizens. But as he perſevered in oppoſing every kind of political corruption and oppreſſion, both under the democracy and oligarchy, the number of his enemies increaſed, and a conſpiracy, which had been long concerted againſt his life, was reſumed. Clandeſtine arts were uſed, after the diſſolution of the tyranny, to excite a general prejudice againſt him. The people were induſtriouſly reminded, that Critias, who had been one of the moſt cruel of the thirty tyrants, and Alcibiades, who had inſulted religion by defacing the public ſtatues of Mercury, and performing a mock repreſentation of the Eleuſinian myſteries, had, in their youth, been diſciples of Socrates. The minds of the people being thus inflamed, a direct accuſation was preferred againſt Socrates before the ſupreme court of judicature. His accuſers were Anytus, a leather-dreſſer, who had long entertained a perſonal enmity againſt Socrates, for reprehending his avarice, in depriving his ſons of the benefits of learning, that they might purſue the gains of trade; Melitus, a young rhetorician, who was capable of undertaking any thing for the ſake of gain; and Lycon, who was glad of an opportunity of diſplaying his talents. The accuſation, which was delivered to the ſenate under the name of Melitus, was this: "Melitus, ſon of Melitus, of the tribe of Pythos, accuſeth Socrates, ſon of Sophroniſcus, of the tribe of Alopece. Socrates violates the laws, in not acknowledging the gods which the ſtate acknowledges, and by introducing new divinities. He alſo violates the laws by corrupting the youth. Be his puniſhment death."

This charge was delivered upon oath to the ſenate, and Crito, a friend of Socrates, became ſurety for his appearance on the day of trial. Anytus, ſoon afterwards, ſent a private meſſage to Socrates, aſſuring him, that if he would deſiſt from cenſuring his conduct, he would withdraw his accuſation. But Socrates refuſed to comply with ſo degrading a condition, and, with his uſual ſpirit, replied, "Whilſt I live I will never diſguiſe the truth, nor ſpeak otherwiſe than my duty requires." The interval between the accuſation and the trial he ſpent in philoſophical converſations with his friends, chuſing to diſcourſe upon any other ſubject, rather than his own ſituation. Hermogenes, one of his friends, was much ſtruck with this circumſtance, and aſked him, why he did not employ his time in preparing his defence: "Becauſe," replied Socrates, "I have never in my life done any thing unjuſt." The eminent orator Lyſias compoſed an apology, in the name of his maſter, which he requeſted him to adopt; but Socrates excuſed himſelf by ſaying, that though it was eloquently written, it would not ſuit his character.

When the day of trial arrived, his accuſers appeared in the ſenate, and attempted to ſupport their charge in three diſtinct ſpeeches, which ſtrongly marked their reſpective characters. Plato, who was a young man, and a zealous follower of Socrates, then roſe up to addreſs the judges in defence of his maſter: but whilſt he was attempting to apologize for his youth, he was abruptly commanded by the court to ſit down. Socrates, however, needed no advocate. Aſcending the chair with all the ſerenity of conſcious innocence, and with all the dignity of ſuperior merit, he delivered, in a firm and manly tone, an unpremeditated defence of himſelf, which ſilenced his opponents, and ought to have convinced his judges. After tracing the progreſs of the conſpiracy which had been raiſed againſt him to its true ſource, the jealouſy and reſentment of men whoſe ignorance he had expoſed, and whoſe vices he had ridiculed and reproved, he diſtinctly replied to the ſeveral charges brought againſt him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious feſtivals. The crime of introducing new divinities, with which he was charged, chiefly, as it ſeems, on the ground of the admonitions which he profeſſed to have received from an inviſible power, he diſclaimed, by pleading, that it was no new thing for men to conſult the gods, and receive inſtructions from them. To refute the charge of his having been a corrupter of youth, he urged the example which he had uniformly exhibited of juſtice, moderation, and temperance, the moral ſpirit and tendency of his diſcourſes, and the effect which had actually been produced by his doctrine upon the manners of the young. Then, diſdaining to ſolicit the mercy of his judges, he called upon them for that juſtice, which their office and their oath obliged them to adminiſter, and profeſſing his faith and confidence in God, reſigned himſelf to their pleaſure.

The judges, whoſe prejudices would not ſuffer them to pay due attention to this apology, or to examine with impartiality the merits of the cauſe, immediately declared him guilty of the crimes of which he ſtood accuſed. Socrates, in this ſtage of the trial, had a right to enter his plea againſt the puniſhment which the accuſers demanded, and inſtead of the ſentence of death, to propoſe ſome pecuniary amercement. But he, at firſt, peremptorily refuſed to make any propoſal of this kind, imagining that it might be conſtrued into an acknowledgment of guilt; and aſſerted, that his conduct merited, from the ſtate, reward rather than puniſhment. At length, however, he was prevailed upon by his friends to offer, upon their credit, a fine of thirty *minæ*. The judges, notwithſtanding, ſtill remained inexorable: they proceeded, without farther delay, to pronounce ſentence upon him; and he was condemned to be put to death by the poiſon of hemlock. Socrates received the ſentence with perfect compoſure, and by a ſmile teſtified his contempt both for his accuſers and his judges. Then, turning to his friends, he expreſſed his entire ſatisfaction in the recollection of his paſt life, and declared himſelf firmly perſuaded, that poſterity would do ſo much juſtice to his memory as to believe, that he had never injured or corrupted any one, but had ſpent his days in ſerving his fellow-citizens, by communicating to them, without reward, the precepts of wiſdom. Converſing in this manner, he was conducted from the court to the priſon, which he entered with a ſerene countenance and a lofty mind, amidſt the lamentations of his friends.

On the day of the condemnation, it happened that the ſhip, which was employed to carry a cuſtomary annual offering to the iſland of Delos, ſet ſail. It was contrary to the law of Athens, that, during this voyage, any capital puniſhment ſhould be inflicted within the city. This circumſtance delayed the execution of the ſentence againſt Socrates for thirty days. So long an interval of painful expectation, however, only ſerved to afford farther ſcope for the diſplay of his conſtancy. When his friends were with him, he converſed with his uſual cheerfulneſs. In their abſence, he amuſed himſelf with writing verſes. He compoſed a hymn in honour of Apollo and Diana, and verſified a fable of Æſop. His friends, ſtill anxious to ſave ſo valuable a life, urged him to attempt his eſcape, or at leaſt to permit them to convey him away; and Crito went ſo far, as to aſſure him that, by his intereſt with the gaoler, it might be eaſily accompliſhed, and to offer him a retreat in Theſſaly; but Socrates rejected the propoſal, as a criminal violation of the laws; and aſked them, whether there was any place out of Attica which death could not reach.

News being, at length, brought of the return of the ſhip from Delos, the officers, to whoſe care he was committed, delivered to Socrates, early in the morning, the final order for his execution, and immediately, according to the law, ſet him at liberty from his bonds. His friends, who came thus early to the priſon that they might have an opportunity of converſing with their maſter through the day, found his wife ſitting by him with a child in her arms. As ſoon as Xantippe ſaw them, ſhe burſt into tears, and ſaid, "O Socrates, this is the laſt time your friends will ever ſpeak to you, or you to them." Socrates, that the tranquillity of his laſt moments might not be diſturbed by her unavailing lamentations, requeſted that ſhe might be conducted home. With the moſt frantic expreſſions of grief, ſhe left the priſon. An intereſting converſation then paſſed between Socrates and his friends, which chiefly turned upon the immortality of the ſoul. In the courſe of this converſation, Socrates expreſſed his diſapprobation of the practice of ſuicide, and aſſured his friends, that his chief ſupport in his preſent ſituation was an expectation, though not unmixed with doubts, of a happy exiſtence after death. "It would be inexcuſeable in me," ſaid he, "to deſpiſe death, if I were not perſuaded that it will conduct me into the preſence of the gods, who are the moſt righteous governors, and into the ſociety of juſt and good men: but I derive confidence from the hope, that ſomething of man remains after death, and that the condition of good men will then be much better than that of the bad." Crito, afterwards aſking him in what manner he wiſhed to be buried, Socrates replied, with a ſmile, "As you pleaſe, provided I do not eſcape out of your hands." Then, turning to the reſt of his friends, he ſaid, "Is it not ſtrange, after all that I have ſaid to convince you that I am going to the ſociety of the happy, that Crito ſtill thinks this body, which will ſoon be a lifeleſs corpſe, to be Socrates? Let him diſpoſe of my body as he pleaſes, but let him not, at its interment, mourn over it, as if it were Socrates."

Towards the cloſe of the day, Socrates retired into an adjoining apartment to bathe; his friends, in the mean time, expreſſing to one another their grief, at the proſpect of loſing ſo excellent a father, and being left to paſs the reſt of their days in the ſolitary ſtate of orphans. After a ſhort interval, during which he gave ſome neceſſary inſtructions to his domeſtics, and took his laſt leave of his children, the attendant of the priſon informed him, that the time for drinking the poiſon was come. The executioner, though accuſtomed to ſuch ſcenes, ſhed tears, as he preſented the fatal cup. Socrates received it without change of countenance, or the leaſt appearance of perturbation: then, offering up a prayer to the gods, that they would grant him a proſperous paſſage into the inviſible world, with perfect compoſure he ſwallowed the poiſonous draught. His friends around him burſt into tears. Socrates alone remained unmoved. He upbraided their puſillanimity, and entreated them to exerciſe a manly conſtancy, worthy of the friends of virtue. He continued walking, till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining, for a ſhort time, ſilent, he requeſted Crito (probably in order to refute a calumny which might prove injurious to his friends after his deceaſe), not to neglect the offering of a cock, which he had vowed to Eſculapius. Then covering himſelf with his cloak, he expired. Such was the fate of the virtuous Socrates! a ſtory, ſays Cicero, which I never read without tears.

The friends and diſciples of this illuſtrious teacher of wiſdom were deeply afflicted by his death, and attended his funeral with every expreſſion of grief. Apprehenſive, however, for their own ſafety, they, ſoon afterwards, privately withdrew from the city, and took up their reſidence in diſtant places. Several of them viſited the philoſopher Euclid, of Megara, by whom they were kindly received.

No ſooner was the unjuſt condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who univerſally regretted that ſo diſtinguiſhed an advocate for virtue ſhould have fallen a ſacrifice to jealouſy and envy. The Athenians themſelves, ſo remarkable for their caprice, who never knew the value of their great men till after their death, ſoon became ſenſible of the folly, as well as criminality, of putting to death the man who had been the chief ornament of their city, and of the age, and turned their indignation againſt his accuſers. Melitus was condemned to death, and Anytus, to eſcape a ſimilar fate, went into voluntary exile. To give a farther proof of the ſincerity of their regret, the Athenians, for a while, interrupted public buſineſs; decreed a general mourning; recalled the exiled friends of Socrates; and erected a ſtatue to his memory in one of the moſt frequented parts of the city. His death happened in the firſt year of the ninety-ſixth Olympiad, and in the 70th year of his age. Brucker's Hiſt. Phil. by Enfield, vol. i.

Socrates, an eccleſiaſtical hiſtorian, was born and educated at Conſtantinople; and having ſtudied under the grammarians Helladius and Ammonius, he commenced his career at the bar. But after ſome time he relinquiſhed the profeſſion of a law-pleader, and engaged in writing his eccleſiaſtical hiſtory, which comprehends, in ſeven books, the interval of about 133 years, from the year 306, when Conſtantine was declared emperor, to the ſeventeenth conſulſhip of Theodoſius, A.D. 439, in which year Cave repreſents him as flouriſhing. Socrates, Sozomen, and Theodoret, may be conſidered as continuators of Euſebius of Cæſarea; and theſe three writers, who lived in the time of Theodoſius the younger, whoſe reign extended from the year 408 to 450, publiſhed their reſpective hiſtories, which are valuable monuments of antiquity, about the ſame time, near the end of this reign. Socrates ſeems to have been diſtinguiſhed by his moderation and candour, which we may infer from the freedom with which he cenſures the ſquabbles and contentions that ſubſiſted amongſt the Chriſtian clergy in thoſe times, and condemns the perſecution that occurred in the reign of Julian. From the candid manner in which he expreſſes his ſentiments concerning the Novatians, ſome perſons have erroneouſly concluded that he was one of their number.

As an hiſtorian, Socrates has the merit of being judicious in his obſervations upon men and things, and generally accurate in his chronology. He ſpeaks with great reſpect of the ſcriptures of the Old and New Teſtaments; and has expreſsly quoted the Acts of the Apoſtles, and the Epiſtles to the Romans, the Corinthians, the Galatians, the Coloſſians, and the Hebrews: he likewiſe takes notice of a various reading in 1 John, iv. 3. The work of Socrates was tranſlated into Latin by thoſe who made verſions of the other Greek eccleſiaſtical hiſtorians, and is uſually printed with them. The beſt editions are thoſe of Valeſius, fol. Paris, 1668, and of Reading, fol. Cant. 1720. Dupin. Lardner.

SOCRATIC Induction, in *Rhetoric*. See Induction.

Socratic *Philoſophy*, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates.

As Socrates left nothing in writing, we are indebted to his illuſtrious pupils, Xenophon and Plato, for what is known both of his opinions and manner of teaching; and more eſpecially to the former, whoſe memoirs of Socrates contain more accurate information than the dialogues of Plato, becauſe he intermixes his own conceptions and diction with the ideas and language of his maſter. Accordingly it is related, that when Socrates heard Plato recite his Lyſis, he ſaid, "How much does this young man make me ſay, which I never conceived!" The diſtinguiſhing character of Socrates was that of a moral philoſopher; and to this purpoſe Xenophon denies that he ever taught natural philoſophy, or any mathematical ſcience, and charges with miſrepreſentation and falſehood thoſe who had aſcribed to him diſſertations of this kind, probably in this charge referring to Plato, in whoſe works Socrates is introduced as diſcourſing on theſe ſubjects.

The doctrine of Socrates concerning God and religion is rather practical than ſpeculative. But he did not neglect to build the ſtructure of religious faith upon the firm foundation of an appeal to natural appearances. He taught, that the Supreme Being, though inviſible, is clearly ſeen in his works, which at once demonſtrate his exiſtence, and his wiſe and benevolent providence. This point is eſtabliſhed, with great perſpicuity and force of reaſoning, in his conferences with Ariſtodemus, and with Euthydemus. "Reflect," ſays he, "that your own mind directs your body by its volitions, and you muſt be convinced that the intelligencer of the univerſe diſpoſes all things according to his pleaſure.—Can you imagine, that your eye is capable of diſcerning diſtant objects, and that the eye of God cannot, at the ſame inſtant, ſee all things; or that, whilſt your mind contemplates the affairs of different countries, the underſtanding of God cannot attend, at once, to all the affairs of the univerſe? Such is the nature of the Divinity, that he ſees all things, hears all things, is every where preſent, and conſtantly ſuperintends all events." Again: "He who diſpoſes and directs the univerſe, who is the ſource of all that is fair and good, who, amidſt ſucceſſive changes, preſerves the courſe of nature unimpaired, and to whoſe laws all beings are ſubject, this Supreme Deity, though himſelf inviſible, is manifeſtly ſeen in his magnificent operations. Learn, then, from the things which are produced, to infer the exiſtence of an inviſible power, and to reverence the Divinity."

Beſides the one Supreme Deity, Socrates admitted the exiſtence of beings who poſſeſs a middle ſtation between God and man, to whoſe immediate agency he aſcribed the ordinary phenomena of nature, and whom he ſuppoſed to be particularly concerned in the management of human affairs. Hence, ſpeaking of the gods, who take care of men, he ſays, "Let it ſuffice you, whilſt you obſerve their works, to revere and honour the gods: and be perſuaded, that this is the way in which they make themſelves known; for, among all the gods, who beſtow bleſſings upon men, there are none who, in the diſtribution of their favours, make themſelves viſible to mortals." Hence, he ſpoke of thunder, wind, and other agents in nature, as ſervants of God, and encouraged the practice of divination, under the notion, that the gods ſometimes diſcover future events to good men.

Concerning the human ſoul, the opinion of Socrates, according to Xenophon, was, that it is allied to the divine being, not by a participation of eſſence, but by a ſimilarity of nature; that man excels all other animals in the faculty of reaſon; and that the exiſtence of good men will be continued after death, in a ſtate in which they will receive the reward of their virtue. Although it appears that, on this latter topic, Socrates was not wholly free from uncertainty, the conſolation which he profeſſed to derive from this ſource in the immediate proſpect of death, leaves little room to doubt, that he entertained a real belief and expectation of immortality. The doctrine which Cicero aſcribes to Socrates, on this head, is, that the human ſoul is a divine principle, which, when it paſſes out of the body, returns to heaven; and that this paſſage is moſt eaſy to thoſe who have, in this life, made the greateſt progreſs in virtue.

The ſyſtem of morality which Socrates made it the buſineſs of his life to teach, was raiſed upon the firm baſis of religion. The firſt principles of virtuous conduct, which are common to all mankind, are, according to this excellent moraliſt, laws of God: and the concluſive argument by which he ſupports this opinion is, that no man departs from theſe principles with impunity. "It is frequently poſſible," ſays he, "for men to ſcreen themſelves from the penalty of human laws, but no man can be unjuſt, or ungrateful, without ſuffering for his crime: hence, I conclude, that theſe laws muſt have proceeded from a more excellent legiſlator than man." Socrates taught, that true felicity is not to be derived from external poſſeſſions, but from wiſdom, which conſiſts in the knowledge and practice of virtue; that the cultivation of virtuous manners is neceſſarily attended with pleaſure, as well as profit; that the honeſt man alone is happy; and that it is abſurd to attempt to ſeparate things, which are in nature ſo cloſely united as virtue and intereſt.

But it is impoſſible, ſays the author whom we are citing, in detached ſentences, to give the reader any tolerable idea of the moral doctrines of Socrates. We muſt therefore refer him, on this head, to that valuable treaſure of ancient wiſdom, the "Memorabilia" of Socrates; a work in which he will find his original converſations on many intereſting topics, related with that beautiful ſimplicity, which diſtinguiſhes the writings of Xenophon.

The followers of Socrates may be divided into three claſſes. The firſt claſs conſiſts of ſuch as were neither philoſophers by profeſſion, nor addicted to the ſtudy of philoſophy, but attended upon Socrates as a moral preceptor, for the purpoſe of correcting and improving their manners. Among theſe were ſeveral young men of the firſt rank in Athens, particularly Alcibiades and Critias. In this claſs may alſo be placed the poets Euenes and Euripides, and the orators Lyſias and Iſocrates. The ſecond claſs included all thoſe who, after his death, became founders of particular ſects, and, though they differed from each other greatly, were united under the general appellation of Socratic philoſophers. Theſe were Ariſtippus, the founder of the Cyrenaic ſect; Phædo, of the Eliac; Euclid, of the Megaric; Plato, of the Academic; and Antiſthenes, of the Cynic. The third claſs comprehends thoſe diſciples of Socrates, who, though their names are found in the catalogue of philoſophers, did not inſtitute any new ſect. The moſt diſtinguiſhed diſciples of the Socratic ſchool are Xenophon, Æſchines, Simon, and Cebes; for an account of whom, ſee their reſpective articles. Brucker's Hiſt. of Phil. by Enfield, vol. i.

SOCRATIS INSULA, in *Ancient Geography*, an iſland of the Arabic gulf, on the coaſt of Arabia Felix. Ptolemy.

SOCUNDA, a town of Hyrcania, according to Ammianus Marcellinus, named Socanaa by Ptolemy, who places it on the coaſt of the Caſpian ſea, between the mouths of the rivers Maxera and Oxus.

SOD, in *Agriculture*, a portion of turf or ſward, cut or dug up. It alſo ſignifies the ſoil or earth. The ſquare pieces of ſurface-turf and earth that are cut up in forming embankments and earth-fences are likewiſe termed ſods, and require nice cutting, ſo as to be exactly joined in performing the works. Sods are uſeful too in ſome other operations of the rural kind.

SOD-*Burning*, the practice of paring off the ſward or moſſy ſurface of the land. It is obſerved by Mr. Marſhall, in the Rural Economy of Weſt Devonſhire, that the moſt noticeable particular of management in the ſoil proceſs of that diſtrict, is that of "burning beat," as it is provincially termed; anſwering to the paring and burning, or more technically, ſod-burning, of other diſtricts; and that this operation in agriculture has been practiſed, in this weſtern part of the iſland, from time beyond which memory or tradition reaches. It has, he conceives, probably been imported from the oppoſite ſhore of the continent. And in an old tract, which he ſaw ſome years ago in the Britiſh Muſeum, this operation is termed *Devonſhiring*, and it is to this day called *Denſhiring*, in different diſtricts of the kingdom. He alſo further ſtates, that there are at preſent three diſtinct methods of ſeparating the ſward or ſod, provincially the "ſpine," from the ſoil. The one is performed with a "beating-axe," namely, a large adze, ſome five or ſix inches wide, and ten or twelve inches long, crooked, and ſomewhat hollow, or *diſhing*. With this, which was probably the original inſtrument employed in the operation, large chips, ſhavings, or ſods, are ſtruck off. It is ſtill uſed in rough uneven grounds, eſpecially where furze, or the ſtubs of bruſhwood abound. In uſing it, the workman appears to the eye of a ſtranger, at ſome diſtance, to be *beating* the ſurface as with a beetle, rather than to be chipping off the ſward with an edged tool. This operation is provincially termed "hand-beating." The next inſtrument in uſe is, he ſays, the ſpade, reſembling the paring ſpade, or breaſt-plough of other diſtricts; with, however, in ſome inſtances at leaſt, a notable addition, namely, a mould-board, fixed in ſuch a manner as to turn the ſod or turf as a plough turns the furrow-ſlice, thus becoming literally a breaſt-plough; a name which has probably been given to the implement in this ſtate, and continued to be applied to the ſpade or ſhare after the mouldboard was laid aſide.

It is added, that in working this tool, the labourer proceeds without ſtopping to divide the ſods into ſhort lengths; this part being done by women and children, who follow to break the turfs into lengths, and ſet the pieces on edge to dry. The price for "ſpading" is about three halfpence a ſquare perch, of eighteen feet, or 16*s.* or 17*s.* a ſtatute acre. Formerly, it is probable, this inſtrument was much uſed, but at preſent it appears to be chiefly in the hands of ſmall farmers.

It is ſtated, that the inſtrument at preſent uſed for ſeparating the ſpine or graſſy turf from the ſoil, by farmers in general, is the common team-plough, with ſome little alteration in the ſize and form of the ſhare, according to the fancy or judgment of the farmer or his ploughman, there being two different ways of performing the operation. The one is termed "velling," the other "ſkirting," or "ſkirwinking." In that for *velling*, the ſhare is made wide, with the angle or outer point of the wing or fin turned upward to ſeparate the turf entirely from the ſoil. But in that for *ſkirting*, the common one is uſed, but made perhaps ſomewhat wider than when it is uſed in the ordinary operation of ploughing. And that in this mode of uſing the plough, little more than half the ſward is pared off, turning the part raiſed upon a line of unmoved turf; as in the operation of ribbing, rice-balking, raftering, or half-ploughing. The paring of turf in this caſe is from one to two inches thick on the coulter margin, decreaſing in thickneſs to a thin feather edge, by which it adheres to the unmoved ſward. And after having lain ſome time in this ſtate to rot, or grow tender, it is pulled to pieces with rough harrows drawn acroſs the lines of turf; and having lain in this rough ſtate until it be ſufficiently dry, it is bruiſed with a roller, and immediately harrowed with light harrows, walking the horſes one way, and trotting them another, to ſhake the earth out more effectually from among the roots of the graſs; going over the ground again, and perhaps again, according to the ſeaſon, and the judgment of the manager, until moſt of the earth be diſengaged. The "beat" of fragments of turfs being ſufficiently dry, is gathered into heaps of five or ſix buſhels each; either with the "drudge," firſt into rows, and then drawing it along the rows into heaps; or is pulled together with long-toothed hand-rakes, adapted to the purpoſe. The former is more expeditious, and requires fewer hands; the latter gathers the beat cleaner, freer from earth, which is liable to be drawn together by the drudge. The "beat burrows" or heaps being rounded, and ſhook up light and hollow, a wiſp of rough ſtraw, a large handful, is thruſt, double, into the windward ſide of each heap; and a number of heaps being thus primed, a match or flambeau is formed, with "reed" or ſtraight unthraſhed ſtraw, one end of which being lighted, it is applied in ſucceſſion to the looſe ragged ends of the wiſp of ſtraw, which readily communicate the fire to the heaps. The centre of the heap being conſumed, the outſkirts are thrown lightly into the dimples or hollows, and the heaps rounded up, as at firſt, continuing to right up the burrows, until the whole of the beat be conſumed, or *changed*, by the action of the fire. And the produce of the firſt ſkirting being burnt and ſpread over the ſurface, the operation is ſometimes repeated by running the plough acroſs the lines of the firſt ſkirting; thus paring off the principal part of the ſpine; again dragging, rolling, harrowing, collecting, and burning, as in the former operation. This is a proceſs of very great importance in the ſyſtem of Devonſhire huſbandry, and by which vaſt advantages and improvements have been effected.

The practice is not now, however, had ſo much recourſe to as formerly, probably on account of its having been carried to too great a length in ſome caſes, and improper modes of cropping having been purſued after it in others; but where well underſtood, it is ſtill an excellent method of preparation in many inſtances and ſituations of land. The great advantages of it ſeem to conſiſt in the reduction and diminution, which it ſo readily affords to the more ſtiff, adheſive, tenacious, clayey ſorts of ſoils; and the quick, certain, and effectual manner in which it brings the inert and uſeleſs vegetable matters of them, into more proper ſtates for the purpoſe of ſupporting plants, in the way of manures, as crops.

It is moſt likely that this practice will be the moſt beneficial in all ſuch ſoils as contain an over-proportion of dead fibrous vegetable matter, or which loſe from about one-third to one-half of their weight by burning; and in all ſuch as contain their earthy conſtituent parts in a finely reduced ſtate of diviſion, ſuch, for inſtance, as ſtrong clays, marles, and ſome other ſimilar kinds: but that in light, coarſe, ſandy, and rich ſoils of other qualities, which contain proper proportions of earthy matters in their compoſition; and in every caſe where the ſtructure and qualities of them are in their preſent ſtates properly looſe, and the organizable matters in them properly and to a ſufficient extent ſoluble, this practice cannot be employed with ſucceſs, though it is ſometimes attempted upon them. The ſiliceous poor ſandy ſoils muſt always, it is ſuppoſed, be greatly hurt by it, as is evident from the practical reſults upon ſuch lands.

It is not improbable, but that in numerous caſes it may have failed, in conſequence of over-burning the turf, or ſome other miſmanagement in the practice, as there may, by ſuch means, be too great a diſſipation and waſte of ſome certain ſubſtances and matters, which are in their nature and properties not only neceſſary, but highly conducive to the fertility and improvement of the ſoil or land. That carbon, or the refuſe of burnt vegetable matters, is of this nature, there can now be no doubt, as the decompoſition of ſuch ſubſtances has fully ſhewn it. This material may, therefore, be too much carried off and deſtroyed in burning the turf of lands, either by combining too freely with the oxygen of the ſurrounding atmoſphere, in conſequence of too great a heat being kept up in the operation, and be thereby loſt in the form of carbonic acid gas; or by combining in too free a manner with certain proportions of hydrogen, ſupplied by the vegetable matter in conſequence of the increaſed heat, and by this means furniſhing a ſort of oleaginous fluid, which is diſſipated in large quantities with great rapidity, when a conſiderable extent of ſurface is expoſed to the air of the atmoſphere, during the time of burning the turf. It is therefore evident, on theſe as well as other accounts, that a ſlow dull ſmothering fire, and as ſmall an expoſure to the open air as poſſible, are both circumſtances particularly neceſſary to the proper effect and ſucceſs of this practice in many caſes, if not in all; as when theſe and ſuch like circumſtances are not well attended to and properly regulated, the aſhes and other matters which are produced, will be, in a great meaſure, deprived and deſtitute of thoſe fertilizing and enriching qualities and properties, which are ſo neceſſary and eſſential to ſubſtances of this kind. See Paring and Burning.

Sod-*Drain*, that ſort of drain which is formed and conſtructed either wholly, or in the greateſt part, of the ſods dug up from the land about them. Theſe ſorts of drains were formerly much in uſe, and thought highly of in ſome diſtricts and places, moſt likely on account of their cheapneſs; but they are now fallen into neglect and diſrepute, probably in conſequence of their want of ſecurity and durability, eſpecially in lands which are under the plough. They are, however, ſtill made uſe of occaſionally on paſture and ſward lands in ſome ſituations. The methods of making them differ in different caſes and circumſtances, according to the nature and kinds of land, being in ſome inſtances formed with much more ſolidity than in others, as may be ſeen under the articles SURFACE-*Drains* and DRAINING. They can perhaps, on the whole, be ſeldom had recourſe to with propriety, except in caſes where other kinds of more ſolid materials are procured with great difficulty.

SOD-*Fence*, any ſort of fence which is conſtructed of materials of this nature, either for incloſing land or defending it againſt the waters of rivers or the ſea. See FENCES.

Theſe kinds of fences, when made againſt the ſea or large rivers, ſhould have a good degree of ſlope, as two, three, or four feet, to one in height, according as the caſe may be. They have in ſome diſtricts, as in Lancaſhire, in many inſtances, a baſe of about forty feet, and ſlope upwards in the direction of the ſea as well as that of the land. The extent of baſe is, however, different in different places, as well as that of the ſlope or ſlopes. Fences of this nature againſt the ſea in the above county, coſt about 3*l.* the rod of eight yards in their conſtruction.

SOD-*Kiln*, any ſort of kiln which is built or conſtructed with ſods, for the purpoſe of burning lime or any other material of that kind. They are very common in ſome places. See KILN.

A very cloſe ſort of ſmothering heat is produced in this way, which readily converts any calcareous matters into lime of a good quality for uſe on land.

SOD-*Knife, Draining*, an implement of the knife kind, which is made uſe of with great advantage in ſcoring and cutting out the ſward or graſſy ſurface in forming drains. It is a very uſeful tool, performing the work in a neat manner.

SODA. See SODIUM.

SODA, in the *Materia Medica. Muriate of Soda.* See MURIATE *of Soda*, SALT, and SALTS. It is obſerved, (ſee Thomſon's Chemiſtry, cited by Mr. A. T. Thomſon in the London Diſpenſatory,) that the common ſalt of commerce contains ſmall portions of muriate of magneſia, muriate of lime, and ſulphate of lime; and for the ſeparation of theſe, the ſalt is to be diſſolved in four times its weight of pure water, and into the filtered ſolution muſt be dropped firſt muriate of barytes, and then ſubcarbonate of ſoda, as long as any precipitate falls. Then filter and evaporate the clear fluid ſlowly till the ſalt cryſtallizes, which is pure muriate of ſoda. This pure muriate of ſoda is inodorous; its taſte is ſtrictly ſalt; and, when pure, perfectly devoid of any degree of bitterneſs. It is in regular cubes, which are not affected by expoſure to the atmoſphere. When it deliqueſces, it contains muriate of magneſia. Its cryſtals decrepitate when heated; and in a red heat melt, loſing about two *per cent.* of their weight; and in a ſtill greater heat the ſalt is volatilized, undecompoſed, in white fumes. Its ſpecific gravity is 2.126. It is equally ſoluble in cold and in hot water, nearly three parts of either being required to diſſolve one of ſalt. It conſiſts, according to Kirwan, of 38.88 of acid, 53.00 ſoda, and 8.12 water in 100 parts. It is decompoſed by ſulphuric acid and nitric acid.

As an article of the Materia Medica, this ſalt is tonic and anthelmintic in moderate doſes; purgative in larger; and externally ſtimulant. In the ordinary mode of uſing it, the tonic power of ſalt operates in aſſiſting the proceſs of digeſtion; and, conſequently, taken more freely, it proves uſeful in dyſpepſia, and in correcting the weakened ſtate of the inteſtines, which favours the propagation of worms. In large doſes it is ſaid to check vomiting of blood, and may be uſed as a purgative; although it is ſeldom employed. But the purgative quality of ſea-water does not altogether depend on this ſalt, as it contains a much larger proportion of muriate of magneſia, which is alſo purgative. As a local ſtimulant, its ſolution in tepid water, in the proportion of ℥ſs or ℥j to oj of water, forms the common domeſtic enema. It is uſed alſo as a fomentation to ſprains and bruiſes; and diſſolved in a large proportion of water, forms the beſt ſtimulant general bath, whether uſed cold, or in a tepid, or a hot ſtate.

With a view to the firſt intentions, the doſe of muriate of ſoda may be from grs. x to ʒj; but to operate by ſtool from ℥ſs to ℥j is neceſſary, largely diluted.

The officinal preparations of this ſalt are as follow; *viz.* "dried muriate of ſoda," which is prepared, according to the Dub. Ph., by taking any quantity of muriate of ſoda, and roaſting it over the fire in an iron veſſel, ſlightly covered, until it ceaſe to decrepitate, occaſionally agitating. According to Kirwan, 100 parts of cryſtallized muriate of ſoda contain 8.12 of water, which are nearly diſſipated by the heat, and the ſalt is thus rendered of a more uniform ſtrength. It is chiefly employed for the diſtillation of MURIATIC *Acid*, (ſee that article,) which is obtained colourleſs from the dried ſalt.

Muriatic acid of the Lond. Ph. is prepared by firſt mixing $1\frac{1}{2}$lb. of ſulphuric acid with half a pint of diſtilled water in a glaſs retort, and when the mixture is cold, adding to it 2lbs. of muriate of ſoda dried: then pouring a pint of the water into the receiver, and having fitted to it the retort placed in a ſand-bath, diſtil over the muriatic acid into this water, with a heat gradually raiſed, until the retort becomes red-hot. The ſpecific gravity of muriatic acid is to that of diſtilled water as 1.170 to 1.000. If a piece of limeſtone be immerſed in a fluid-ounce of it, diluted with water, the quantity diſſolved ought to be half an ounce. The Edinb. Ph. directs the *muriatic acid* to be prepared by firſt expoſing 2lbs. of muriate of ſoda in a pot to a red heat for a ſhort time, and when it is cold, putting it into a retort; then pouring 16 oz. of ſulphuric acid, mixed with 1lb. of water, and cooled, upon the muriate of ſoda; and finally diſtilling from a ſand-bath with a moderate fire, as long as any acid comes over. The ſpecific gravity of this acid is to that of diſtilled water as 1.170 to 1.000. According to the Dubl. Ph. 6lbs. of ſulphuric acid are diluted with the ſame quantity of water; and after it is cold, it is added gradually to 6lbs. of muriate of ſoda, dried and put into a glaſs retort; and then the liquor is diſtilled until the reſiduum becomes dry. The ſpecific gravity of this acid is to that of diſtilled water as 1.170 to 1.000.

This acid, for a farther account of which ſee MURIATIC *Acid*, is tonic and antiſeptic. It has been uſed with effect in typhus fevers, and in ſome cutaneous eruptions. It is a common and uſeful addition to gargles, in the proportion of from fʒſs to fʒij in f℥vj of any fluid, in ulcerated ſore-throats and cancrum oris; and in a very highly diluted ſtate, ♏viij in f℥iv of water, it has been recommended as an injection in gonorrhœa. It has alſo been regarded as an antidote in general ſyphilitic affections; but this opinion has been ſhewn by Mr. Pearſon to be erroneous: nevertheleſs, by its ſalutary effect on the ſtomach and general health, it is capable of ameliorating the appearance of venereal ulcers, and of reſtraining for a time the progreſs of the diſeaſe, when it is deſirable to gain time previouſly to the commencement of a mercurial courſe. The doſe is from ♏x to ♏xx, in a ſufficient quantity of water. Morveau, in 1773, diſcovered the important power of muriatic acid, in the ſtate of gas, for neutralizing putrid miaſmata ; and thus it is uſed as an agent for deſtroying infection in ſick rooms and hoſpitals, diſengaged by pouring ſulphuric acid on common ſalt.

The officinal preparations of muriatic acid are as follow ; "muriate of barytes" (ſee Salts) : the "ſolution of muriate of lime" (ſee Lime and Muriate *of Lime*), which, according to the Edinb. Ph., is prepared by mixing 16 oz. of muriatic acid with 8 oz. of water, and gradually adding 9 oz. of the harder variety of carbonate of lime (*viz.* white marble) broken into ſmall pieces : when the effervefcence is finiſhed, digeſt for an hour ; then pour off the fluid, and reduce it by evaporation to dryneſs : diſſolve the reſiduum in its weight and a half of water, and filter the ſolution. This "water of muriate of lime" is prepared, according to the Dubl. Ph., by adding gradually 2 oz. of diluted muriatic acid to 1 oz. of chalk reduced to a coarſe powder, and when the effervefcence is finiſhed, filtering the ſolution. This ſolution is colourleſs, and has a diſagreeable, bitter, acrid taſte ; it is decompoſed by the ſulphuric, nitric, phoſphoric, fluoric, and boracic acids ; the neutral ſalts into which theſe enter ; and the alkalies and alkaline carbonates which precipitate the lime. In the ſolid ſtate, 100 parts of muriate of lime, after being expoſed to a red heat, conſiſt of 42 of acid, 50 of lime, and 8 of water. By mixing four parts of it with an equal quantity of ſnow, a degree of cold is produced capable of ſinking the mercury in the thermometer from 32° to 40° below 0° of Fahrenheit. Muriate of lime is deobſtruent and tonic. Fourcroy introduced it into practice, and it has been much recommended as a remedy in ſcrophulous and glandular diſeaſes. Mr. T. Thomſon ſays, that he has given it with evident advantage in bronchocele, and that he has witneſſed greater benefit reſulting from the continued uſe of it in the varied forms of ſcrophula, than from any other remedy with which he is acquainted. Its operation is ſimilar to that of muriate of barytes : but the danger of an over-doſe is leſs to be dreaded, and its good effects are more uniform and certain. The doſe of the ſolution is from ♏xx to fʒj, in a ſufficient quantity of water, repeated twice or thrice a day.

Another preparation of muriate of ſoda is "muriate of antimony." (See Antimony.) For an account of the "precipitated ſubmuriate of mercury," and of the "ammoniated ſubmuriate of mercury," ſee Mercury.

The *ſub-borate of ſoda*, (for the chemical properties of which ſee Borax,) purified by ſolution and cryſtallization, is inodorous, and has a ſtyptic, cool, and alkaleſcent taſte ; and as an article of the materia medica, it is refrigerant and detergent. It is not given internally : and its chief application is in aphthous affections of the mouth, and exceſſive ſalivation. It is uſed either in the form of powder mixed with ſugar, or diſſolved in water, and united with honey as a lotion. See Honey.

The *carbonate of ſoda* is prepared, according to the Lond. Ph., by adding 3 oz. of ſubcarbonate of ammonia to a ſolution of 1lb. of ſubcarbonate of ſoda, in a pint of diſtilled water ; then expoſing the mixture in a ſand-bath to a heat of 180° for three hours, or until the ammonia be expelled, and finally ſetting it apart to cryſtallize. The reſiduary liquor may be evaporated in the ſame manner, and ſet apart again to cryſtallize. This ſalt does not appear to poſſeſs any advantages ſuperior to thoſe of the ſubcarbonate as a remedy, and may therefore be regarded as a redundant preparation.

The *ſubcarbonate of ſoda* of the Lond. Ph. is prepared by boiling 1lb. of impure ſoda (barilla) powdered, in a gallon of boiling diſtilled water for half an hour, and filtering the ſolution ; then evaporating it to two pints, and ſetting it apart for cryſtallization : the liquor that remains is thrown away. The *carbonate of ſoda* of the Edinb. Ph., formerly "purified fixed foſſile alkali," is prepared by bruiſing any quantity of impure carbonate of ſoda (ſee Carbonate *of Soda*), and then boiling it in water until all the ſaline matter be diſſolved ; then filtering the ſolution through paper, and evaporating it in an iron veſſel, ſo that after refrigeration cryſtals may be formed. The Dubl. Ph. directs 10lbs. of powdered barilla to be boiled in two gallons of water, in a covered veſſel, for two hours, with occaſional ſtirring ; filtering the liquor ; then bruiſing the barilla that remains with an equal quantity of water, and again boiling it, which may be repeated a third time. The leys being filtered and mixed, evaporate them to dryneſs in a wide iron veſſel, taking care that the ſaline maſs which will remain be not again liquefied by too great a heat ; ſtir it with an iron ſpatula till it becomes white ; finally diſſolve it in boiling water, and, after due evaporation, ſet it apart, that as it cools, cryſtals may form. Theſe will be purer if the barilla before each boiling be expoſed for ſome time to the air. The cryſtallization ſhould be effected when the air is at the freezing temperature, and in a liquor the ſpecific gravity of which is, to that of water, as 1220 to 1000. If the ſalt be not very pure, repeat the ſolution and cryſtallization.

Barilla, beſides the ſubcarbonate of ſoda, contains ſulphate and muriate of ſoda, charcoal, lime, magneſia, argil, and ſilex, from which theſe proceſſes are intended to ſeparate it. One pound of barilla yields from ℥iij to ℥v of the cryſtallized ſubcarbonate.

A very pure ſubcarbonate of ſoda is now manufactured, on a great ſcale, by the decompoſition of ſulphate of ſoda and of muriate of ſoda, which will probably ſuperſede altogether the proceſſes ordered in the pharmacopeias.

Subcarbonate of ſoda has a mild alkaleſcent taſte, and changes the vegetable blue and red colours to green. Its cryſtals are large tranſparent octohedrons, truncated at the ſummits of the pyramids, which effloreſce when expoſed to a dry air, and crumble down into a white opaque powder. It undergoes the watery fuſion ; is ſoluble in two parts of water at 60°, and in conſiderably leſs than its weight of boiling water, its abundant water of cryſtallization aſſiſting the ſolution of the ſalt at that temperature. Its conſtituents, according to the late analyſis of D'Arcet, are, in 100 parts, 16.04 of acid, 20.85 of alkali, and 63.61 of water : which correſponds with the ſtatement of Bergman.

This ſalt is antacid and deobſtruent. It is leſs acrid than the ſubcarbonate of potaſs ; and hence is in more general uſe in dyſpepſia and acidities of the ſtomach, and in ſcrophulous affections. Its uſe has been lately ſtrenuouſly recommended in hooping-cough, the protraction of which it is ſaid to prevent. It is given, at firſt, after the ſtomach and bowels have been duly evacuated, in combination with ipecacuanha and opium, and afterwards, when the violence of the cough has abated, with myrrh. The doſe of this ſalt is from grs. x to ʒſs, given twice or thrice a day, in conjunction with bitters or rhubarb.

The officinal preparations are, "dried ſubcarbonate of ſoda" of the Lond. and "dried carbonate of ſoda" of the Dub. Ph.; "carbonate of ſoda" of the Lond. Ph. ; "water of the ſupercarbonate of ſoda" of the Ed. Ph.; "phoſphate of ſoda" of the Ed. and Dub. Ph.; "ſoda tartarizata" of the Lond. Ed. and Dub. Ph.; "carbonate of iron" of the Lond. Ed. and Dub. Ph.; "carbonate of ammonia," and "water of carbonate of ammonia," of the Dub. Ph.; "precipitated chalk" of the Dub. Ph.; and "benzoic acid" of the Ed. Ph.

The "dried ſubcarbonate of ſoda" of the Lond. Ph. is prepared by expoſing 1lb. of ſubcarbonate of ſoda to a moderate heat in a clean iron veſſel, until it becomes perfectly dry, and at the ſame time ſtirring it diligently with an iron ſpatula, and finally rubbing it into a powder. The Dubl. Ph. directs the "dried carbonate of ſoda" to be prepared by liquefying the cryſtals of carbonate of ſoda in a ſilver crucible over the fire; then, in an augmented heat, ſtirring the diſſolved ſalt, until by the evaporation of the water it becomes dry; reducing it to a fine powder, and preſerving it in ſtopped phials. The conſtituents of 100 parts, in this ſtate, according to the analyſis of Kirwan, are 40.14 of acid, and 59.86 of ſoda. Dr. Beddoes has extolled this ſalt in form of pills, as a remedy in calculous affections; and, as Thomſon ſays, it certainly affords decided relief from the painful ſymptoms attending calculus in the kidnies, and other urinary affections. Its effects, however, are only palliative, and depend on its deſtroying the prevalent acid in the ſtomach; and hence it cannot, in ſtrict language, be regarded as a lithontriptic. The doſe is from grs. x to grs. xv, given three times a day. Beddoes directed it to be combined with ſoap and aromatics.

The "water of ſupercarbonate of ſoda" of the Ed. Ph. is to be prepared from 10lbs. of water, and 2 oz. of ſubcarbonate of ſoda, in the ſame manner as the water of ſupercarbonate of potaſs. This preparation is milder and pleaſanter than the water prepared with ſubcarbonate of potaſs. It is manufactured in large quantities, on a great ſcale, of a much ſuperior quality to any which the apothecary can prepare: and is in very general uſe as a cooling beverage. Half a pint of it poured over two table-ſpoonfuls of lemon-juice, ſweetened with a little ſugar, forms an excellent and very agreeable efferveſcing draught.

The "phoſphate of ſoda" is prepared, according to the Ed. Ph., by mixing 10 lbs. of powdered bones, reduced to whiteneſs, with 6 lbs. of ſulphuric acid, in an earthen veſſel; then adding 9 lbs. of water, and again mixing; keeping the veſſel in a vapour-bath for three days; afterwards diluting the matter with 9 lbs. more of boiling water, and ſtraining through a ſtrong linen cloth, pouring boiling water gradually over it, until the whole of the acid be waſhed out. Set the ſtrained liquor apart, that the impurities may ſubſide, from which pour it off, and evaporate it to 9 lbs. To this liquor ſeparated from its impurities, and heated in an earthen veſſel, add a warm ſolution of carbonate of ſoda, until the efferveſcence ceaſe: then ſtrain, and ſet the liquor aſide that cryſtals may form. Theſe being removed, add to the liquor, if neceſſary, a little carbonate of ſoda, that the phoſphoric acid may be accurately ſaturated; and diſpoſe it, by evaporation again, to yield cryſtals, as long as theſe ſhall be produced. Finally, let the cryſtals be preſerved in a well-cloſed veſſel.

The Dub. Ph. directs to take of burnt bones, reduced to powder, 5 lbs.; ſulphuric acid, 3½ lbs. Mix the powder with the ſulphuric acid in an earthen veſſel; add, gradually, five pints of water, and agitate the mixture. Digeſt for three days, adding from time to time more water, leſt the materials ſhould become dry, and continue the agitation; then pour over them five pints of boiling water, and ſtrain through a linen rag, pouring on, at intervals, boiling water, until all the acid be waſhed out. Set the liquor apart, that the impurities may ſubſide, from which decant it, and evaporate it to one half; then add 3 lbs. 10 oz. of carbonate of ſoda, diſſolved in a ſufficient quantity of warm water; filter, and obtain cryſtals by repeated evaporation and cooling. The cryſtals are to be preſerved in well-cloſed veſſels.

If the ſalt be not ſufficiently pure, repeat the ſolution and cryſtallization.

A cheaper mode of preparing this ſalt has been given by M. Funcke, a German chemiſt. He adds to the matter of calcined bones diffuſed in water, juſt enough dilute ſulphuric acid to ſaturate the ſmall portion of carbonate of lime it always contains. When the efferveſcence ceaſes, the whole is diſſolved in nitric acid, and as much ſulphate of ſoda added to the ſolution as of bone-aſhes uſed. The whole is then diſtilled, to recover the nitric acid; and the phoſphate of ſoda is ſeparated from the reſidue, which is a mixture of ſulphate of lime and phoſphate of ſoda, by ſolution and cryſtallization.

This ſalt has a purely ſaline taſte, reſembling very much that of common ſalt. Its cryſtals are large, regular, tranſparent, rhomboidal priſms, terminated by three-ſided priſms, having a ſpecific gravity of 1.333, and effloreſcing on expoſure to the air. It is ſoluble in three parts of water at 60°, and in two parts of boiling water; and undergoes the watery fuſion when heated. Its conſtituents, according to Thenard, are, in 100 parts, 19 of ſoda, 15 of phoſphoric acid, and 66 of water. Muriate of barytes, lime, and magneſia, decompoſe this ſalt; and by the ſtrong acids it is converted into ſuperphoſphate of ſoda.

Phoſphate of ſoda is a mild cathartic, excellently adapted for children, and others who have a faſtidious taſte. It may be given diſſolved in gruel or broth, made without ſalt, by which its taſte is very effectually covered. The doſe is from ʒvj to ℥ij. It was introduced into practice by Dr. George Pearſon of London.

The "ſulphate of ſoda" is for the moſt part artificially prepared, and chiefly in the large way, during the manufacture of ſal ammoniac from ſulphate of ammonia and common ſalt. The directions given for preparing it, in the Lond. Ph., are as follow: Take of the ſalt which remains after the diſtillation of muriatic acid, 2 lbs.; boiling water, 2½ pints. Diſſolve the ſalt in the water; then add gradually as much ſubcarbonate of ſoda as will ſaturate the acid. Boil the ſolution until a pellicle appears; and after having filtered it, ſet it apart to cryſtallize. Pour the water from off the cryſtals, and dry them on bibulous paper. The "ſulphate of ſoda" of the Edinb. Ph., formerly "Glauber ſalts," (ſee GLAUBER *Salt*,) is formed by diſſolving in water the acidulous ſalt, which remains after the diſtillation of muriatic acid, and having mixed with it carbonate of lime (chalk) in powder, to remove the ſuperfluous acid, ſetting it apart until the impurities ſubſide; then, having poured off the liquor, filtering it through paper, and reducing it by evaporation, that it may cryſtallize. The Dub. Ph. directs to diſſolve the ſalt, which remains after the diſtillation of muriatic acid, in a ſufficient quantity of boiling water; then to evaporate the filtered ſolution to a proper point, and ſet it apart, that, as it ſlowly cools, cryſtals may be formed. The taſte of this ſalt is at firſt ſimply ſaline, but afterwards very diſagreeably bitter. Its cryſtals are tranſparent, ſix-ſided, irregular, channelled priſms, with dihedral ſummits; effloreſcent, and falling to a white powder, when expoſed to the air. It is ſoluble in 2.86 parts of water at 60°, and 0.8 of boiling water; undergoes the watery fuſion when heated, and in a ſtrong heat is partially decompoſed. According to Kirwan, 100 parts contain 23.52 of acid, 18.48 of alkali, and 58.00 of water; and in the dried ſtate, of 56 of acid, and 44 of water. This ſalt is a very common and uſeful purgative; but, on account of its nauſeous taſte, is not very generally preſcribed by the phyſician. The doſe is from ʒſs to ʒij; but in the effloreſcent ſtate, half of theſe quantities is ſufficient.

The "tartarized ſoda" (ſee CARBONAT *of Soda* and NATRON) is prepared, according to the Lond. Ph., by diſſolving 20 oz. of ſubcarbonate of ſoda in 10 pints of boiling water, and adding gradually 2 lbs. of ſupertartrate of potaſs in powder; filtering the ſolution through paper; then boiling till a pellicle is formed on the ſurface, and ſetting it aſide to cryſtallize; then pouring off the water from the cryſtals, and drying them on bibulous paper.

The "tartrite of potaſs and ſoda," formerly *Sal* RUPELLENSIS (which ſee), is prepared, according to the Edinb. Ph., from carbonate of ſoda and ſupertartrite of potaſs, in the ſame manner as TARTRITE *of Potaſs;* which ſee.

The "tartrate of ſoda and kali," of the Dub. Ph., is formed by diſſolving 20 oz. of carbonate of ſoda in 10 pints of boiling water, and gradually adding 2 lbs. of cryſtals of tartar, reduced to a very fine powder; filtering the ſolution through paper, evaporating it, and ſetting it aſide, that, as it ſlowly cools, cryſtals may be formed. Mr. T. Thomſon obſerves, that of the three appellations of this ſalt, that of the Dublin college is the leaſt exceptionable; the London name conveying an evidently erroneous notion of the preparation, and the Edinburgh college incorrectly denominating it a tartrite.

This ſalt has a bitter ſaline taſte. Its cryſtals are large, regular, tranſparent, hard, rhomboidal, ſix-ſided priſms; very ſlightly effloreſcent, and ſoluble in five parts of water at 60°. It is decompoſed by the ſtrong acids, muriate of barytes, lime, and by a red heat. The conſtituents of 100 parts of this ſalt, according to Schulze, are 41.3 of tartaric acid, 14.3 of potaſs, 13.3 of ſoda, and 31.1 of water.

Tartrate of potaſs and ſoda is a cooling and not very unpalatable cathartic. It was introduced into practice by M. Seignette, an apothecary of Rochelle, and the preparation kept a ſecret until it was diſcovered and publiſhed by Boulduc and Geoffrey in 1731. It operates moderately, and without exciting much irritation: hence it is well ſuited to nephritic and puerperal caſes. The doſe is from ʒj to ℥jſs, diſſolved in any convenient vehicle. Woodville. Thomſon's Lond. Diſp.

SODA, in *Medicine,* a word of Arabic origin, nearly ſynonimous with *cardialgia,* and *heart-burn,* ſignifying any ſenſe of burning heat in the ſtomach, ariſing from acidity or acrid humours. See CARDIALGIA and INDIGESTION.

The term *ſoda* has, however, been conſidered by ſome writers as alſo ſignifying heat and pain of the head.

SODA, in *Geography,* a town of Arabia, in the province of Nedsjed; 180 miles E. of Medina.

SODA, in *Natural Hiſtory.* See KALI.

SODA *Subethica,* a term uſed to expreſs a heavy and dull pain in the head.

SODADA, in *Botany,* from its Arabic name *Sodâd.* Forſk. Ægypt-Arab. 81. Juſſ. 243.—A genus of the natural order of *Capparides,* which is undoubtedly diſtinct, and may perhaps be tolerated under the above appellation, though of avowedly barbarous origin, like *Aucuba,* and one or two ſimilar names, of eaſy pronunciation. We do not, however, wiſh to ſanction any ſuch, but leave them to future opportunities of a thorough and authentic reform. In the preſent inſtance, at leaſt, we attempt no amendment, becauſe we have not materials to deſcribe the genus under conſideration. Colonel Hardwicke has brought, from the Eaſt Indies, either Forſkall's identical plant, or another ſpecies of the ſame genus. Forſkall deſcribes his as follows.

S. *decidua.* Calyx of four unequal leaves. Petals four, unequal. Stamens inclining. Capſule ſtalked.

A diffuſe *ſhrub,* with diſtant, alternate, ſpreading *branches,* about two inches long, with a pair of ſhort awl-ſhaped *ſpines* at each bud. *Leaves* ſeſſile, oblong, deciduous, rarely preſent. *Flower-ſtalks* between the ſpines, ſingle-flowered, three together. *Flowers* red. *Calyx* coloured, deciduous; its upper ſegment very large, gibbous, compreſſed, often ſplit at the ſide; the reſt equal, linear-lanceolate, fringed. Two upper *petals* ovate, pointed, flat, at firſt hidden under the upper leaf of the calyx; two lower narrower, alternate with its lower leaves, downy at the under ſide and edges. *Stamens* eight, unequal, thread-ſhaped, longer than the petals, browniſh-green. *Germen* globoſe, with four furrows on a ſtalk as long as the ſtamens. *Style* awl-ſhaped. *Stigma* acute. *Fruit* red, bigger than a hazel-nut, eatable when dreſſed before it is ripe. This ſhrub is common throughout the country of Yemen.

SODALES AUGUSTALES. See AUGUSTALES.

SODALITE, in *Mineralogy,* a ſtone which derives its name from the large portion of mineral alkali that enters into its compoſition. Its colour is a blueiſh-green. It occurs both cryſtallized and maſſive: the cryſtals are dodecahedrons, with rhomboidal faces. The ſtructure is lamellar, with joints in two directions. The fracture is conchoidal: it has a ſhining and reſinous luſtre, but the luſtre of the freſh fracture is vitreous; it is tranſlucent, and yields with difficulty to the knife. The ſpecific gravity is 2.37. It is infuſible by the blowpipe.

The conſtituent parts of ſodalite, as given by different chemiſts, vary.

Silex	36	to	38
Alumine	27	to	32
Soda	23	to	25
Oxyd of iron	¼	to	1
Lime	0	to	2
Muriatic acid	3	to	7

SODALITIUM, among the Anglo-Saxons, was the name of a voluntary aſſociation, the object of which was the perſonal ſecurity of thoſe who joined in it, and which the feebleneſs of government at the time rendered neceſſary. Among other regulations, which are contained in one of theſe ſtill extant, the following deſerves notice: If any aſſociate ſhall either eat or drink with a perſon who has killed any member of the ſodalitium, unleſs in the preſence of the king, the biſhop, or the count, and unleſs he can prove that he did not know the perſon, let him pay a great fine. Hicks Diſſ. Epiſt. apud Theſ. Ling. Septentr. vol. i. p. 21.

SODBURY, CHIPPING, anciently *Sopeberie,* in *Geography,* a ſmall pariſh, containing only 90 acres, and market-town, in the lower diviſion of the hundred of Grombald's-Aſh, in the county of Glouceſter, England, is ſituated 12 miles N. from Briſtol, 30 S. from Glouceſter, and 113 W. from London, at the foot of the Great Howby hill, a continuation of that chain which extends from north to ſouth through the county. This, and the two adjoining pariſhes of the ſame name, were ſo called from the *berie,* or camp, which is found on the ſummit of Old Sodbury. Chipping diſtinguiſhes it as a market-town, and was firſt uſed when the market was eſtabliſhed, in the reign of Henry III. The town conſiſts of one long ſtreet, and is the great thoroughfare between Briſtol and the eaſtern part of the county. The church conſiſts of a nave and two aiſles, with

with an embattled tower at the weſt end. A weekly market is held on Thurſdays, and two fairs yearly. By a charter of incorporation, granted by king Charles II. in 1681, the government of the borough was veſted in a mayor, ſix aldermen, and twelve burgeſſes, with a high ſteward, recorder, and town-clerk; and at the ſame time was granted the privilege of holding pleas of all manner of perſonal ſuits and debts under five pounds, ariſing within the borough. But in 1688, at the requeſt of the inhabitants, from what cauſe is not now remembered, the charter was annulled by proclamation; and from that period the ancient government by a bailiff was revived, who is annually choſen by the lord of the manor out of three perſons, returned to him at the court-leet. Two eſtates, called the Stub-Ridings and Meadow-Ridings, were anciently granted by two lords of the manor, in the reigns of Henry II. and John, to the bailiffs and bailiff-burgeſſes, for the following purpoſes. The former, conſiſting of about 100 acres, is granted for ſummer-paſture under certain regulations for ſixty-eight cow-beaſts, to as many perſons as have been inhabitants of the town for fourteen years. The latter is divided into eighty-one lots, beſides two others, called the Bailiff's and Hayward's piece. Each of theſe, containing rather more than a ſtatute acre, is held by a leſſee for his own life, and the life of his widow. Out of theſe eſtates the lord of the manor receives an annual payment of 5*l.*, and the vicar of Old Sodbury 1*l.* 13*s.* 4*d.* in lieu of tythes. The bailiff is entitled to fifty ſhillings yearly, for which, by ancient cuſtom, he provides an ox and two barrels of ale, on St. Stephen's day, for the inhabitants.

A guild was founded in this borough, dedicated to St. Mary, in the reign of Henry VI., of which John Glover was the laſt incumbent. The lands were granted, in 1558, to the burghers of Sodbury, part for a town-hall, and part for an alms-houſe. A free-ſchool is ſupported in this pariſh, by the profits of lands in different pariſhes. In the population returns to parliament in the year 1811, the inhabitants of this pariſh were ſtated to be 1235, occupying 236 houſes. In the ſanguinary reign of Mary, John Pigott was burnt here for his adherence to the Proteſtant religion.

The manor was granted by the Conqueror to Odo, earl of Champagne, whoſe grandſon, William, granted the privilege of paſture-common in the Riding before mentioned, the original of which is ſtill in exiſtence. About the ſame time, William Green of Sodbury gave Gaunt's Fields to the burgeſſes; and Jurdan Biſhop, who was lord of the manor of Little Sodbury, granted them common of paſture for cattle in Dymerſhed and Norwood. The manor, which by ſucceſſive marriages has been poſſeſſed by various families, is now held by that of Hartley.

In the high lands, eaſt of the town, are found a great variety of belemnites, nautilites, of the ribbed ſort; and weſt of the town, ſome veins of ſulphate of ſtrontian have been diſcovered.

Little Sodbury is a pariſh adjoining Chipping Sodbury, and conſiſts of about 900 acres of land, the greater part of which is appropriated to the dairy ſyſtem. On the edge of a hill, in this pariſh, is a large encampment of an oblong form, compriſing an area of about 200 yards from eaſt to weſt, and 300 from north to ſouth. This was probably formed by the Romans; and according to Leland, it was occupied by Edward IV.'s army, previous to the battle of Tewkeſbury.

Old Sodbury is another pariſh adjoining the former, on the north-eaſt, and conſiſts of 3000 acres of land, the greater part of which is paſture.

Dodington, three miles ſouth-eaſt of Sodbury, is the magnificent ſeat of Chriſtopher Codrington, eſq. who has long been engaged in building a ſpacious and ſplendid manſion here, from the deſigns of the late James Wyatt, eſq. architect. Rudge's Hiſtory of the County of Glouceſter, 2 vols. 8vo. 1803.

SODDER, or SODER. See SOLDER.

SODDERING. See SOLDERING.

SODDING *of Brick.* See BRICK.

SODDOMA, IL, in *Biography*, the cognomen of Giovanni Antonio Razzi, a native of Vercelli, in Piedmont, born about the year 1479. He was inſtructed in painting by Giacomo dalle Fonte; but his chief object of ſtudy was the ſtyle of L. da Vinci. He was employed by Julius II. to paint the chambers of the Vatican; but the charms of Raphael's firſt productions in that palace were the ſignal for the obliteration of all other works there: among them Il Soddoma's. Other pictures, which he painted for Agoſtino Ghigi in the Farneſina, were more fortunate, and yet remain. Their ſubjects are taken from the hiſtory of Alexander the Great, and though inferior to the works of Lionardo, yet they exhibit very conſiderable talent, many beauties of perſpective, and much playful imagery.

After he left Rome, he had conſiderable employment at Sienna, and there his beſt productions are to be found, in which he has combined the excellent qualities of the beſt artiſts of his day. He died in 1554.

SODENKYLA, in *Geography*, a town of Swediſh Lapland; 110 miles N.N.E. of Tornea. N. lat. 67° 25′. E. long. 26° 14′.

SODERALA, a town of Sweden, in Helſingland; 3 miles S.W. of Soderhamn.

SODERBY, a town of Sweden, in Jamptland; 60 miles N. of Froſon.—Alſo, a town of Sweden, in Upland; 40 miles N.N.E. of Stockholm.

SODERHAMN, a ſea-port town of Sweden, in the province of Helſingland, ſituated at the mouth of a river, near the gulf of Bothnia, firſt built by gunſmiths and copperſmiths, and erected into a town in the year 1620. The houſes are mean, but the church handſome. The trade of this place is conſiderable in arms, linen, butter, timber, flax, &c.; 20 miles N. of Geffle.

SODERKIOPING, a town of Sweden, in the province of Eaſt Gothland. This is a ſtaple town, ſituated on a navigable river, and one of the moſt ancient cities in Gothland. It had formerly its own municipal laws, and was in a much more flouriſhing condition than it is at preſent. Two kings were crowned, and in 1595 a diet was held in this town. It has at preſent but two churches; 10 miles S.S.E. of Nordkioping. N. lat. 61° 18′. E. long. 16° 54′.

SODERON, a ſmall iſland near the coaſt of Sweden, in the Alands Haf. N. lat. 60° 15′. E. long. 8° 14′.

SODERSKARBAK, a ſmall iſland in the gulf of Finland. N. lat. 60° 5′.

SODERTELGE, or *Soder Telge*, a town of Sweden, in the province of Sudermanland, ſituated between the ſea and the Maeler lake. About two miles and a half diſtant from this town, at a place called "Aegelſtowyk," is a good harbour. Sodertelge was formerly a ſtaple town, and in a flouriſhing condition; and there is ſtill a manufacture of worſted and ſilk ſtockings in this town. In the year 1719, Sodertelge was burnt by the Ruſſian army, but has ſince been rebuilt; 16 miles W.S.W. of Stockholm. N. lat. 59° 8′. E. long. 18° 28′.

SODE-SHOOTS, in *Botany*, a name given by ſome to the tree, whoſe inſpiſſated juice is the gum tacamahacca of the ſhops.

SODFORS, in *Geography*, a town of Sweden, in Weſt Bothnia; 18 miles N.W. of Umea.

SODIA, a town of Arabia, in the province of Hedsjas; 70 miles S.S.E. of Mecca.—Alſo, a mountain of Arabia, in the province of Hedsjas; 60 miles S. of Mecca.

SODINUS, in *Ancient Geography*, a navigable river of Aſia, which runs into the Cophes, according to Pliny.

SODIUM, in *Chemiſtry*, a ſimple body and a metal. This was diſcovered by ſir Humphrey Davy in the year 1807. He had a few days before found that potaſh was a compound of a peculiar metal combined with oxygen, and he now found that ſoda conſiſted of a metallic ſubſtance combined with oxygen. He firſt produced it by expoſing ſoda to the action of the Galvanic battery.

It is now obtained by fuſing ſoda or muriate of ſoda with potaſſium. The potaſſium combines with the oxygen in the ſoda, and with the chlorine in the ſalt, leaving pure ſodium.

This metal is white, reſembling ſilver; and having the ſame metallic luſtre.

Its ſpecific gravity is between 9 and 10, water being 1. In the common temperature it is malleable.

It aſſumes the liquid form at 200° of Fahrenheit, and is volatile at a red heat.

If expoſed to the air it would ſoon loſe its luſtre, by combining with oxygen, and in a little time would be converted into ſoda.

It is preſerved in naphtha, like potaſſium.

When heated in oxygen or chlorine, it burns with great brilliancy.

When thrown upon water, it does not ſink but runs along the ſurface, the motion being occaſioned by the rapid eſcape of hydrogen gas, from its decompoſing the water with great rapidity. The floating maſs is ſeen to diminiſh as it runs along, till it diſappears, when, as may be expected, the water is found to contain a ſolution of ſoda.

Sodium, like other metals, is a conductor of electricity.

Sodium combines with two doſes of oxygen. The one is that which conſtitutes ſoda; the other is of an orange colour, firſt obſerved by ſir Humphrey Davy; but for the particulars of its nature we are indebted to M. M. Gay Luſſac and Thenard.

Soda, in its pure ſtate, is a ſolid of a greyiſh-white colour, very hard, and breaks with a ſmooth fracture. In this ſtate it requires a ſtrong heat for its fuſion. When expoſed a little to the air, it abſorbs water, aſſumes a whiter colour, and becomes much more fuſible by heat. Its volatility is alſo increaſed at the ſame time. In this ſtate, as is the caſe with lime, potaſh, and many of the metallic oxyds, it is called an hydrate.

The peroxyd of ſodium is formed by burning ſodium in oxygen gas, an exceſs of the gas being preſent.

It is of a deep orange colour, and fuſes at a much leſs heat than ſoda.

If thrown into water, one atom of oxygen eſcapes in the form of gas, leaving pure ſoda, which diſſolves in the water. This proves how cloſely the exceſs of oxygen is held. This, however, is more conſpicuouſly ſhewn in its action upon combuſtible bodies, with which it deflagrates.

The atom of ſodium has been conſidered 22; hydrogen being 1, and oxygen 7.5; hence the protoxyd would be 29.5, and the peroxyd 37. But from the experiments of Gay Luſſac and Thenard, it appears that the oxygen in the ſoda is to that in the peroxyd as 1 to $1\frac{1}{2}$, or as 2 to 3; but as the exiſtence of half atoms would be abſurd, the atom of ſodium muſt be conſidered as equal to 44; the protoxyd will then be 51.5; the deutoxyd, which is ſoda, will be $44 + 2 \times 7.5 = 59$, and the peroxyd $44 + 3 \times 7.5 = 81.5$.

Soda combines with ſulphur, and is called ſulphuret of ſoda. It poſſeſſes properties differing but little from the ſulphuret of potaſh. It is formed by fuſing ſulphate of ſoda with common ſaw-duſt. Like ſulphuret of potaſh, when thrown into water, it firſt diſſolves, and decompoſing that fluid, the remaining ſulphuret combines with the hydrogen in its naſcent ſtate to form hydrogen with ſulphuret of ſoda. This forms a greeniſh-coloured fluid, having the ſmell of ſulphuretted hydrogen. The phoſphuret of ſoda is alſo ſimilar to the phoſphuret of potaſh. See POTASH.

Sodium alſo combines with ſulphur and phoſphorus. When ſodium and ſulphur are heated together in a veſſel filled with vapour of naphtha, they unite with all the ſigns of ſplendid combuſtion, the ſulphur ſupplying the place of oxygen. The compound is of a grey colour, producing ſulphate of potaſh by expoſure to the air. Their proportions ought to be 44 ſodium to 15 ſulphur for the firſt, and 44 to 30 for the ſecond ſulphuret.

Sodium has a ſimilar effect upon phoſphorus, by which the phoſphuret of ſodium is produced. It has no known action upon carbon, azote, or hydrogen.

Sodium combines with many of the metals, forming peculiar alloys. With potaſſium, in a ſmall proportion, it forms an alloy, which, agreeably to other alloys, is more fuſible than either of the metals. The alloy is of leſs ſpecific gravity than either of the metals, a circumſtance not common with other metallic alloys. The latter fact goes to prove that there is not a great affinity between the two metals.

One part of ſodium renders 40 of mercury ſolid, at the common temperature. When they combine, heat is diſengaged. It alſo combines with tin, without changing its colour. When theſe alloys are expoſed to the air, the ſodium is gradually ſeparated, by combining with the oxygen of the atmoſphere.

Salts of Soda, or its Compounds with the Acids.—Under this head we ſhall compriſe the muriate of ſoda, although, in ſtrict propriety, we might have been expected to have treated this compound under the action of ſodium upon *chlorine.*

Sulphate of Soda.—This ſalt is found native in moſt ſea-vegetables: it has been called Glauber ſalt. It may be eaſily formed by adding ſulphuric acid to the cryſtallized carbonate of ſoda, till the efferveſcence ceaſes, and the ſolution is neither acid nor alkaline.

On evaporation and cooling, it eaſily cryſtallizes into ſix-ſided priſms of a pearly appearance. Their taſte is cooling and rather bitter. At the temperature of 60° it diſſolves in leſs than three times its own weight of water, and in much leſs than its own weight of boiling water. When a ſolution of this ſalt is concentrated till it has ſomething leſs than half its own weight of water, and carefully ſet by to cool, it will not cryſtallize; but if a tremulous motion be given to the veſſel, or a cryſtal of the ſame ſalt dropped into it, the whole ſuddenly cryſtallizes, exhibiting a beautiful appearance. When the cryſtals are expoſed to the air, they loſe their water of cryſtallization, and aſſume the form of white powder. In this change they loſe about 60 *per cent.* of their weight, as will be ſeen in their analyſes.

According to Kirwan, it is compoſed of

Sulphuric acid - -	23.52
Soda - - - -	18.48
Water - - -	58.
	100

According to Bergman,

Acid	27
Soda	15
Water	58
	100

Wenzel's analyſis of the dry ſalt is,

Acid	55.7
Soda	44.3
	100

Kirwan's analyſis of ditto,

Acid	56
Soda	44
	100

It appears that this ſalt conſiſts of two atoms of acid to one of ſoda, and 20 atoms of water. This, if hydrogen be 1, will be 37.5 × 2 acid + 59 ſoda + 170 water = 304. Reduced to the hundred, it will be

Acid	19.4
Soda	24.6
Water	56.
	100

Nitrate of Soda.—This ſalt has been called *cubic nitre,* from having the general properties of nitrate of potaſh, but differing in the form of its cryſtals, which are of a cubical, or rather rhomboidal form.

It may be formed by ſaturating pure carbonate of ſoda with nitric acid.

On evaporation and cooling, it forms rhomboidal cryſtals, the ſpecific gravity of which is 2.0964, water being 1.

Theſe cryſtals diſſolve in three times their weight of water at 60°, and in leſs than their own weight of boiling water.

With inflammable bodies and heat, it exhibits phenomena ſimilar to thoſe of nitre: but it is inferior to that ſubſtance in forming gunpowder with charcoal and ſulphur.

Its proportions, according to Bergman, are

Nitric acid	43
Soda	32
Water	25
	100

According to Kirwan, in the dry ſtate,

Nitric acid	57.55
Soda	42.34
	99.89

This ſalt appears to be compoſed of one atom of acid and one of ſoda, in the dry ſtate, or 50.5 acid and 44 ſoda = 94.5. This will give

Nitric acid	53.5
Soda	46.5
	100

Muriate of Soda.—This ſalt, which is the common culinary ſalt in a ſtate of purity, is a component part of almoſt all animal matter; nor is there perhaps a vegetable that does not yield ſome portion of it.

It exiſts ready formed in the ſea, and forms entire mountains in the ſubſtance of the globe. It is from the native ſalt that all the muriatic acid is obtained. It is never formed by art, but the pure ſalt may be obtained by adding carbonate of ſoda to the ſalt in ſolution; then evaporate it to obtain cryſtals; theſe are of a cubic form, and pure muriate of ſoda.

According to the prevailing view now taken of this ſalt, it is a compound of ſodium and chlorine, or what was called oxymuriatic acid. Hence it is not conſidered as a ſalt, thoſe bodies being compounds of an acid and an oxyd. The ſubſtance in queſtion is believed to be a compound of ſodium, an inflammable body, combined with another body, having more the properties of oxygen than any other body. Muriate of ſoda is, therefore, conſidered as being more allied to an oxyd than a compound of two, the chlorine acting the part of oxygen. It is called by ſir Humphrey Davy *ſodane,* by Dr. Thomſon *chloride of ſodium,* and by the French chemiſts *chloruret of ſodium.* The taſte of this ſalt may be called the ſtandard of that ſenſation we call *ſalt.* Its ſpecific gravity is 2.12; it is ſoluble in about three times its weight of water at 60°, and nearly in the ſame quantity of boiling water.

It is unchanged by expoſure to the air. The moiſt ſtate in which it is frequently found in commerce, ariſes from the preſence of a little muriate of lime, which the pureſt native ſalt always contains; but it is more abundant in the ſalt obtained from ſea-water.

It is compoſed, according to Bergman, of

Muriatic acid	52
Soda	42
Water	6
	100

According to Kirwan, when dried at 80°,

Acid	38.88
Soda	53.
Water	8.12
	100

Sir Humphrey Davy conſiders it a compound of 2 atoms of chlorine and 1 of ſodium, or 2 × 33 chlorine + 44 ſodium = 110. This will be

Chlorine	60
Sodium	40
	100

See the article SALT.

Phoſphate of Soda.—This ſalt has been longer known than phoſphorus. It exiſts ready formed in urine, from which it was extracted, and called *ſal mirabile perlatum,* or wonderful perlated ſalt. It was ſo called from its cryſtals having a pearly appearance. This ſalt, with exceſs of acid, was conſidered by Prouſt as a peculiar acid, which he called the perlated acid. But it was ultimately found by Klaproth, and afterwards by Scheele, to be a compound of ſoda with the phoſphoric acid.

Dr. Pearſon firſt prepared it artificially, and introduced it into medicine as a purgative. He diſſolved 1400 grains of cryſtallized carbonate of ſoda in 2100 grains of water, and added gradually 500 grains of phoſphoric acid, of the ſpecific gravity 1.85. This ſolution he boiled for a few minutes, and filtered it while hot. The ſolution was ſet out in a cool place to cryſtallize.

This ſalt is often made by ſaturating ſoda with the ſuperphoſphate of lime obtained from bones by ſulphuric acid, and is never ſufficiently free from lime.

The acid ſhould be obtained by burning phoſphorus, and the ſoda uſed in the ſtate of well-formed cryſtals, when the pure ſalt is required.

It cryſtallizes in the form of rhomboidal priſms, terminating with three-ſided pyramids.

It effloreſces by expoſure to the air.

Its taſte is very like muriate of ſoda, but more mild and agreeable.

It is ſoluble in four parts of cold, and in about three parts of boiling water.

When expoſed to heat it firſt undergoes the watery fuſion. When heated to redneſs, it melts into a white enamel. From this property it has been propoſed as a ſubſtitute for borax, in the ſoldering of metals: it alſo reſembles the ſame ſubſtance in forming coloured glaſſes with metallic oxyds.

It is partially decompoſed by the ſulphuric, nitric, and muriatic acids, leaving it in a ſtate containing double its original quantity of acid. This is called the ſuperphoſphate of ſoda. It was this ſalt which Prouſt took for a peculiar acid. It is more ſoluble in water than the phoſphate, and does not eaſily cryſtallize.

Phoſphate of ſoda has not been analyſed: ſince, however, the weight of an atom of phoſphorus is 13, and phoſphoric acid $13 + 2 \times 7.5 = 28$, then phoſphate of ſoda will be $2 \times 28 + 59$, or

Soda - - - - -	51
Acid - - - - -	49
	100

Fluate of Soda.—This ſalt may be formed by adding fluoric acid to carbonate of ſoda, till the efferveſcence ceaſes.

On evaporation, it forms into cubic cryſtals. Theſe are ſparingly ſoluble in water, and have an aſtringent bitter taſte.

Borate of Soda.—This is a ſalt with half the quantity of acid which the borate contains; it is known in commerce and in the arts by the name of borax. The latter ſubſtance is extracted from a ſubſtance called tincal: the true borate is, therefore, not uſed, but the ſub-borate or borax.

Sub-borate of ſoda is cryſtallized in hexagonal priſms, with two ſides broader than the reſt. It is ſemitranſparent. Its ſpecific gravity is 1.74. It is ſoluble in twelve parts of cold water, and in ſix of boiling water. It has a ſweetiſh taſte, and rather alkaline. When expoſed to the air, it is ſoon reduced to a white powder, with much loſs of weight. This ariſes from the eſcape of the water of cryſtallization. Artiſts are apt to uſe it too plentifully in this ſtate, and fancy that its proper virtue is gone; but the white powder is equally valuable with the ſalt for all purpoſes. When the ſame change is brought about by heat, the borax is ſaid to be calcined. If a ſtrong heat be given to it in a crucible, it melts into a tranſparent glaſs. It is frequently uſed in forming choice ſpecimens of ſham cryſtals, by fuſion with flint, lead, and manganeſe. The compoſition of borax, according to Bergman, is,

Acid - - - - - - -	39
Soda - - - - -	17
Water - - - - -	44
	100

The acid is obtained from this ſalt by diſſolving it in hot water, and then adding ſulphuric acid. As the liquid cools, ſmall ſcaly cryſtals are precipitated, which are the pure boracic acid.

The baſe of this acid has been diſcovered ſince the commencement of this work, and even ſince this acid has been treated of: we, therefore, feel it our duty to give ſome account of it here.

When boracic acid, ſlightly moiſtened, is expoſed between two plates of platina, one being connected with the copper ſide of a Galvanic battery, and the other with the zinc ſide, the oxygen of the acid is attracted to the zinc or poſitive ſide, and the inflammable baſe to the copper or negative ſide. This is a dark coloured ſubſtance, which becomes detached from the reſt of the maſs, and is the baſe in queſtion. This experiment was firſt made by ſir Humphrey Davy, in March 1808, about the time that he diſcovered potaſſium and ſodium. In the November following it appears that he, as well as Meſſrs. Gay Luſſac and Thenard, obtained this baſe by heating boracic acid with potaſſium. The latter chemiſt alſo ſucceeded in recompoſing the acid. This ſubſtance has been called *boron* by ſir Humphrey Davy, which name it ſtill retains.

Boron is an opaque ſubſtance of a dark olive colour.

It is not fuſible or volatile at any known temperature. When heated in the open air, it burns by abſorbing oxygen, and is converted into dry boracic acid. In pure oxygen gas it undergoes more vivid combuſtion, giving out bright ſcintillations. The maſs becomes coated with boracic acid, and the remainder of the baſe is found unchanged in the cruſt.

It is a non-conductor of electricity, a proof that it is not of a metallic nature.

It is inſoluble in water.

The proportion of oxygen in boracic acid is not yet known. The cruſt of boracic acid, which forms on boron when it is burned, ſecures the remainder from the oxygen, ſo as to render the reſult ambiguous.

Sir Humphrey Davy judges, from the quantity of potaſſium required for the decompoſition of the acid, that it contains two-thirds its weight of oxygen. Gay Luſſac and Thenard, from treating boron with nitric acid, make it to contain one-third its weight of oxygen; but this reſult is not to be relied upon, ſince boracic acid is volatile both with water and the nitric acid.

Sir Humphrey Davy found that 90 parts of potaſh were required to neutralize 160 of boracic acid. This will give 80 for the weight of the atom of boracic acid, potaſh being 45, and hydrogen 1. If, according to ſir Humphrey, it contains two-thirds of oxygen, then the atom of boron will be 27.

Dr. Thomſon, from the experiments of Berzelius, which are in ſome meaſure corroborated by thoſe of ſir Humphrey Davy, makes the atom of boron 5.5, hydrogen being 1. This is the weight of the atom of carbon, to which boron ſeems in other reſpects allied. If, like carbon, it combines with two atoms of oxygen, then boracic acid will be

$5.5 + 7.5 \times 2 = 20.5$. Sir Humphrey's atom, which is 80, is nearly a multiple of this number.

Carbonate of Soda.—This is the ſalt known by the name of ſal ſoda. It exiſts ready formed in barilla and kelp, and is eaſily obtained by ſolution and evaporation, allowing it to cryſtallize ſlowly. It cryſtallizes in flat rhomboidal priſms. It is ſoluble in two parts of cold water, and in leſs than its own weight of boiling water. Like the ſulphate of ſoda, it effloreſces in the air, and aſſumes the form of white powder.

When heated, it melts in its own water of cryſtallization. This ſoon eſcapes; and if the heat be raiſed, one half of the carbonic acid probably eſcapes.

According to Bergman, its compoſition is,

Soda - - - -	20
Acid - - - -	16
Water - - - -	64
	100

According to Klaproth, it contains,

Soda - - - -	22
Acid - - - -	16
Water - - - -	62
	100

According to Kirwan, in cryſtals,

Soda - - -	21.58
Acid - - -	14.42
Water - - -	64
	100

In the dry ſtate,

Soda - - -	59.86
Acid - - -	40.14
	100

This ſalt is compoſed of 2 atoms of acid, 1 of ſoda, and 20 of water; or 41 acid, 59 ſoda, and 170 water. This, in 100, will be,

Soda - - -	21.8
Acid - - -	15.2
Water - - -	63
	100

This ſalt, although called a carbonate, is evidently a bicarbonate of ſoda; and the ſalt, which reſults from heating this, muſt be conſidered a carbonate.

There is another compound, with a ſtill greater proportion of carbonic acid, which is either a tricarbonate or a tetracarbonate of ſoda.

Arſeniate of Soda.—This is a ſalt little known, but believed to have the general properties of arſeniate of potaſh. See that ſalt under SALTS.

Acetate of Soda.—This ſalt may be formed by ſaturating carbonate of ſoda with acetic acid. It cryſtallizes in priſms reſembling ſulphate of ſoda. It is ſoluble in about three parts of water at 60°. It does not cryſtallize but with exceſs of alkali.

The other ſalts of ſoda are too little known to be important.

SODMERE POINT, in *Geography*, a cape on the S. coaſt of the Iſle of Wight. N. lat. 50° 38′. W. long. 1° 16′.

SODOM, in *Ancient Geography*, the chief city of the Pentapolis, which comprehended the five cities called Sodom, Gomorrah, Zeboim, Admah, and Zoar or Segor. The four former were deſtroyed on account of their wickedneſs by fire from heaven, A.M. 2107 or B.C. 1897; but the latter, though ſentenced to the ſame fate, was ſpared at the interceſſion of Lot. Sodom had been his dwelling-place, and the plain on which Sodom and the other cities ſtood was pleaſant and fruitful, like an earthly paradiſe, but after their deſtruction it was overflowed by the waters of the river Jordan, which thus formed the "Dead ſea," or "lake of Sodom," or the "ASPHALTITE *Lake*," which ſee. A French geographer, ſetting aſide the miraculous part of this event, aſcribes it to a volcanic eruption, and he conceives the lake to have been the crater of the volcano; but it is ſufficient to obſerve that this opinion contradicts the hiſtorical narration of this event.

In the time of Joſephus the ruins of theſe cities were ſtill in being. Strabo (Geog. l. xv.) alſo ſpeaks of the ruins of Sodom, which were 60 furlongs in compaſs, and were viſible on the ſhore of the Dead ſea. The "Notitia" expreſsly mentions Sodom as an epiſcopal city: and we find one Severus, a biſhop of Sodom, among the biſhops of Arabia who ſubſcribed to the firſt council of Nice. Reland, however, cannot allow that Sodom was ever rebuilt, and he thinks that the word Sodom, among the ſubſcriptions to the council of Nice, to have been an error of the copiers. Calmet is of a different opinion. The record, he ſays, is very circumſtantial: it puts the epiſcopal city of Sodom between Thamar and En-geddi. Stephanus, the geographer, places En-geddi near Sodom. Hence Calmet concludes, that the city of Sodom was rebuilt, either in or near its former ſituation; for though it appears probable that it was not covered by the waters of the Dead ſea, and that it ſtood on the ſhore of this ſea, yet, ſays Calmet, "I would not ſtrenuouſly oppoſe the contrary opinion."

SODOMY, the unnatural crime of buggery; thus called from the city of Sodom, which was deſtroyed by fire for the ſame. This is uſually, and very juſtly, denominated the "crime againſt nature," when committed with man or beaſt:—a crime, which ought to be ſtrictly and impartially proved, and then as ſtrictly and impartially puniſhed. The delicacy of our Engliſh law treats it, in its very indictments, as a crime not fit to be named; "peccatum illud horribile, inter Chriſtianos non nominandum." The edict of Conſtantius and Conſtantine obſerves a ſimilar taciturnity; "ubi ſcelus eſt id, quod non proficit ſcire, jubemus inſurgere leges, armari jura gladio ultore, ut exquiſitis pœnis ſubdentur infames, qui ſunt, vel qui futuri ſunt rei."

The Levitical laws adjudged thoſe guilty of this execrable evil to death, Lev. xviii. 22, 23. xx. 15, 16; and the civil law aſſigns the ſame puniſhment to it. Our ancient law commanded ſuch miſcreants to be burnt to death (Brit. c. 9.), though Fleta ſays (l. i. c. 37.) they ſhould be buried alive; either of which puniſhments was indifferently uſed for this crime among the ancient Goths. At preſent our laws make it felony. (25 Hen. VIII. c. 6. 5 Eliz. c. 17.) And the rule of the law is, that if both are arrived at years of diſcretion, "agentes et conſentientes pari pœna plectantur." 3 Inſt. 59.

SODRA BARKER, in *Geography*, a town of Sweden, in Dalecarlia; 40 miles S. of Fahlun.

SODRES, in *Ancient Geography*, a people of India, in the number of thoſe who were ſubdued by Alexander, according to Quintus Curtius, l. viii.

SODUCENA, a country of Aſia, in the Greater Armenia, S. of Colthene, according to Ptolemy.

SODUS, Great, in *Geography*, a large townſhip of America, in the N.E. corner of Ontario county, in the ſtate of New York, with a poſt-office called "Troupville," bounded N. by lake Ontario, E. by Seneca county, S. by Lyons, and W. by Williamſon and Palmyra; about 18 miles ſquare, and including a great part of Sodus bay. The ſurface is undulated with hillocks and vallies, in a N. and S. direction, and the ſoil is good and well watered. The timber is luxuriant, and conſiſts of the ſugar-maple, beech, oak, hickory, elm, aſh, linden or baſs-wood, cherry, tulip-tree or poplar, butternut, &c. Crops of wheat, rye, maize, hemp, flax, oats, and the common graſſes, ſucceed well, as do alſo the common fruits of the country. In the N.E. corner of Sodus is Great Sodus bay, reckoned the beſt harbour on the S. ſhore of the Ontario; and on an elevated point of land, projecting into the bay, the poſt-village of Troupville is very eligibly and handſomely ſituated, 212 miles from Albany, and about 30 N.E. of Canandaigna. Sodus has two griſt-mills, five ſaw-mills, one fulling-mill, and a conſiderable number of the common mechanical branches of manufacture for the convenience of the inhabitants. Here are two meeting-houſes, one for Preſbyterians and one for Baptiſts, and ſeveral ſchool-houſes. Iron ore has been found here. The firſt ſettlements in this town commenced in 1790, by two German families from the Mohawk river; and though the progreſs of population was ſlow, it amounted, by the cenſus of 1810, to 1957 perſons, and 343 families. N. lat. 43° 10′. W. long. 77° 5′.

Sodus, *Little*, a town of New York, in Albany, on the S. ſide of lake Ontario; 12 miles E. of Great Sodus.

SOEBORG, a town of Denmark, in the iſle of Zealand, ſeated on an iſland in a freſh-water lake. Near this town is a triangular pillar, with Latin, Daniſh, and German inſcriptions, erected in the year 1738, in honour of Frederick IV. and Chriſtian VI., for having ſtopped the progreſs of flying ſand, which overwhelmed one tract of land and village after another, and threatened the beſt part of Zealand with deſolation. In the reigns of theſe two monarchs this evil was reſtrained under the inſpection of the prefect Frederick Von Gram, by the addreſs of John Ubr. Rohl. This ſandy waſte is now covered with verdure, and appears like a fine meadow; 9 miles W.N.W. of Helſingoer.

SOELBO, a town of Norway, in the province of Drontheim; 20 miles E. of Drontheim.—Alſo, a lake, 18 miles S.E. of Drontheim.

SOELENGAT, a town of Norway, in the province of Bergen; 112 miles N. of Bergen.

SOEST, or Zoest, Gerard, in *Biography*, was a native of Weſtphalia, born about the year 1637. He acquired the art of painting in his own country, but practiſed principally in this, whither he came rather before the period of the reſtoration. His portraits have a conſiderable portion of truth and animation, wrought in a finiſhed manner, and with great warmth and glow of colour; ſo much ſo as to claſs him among the better rivals of ſir Peter Lely. He was moſt ſucceſsful in his portraits of men, among whom he had a very conſiderable ſhare of employment; but the more graceful and engaging pencil of ſir Peter ſecured the charms of the ſofter ſex to himſelf. Soeſt died at the early age of 44.

Soest, in *Geography*, a town of Germany, in the county of Mark, formerly one of the Hanſe towns, enjoying imperial privileges and the right of coining money. Its extent is large, and contains ſeveral churches. It was the place in which ſeveral of the ſucceſſors of Charlemagne reſided; 22 miles E. of Dortmund. N. lat. 51° 33′. E. long. 8° 11′.—Alſo, a river of Eaſt Frieſland, formed by the union of the Solte and Vehne, which, after a ſtraight courſe, runs into the Leer near Stikhuſen.

SOETA, in *Ancient Geography*, a town of Scythia, beyond the Imaus. Ptolemy.

SOETERWEER, in *Geography*, a town of Holland; 8 miles E. of the Hague.

SOFA, in the Eaſt, a kind of alcove raiſed half a foot above the floor of a chamber, or other apartment; and uſed as the place of ſtate, where viſitors of diſtinction are received.

Among the Turks, the whole floor of their ſtate-room is covered with a kind of tapeſtry, and on the window-ſide is raiſed a ſofa or ſopha, laid with a kind of matraſs, covered with a carpet much richer than the other. On this carpet the Turks are ſeated, both men and women, like the taylors in England, croſs-legged, leaning againſt the wall, which is bolſtered with velvet, ſattin, or other ſtuff, ſuitable to the ſeaſon. Here they eat their meals; only laying a ſkin over the carpet, to ſerve as a table-cloth, and a round wooden board over all, covered with plates, &c.

The ambaſſadors of France ſtood out a long while, and refuſed to viſit the grand vizir, unleſs he would receive them on the ſofa: at length he granted them the ſofa.

SOFALA, Zofala, or *Quiteve*, in *Geography*, a kingdom of Africa, bounded on the N. and W. by the ſtates of Mocaranga, on the E. by the Mozambique channel, and on the S. by Sabia, about 350 miles from E. to W. and 120 from N. to S., extending about 50 leagues along the coaſt and about 80 into the interior of the country. This country is ſaid to be ſubject to a Mahometan prince, tributary to the king of Portugal. Its capital, of the ſame name, was, at the arrival of the Portugueſe, an inconſiderable town, without walls, and fenced only with a thorny hedge; but it has ſince been fortified, and much improved, as well as the fort, which they conſtructed for its defence. It was then called "Cuama;" but geographers and pilots retain its ancient name of Sofala. It is conveniently ſituated on a ſmall iſland, at the mouth of the river Cuama. On the coaſt are alſo two other towns, *viz.* Haulema and Dardema, with ſeveral obſcure villages. The natives of Sofala are generally black, with ſhort curled hair; in ſhape taller and more genteel than the negroes of Mozambique, Quiloa, &c. Their common dreſs is a piece of ſilk or cotton, wrapped round the middle, covering them to the knees; the reſt of the body being naked, except the head, as perſons of the ſuperior claſs wear a kind of turban. All perſons adorn their necks, arms, wriſts, legs, and ancles, with rings of gold, ſilver, amber, or coloured beads, according to their condition. The ſtuffs and trinkets uſed in their dreſs are chiefly imported from Bombay by the Portugueſe; and thoſe of the better ſort affect to wear ſwords with handles of ivory. The inhabitants of the country and town of Sofala are a mixture of Mahometan Arabs, idolatrous Caffres, and Portugueſe Chriſtians. Thoſe who inhabit the coaſt ſpeak the Arabic tongue, which is their native language; as they are not the original natives but the deſcendants of the Arabs, who, leaving their native country, ſettled more or leſs on this coaſt. They cultivate rice and millet for bread, and eat the fleſh of elephants, large and ſmall cattle, and alſo fiſh, with great variety of which the ſea and rivers abound. They likewiſe make beer both of rice and millet, and ſome other liquors from honey, palm, and other fruits. Honey is abundant, and bees-wax ſerves them to exchange for painted cotton or ſilk, and other cloths. Their principal commerce is carried on with the inhabitants of Mozambique, Quiloa, Mombaça, and Melinda, who come hither in their "zambucks," or ſmall barges, which are freighted with a variety of the fore-mentioned cloths of all colours, exchanging them for gold, ivory, wax, or ambergris, and alſo with the Portugueſe. The Arabians exchange goods from the Eaſt Indies and the Red ſea, to the amount of 140,000*l.* ſterling annually for ivory and gold. Beſides the gold which is brought from Mocaranga, Sofala has ſome very conſiderable mines of that metal, which, according to the reports of the Portugueſe inhabitants, have yielded to the value of above two millions of merigals yearly, each merigal being valued at about fourteen French livres, amounting, according to Mr. Savary's ſtatement, to 1,166,666*l.* ſterling. The ſands alſo of the river Sofala contain a very conſiderable mixture of gold-duſt. Some perſons have even affirmed that Solomon obtained his gold, which is ſo highly commended by the ſacred hiſtorians, from this country, and that Sofala is the celebrated Ophir; the gold being allowed to be the pureſt and fineſt in all Africa. (See Ophir.) The Mahometan religion is ſaid by many writers to be that of the king and court, and of a great part of the people; but others think it more probable, that the original natives are wholly deſtitute of any religion; and that the Arabians, who have ſettled on this coaſt, are the only Mahometans, except ſome few proſelytes, from the Negroes, who became ſuch for the ſake of commerce; as they obſerve, that all the merchants who came hither from Quiloa, Mombaça, and Melinda, are of that religion. S. lat. 19° to 22°. E. long. 33° to 36°.

Sofala, a town of Africa, in the country of the ſame name. S. lat. 19° 22′. E. long. 36°. See the preceding article.—Alſo, a river of Africa, which riſes in the county of Mocaranga, and purſuing an eaſterly courſe, runs into the ſea, S. lat. 19° 22′.

SOFEE. See Sophi.

SOFFIETTA, in *Ichthyology*, the bellows-fiſh, a name by which ſome have called the ſcolopax, a ſmall ſea-fiſh, common in the markets of Rome and Venice.

SOFFINGERBA, in *Geography*, a town of Italy, in Friuli; 4 miles N.N.W. of Friuli.

SOFFITA, **Soffit**, or *Sofit*, in *Architecture*, any timber ceiling, formed of croſs-beams, or flying corniches; the ſquare compartiments or pannels of which are enriched with ſculpture, painting, or gilding.

The word is Italian, and ſignifies the ſame with the Latin *lacunar* and *laquear;* with this difference, that *lacunar* is uſed for any ceiling with ſquare, hollow pannels, called *lacus;* and *laquear* for compartiments interlaced with plat-bands, after the manner of knots or *laquei.*

Such are thoſe we ſee in the baſilics and palaces of Italy, in the apartments of Luxembourg, at Paris, &c.

Soffita, or *Soffit*, is alſo uſed for the under ſide or face of an architrave; and more particularly for that of the corona or larmier, which the ancients called *lacunar*, the French *plafond*, and we uſually the *drip*.

It is enriched with compartiments of roſes; and in the Doric order has eighteen drops, diſpoſed in three ranks, ſix in each, placed to the right of the guttæ, at the bottom of the triglyphs.

SOFI, or **Sophi.** See Sophi.

SOFIA, in *Geography.* See Sophia.

SOFIANA, a town of Perſia, in Adirbeitzan; 25 miles S.W. of Tabris.

SOFIT, or **Soffit**, the internal ſuperficies of an arch: ſometimes it ſignifies the opening itſelf.

SOFR, in *Geography*, a town of Arabia, in the province of Hedsjas; 70 miles S.E. of Mecca.

SOFRA, a town of Arabia, in the province of Nedsjed; 50 miles N.E. of Kariatain.

SOFREGAM, a town of the iſland of Ceylon; 54 miles S. of Candi.

SOFROI, a town of Fez, in the province of Chaus, trading principally in oil; 12 miles E. of Fez.

SOFT Chalk, in *Agriculture*, a ſort of foſſile marle, which readily moulders down and becomes blended with the mould of the ſoil, on which account it forms an excellent manure, free from the objection made to that of the hard kind, which moſtly requires to be reduced into lime. This ſort of ſubſtance is often met with at ſome depth at the bottoms of chalk hills, where ſearch ſhould be conſtantly made for it, as it may become of great value as manure. All ſoft mouldering chalks are not only excellent ſubſtances for applying on lands that are of the ſtiffiſh kinds, but they commonly form good ſoils, where they are the principal material.

Soft *Graſs*, a troubleſome ſort of graſs among moiſt arable lands in ſome places. See Holcus.

Soft *Meadow-Graſs*, the common name of a common graſs in moſt meadows, but which is of no great value for the purpoſes of the farmer. There is alſo a creeping ſoft graſs often met with, which is ſaid to be uſeful on dry ſandy ſoils in producing a turf or ſward. See Holcus.

Soft *Pulſe*, *Roe*, and *Soap*. See the ſubſtantives.

SOFTENING, in *Painting*, the mixing and diluting of colours with the bruſh or pencil.

To ſoften deſigns in black and white, made with the pen, &c. ſignifies to weaken the teint.

To ſoften a portrait, according to Felibien, is to change ſome of the ſtrokes, and give a greater degree of ſweetneſs and ſoftneſs to the air of it, which before had ſomething rough and harſh in it.

SOGANA, in *Ancient Geography*, a town of Judea, in the half tribe of Manaſſeh, on the other ſide of Jordan. It was fortified by Joſephus, when he was governor of Galilee.

SOGANLIK, in *Geography*, a town of European Turkey, in Bulgaria, on the Black ſea; 8 miles E. of Varna.

SOGD, the moſt celebrated and fertile diſtrict of Great Bucharia, being the ancient *Sogdiana*, which ſee. See Bucharia.—Alſo, a river which pervades this diſtrict, and which, at the diſtance of 100 miles from Samarcand, ſituated on its ſouthern bank, after waſhing the walls of Bokhara, paſſes through a conſiderable lake, and is ſuppoſed to join the Oxus or Amu.

SOGDI, in *Ancient Geography*, a people of India, on this ſide of the Ganges, according to Quintus Curtius, who places them on the left bank of the river Indus. The ſame hiſtorian informs us that Alexander built a city in the country of theſe people, and called it Alexandria. He alſo relates, that when ſome of theſe people, who reſided not far from the country of Odin's Goths, were condemned to death by Alexander on account of a revolt, they rejoiced greatly, and teſtified their joy by ſinging verſes and dancing. When the king inquired the reaſon of their joy, they anſwered, that "being ſoon to be reſtored to their anceſtors by ſo great a conqueror, they could not help celebrating ſo honourable a death, which was the wiſh of all brave men, in their own accuſtomed ſongs." This correſpondence of manners and principles between the Scandinavians and the Sogdians furniſhes a ſtriking proof of Odin's migration from the E. to the N.; firſt, in the ſpontaneous exerciſe of the poetical talent; and, ſecondly, in the opinion, that a glorious or warlike death, which admitted them to the company of their friends other, though there is conſiderable difference in this reſpect among different earthy matters, ſome being liable to ſuſtain a great number of different plants in a vigorous ſtate of growth, almoſt immediately after they become mixed with the ſoil, while others require to be applied and united for a length of time before they afford ſuſtenance to any kind of vegetable whatever, and even then only yield a ſcanty ſupply of nouriſhment, and that for the ſupport of a few particular ſorts of plants. Where the former ſorts of materials are abundant, the ſoils are generally fertile and productive; but where the latter prevail, they are moſtly ſterile and unfriendly to vegetation. Alſo that ſoils, beſides poſſeſſing the proper earthy matters, muſt be embued with other principles, ſuch as the aqueous and carbonaceous, and have ſuch a conſiſtence and texture as will properly ſupport the plants, as well as ſuch proportions of the ſeveral materials as will admit of their being retained, and applied in ſuch quantities as are ſuitable for the purpoſes of vegetation, according to the differences of climate in reſpect to moiſture, and the varieties of ſituation in regard to the lands, in order to be rich, fruitful, and productive, in the different kinds of vegetable crops. It has been ſtated likewiſe, that the bodies or materials, ſo far as they are yet known, that have a tendency to leſſen the fertility of ſoils, are the oxyds or calces of particular metals, ſome coaly and pyritical matters, acids, and certain heathy vegetable ſubſtances. But that ſome of theſe ſubſtances, though unfriendly to the growth of vegetables, when in theſe circumſtances, on being blended and united with other materials that enter into the compoſition of ſoils, operate upon them in ſuch a manner as to render them more fertile than they would have been without them. Mixtures and impregnations of this nature are conſtantly taking place in ſoils, which cannot be eaſily comprehended or aſcertained, but which produce great and important effects and changes in them. From this cauſe, ſoils which are apparently ſimilar in every reſpect, on being brought into cultivation, frequently turn out to be eſſentially different. And it is well known to moſt perſons converſant with practical agriculture, that ſoils in which calcareous matter is predominant, even when they are grown ſo poor and exhauſted as to be almoſt incapable of producing any of the other crops commonly cultivated on them, will bear large and repeated crops of one ſort of vegetable, that of ſaintfoin; and that other ſoils which are capable of affording the common crops in an abundant manner, cannot be made to produce this. In the ſame way, ſuch calcareous ſoils as have been cultivated for a great length of time, and are conſequently much impregnated with manure, afford plentiful crops of barley; while oat-crops, if attempted to be raiſed upon them in ſuch a ſituation, are weak, puny, and relatively extremely ſmall. And, on the contrary, ſome primitive ſoils, not originally containing any calcareous materials, and which, not having been cultivated, cannot be impregnated with manures on firſt being broken up, often yield aſtoniſhing crops of oats, while barley can ſcarcely be raiſed at all upon them. Theſe and many other ſimilar facts, noticed by cultivators of the ſoil, ſufficiently ſhew the effects which even trifling mixtures of certain matters have in altering their qualities, and rendering them more or leſs fertile, as well as more or leſs proper for the growth of particular ſorts of crops without there being any external appearance of ſuch alteration. Further, ſoils are alſo found to differ greatly from their depths, and the nature of the ſub-ſoils on which they reſt. It is ſtated as a fact well known by practical farmers, and which the experience of every day confirms, that even the ſoils that are conſtituted of the moſt ſuitable ſubſtances for the purpoſes of vegetation, when only a few inches in depth, and depoſited upon beds of cold wet clay, rock, or chalk, are by no means ſo fruitful and productive as thoſe which are thicker, though of inferior quality, but reſting on a bottom which is more dry and gravelly. The difference of weight and tenacity in the under ſtrata of ſoils, likewiſe introduces great variety in regard to their powers and capabilities of raiſing and rearing vegetable productions in the way of crops upon them.

The variations in the weights of ſoils are very material, as they ſhew in ſome meaſure the quantities of animal and vegetable matters with which they are impregnated in different caſes, the lighter ſorts being in moſt inſtances the moſt abundant in ſuch ſubſtances. The variations in their powers and properties of diſſipating or holding the moiſture which they contain are alſo very material and important, as they denote, in ſome degree, the nature of their compoſitions, and their utility for the growth of different ſorts of plants as crops.

The nature and variations of ſoils, in ſo far as they are more or leſs capable of imbibing and retaining the principles of heat, or more *cold* and raw, or *warm* in their qualities, which are by no means abſurdities or prejudices, as ſome have ſuppoſed, are highly deſerving of the attention of the philoſophical farmer, as ſome ſoils are evidently much more heated by the effects of the ſun than others, all other circumſtances being the ſame, while ſoils brought to the ſame ſtate of heat cool in different lengths of time, or ſome much faſter than others. This property, which has hitherto been but little attended to, is thought to be probably of conſiderable importance by the above writer on chemiſtry. It is conceived, that in general ſoils that conſiſt principally of a ſtiff white clay are difficultly heated; and that, being commonly very moiſt, they retain their heat only for a very ſhort time. Chalky ſoils are ſimilar in one particular, which is that of their being heated with difficulty; but being drier they retain their heat longer, leſs being ſuppoſed to be conſumed in producing the evaporation of their moiſture.

It has been found that a black ſoil, which contained much ſoft vegetable matter, was moſt heated by the ſun and air; and that the coloured ſoils, and thoſe containing a large proportion of carbonaceous or ferruginous matter, when expoſed under equal circumſtances to the ſun, acquire a much higher temperature than pale-coloured ſoils.

In all caſes, when ſoils are perfectly dry, thoſe that are the moſt readily heated by the power of the ſun, cool likewiſe in the moſt ready manner; but ſir Humphrey Davy has experimentally aſcertained, that the darkeſt coloured dry ſoil, or that which contains abundance of animal and vegetable matter; ſubſtances which moſt facilitate the diminution of temperature, when heated to the ſame extent, provided it be within the common limits of the effects of the ſun's heat, will cool more ſlowly than a wet pale ſoil, wholly compoſed of earthy matter. He found that a rich black mould, which contained nearly a fourth part of vegetable matter, had its temperature increaſed in the courſe of an hour from 65° to 88°, by expoſure to the ſun-ſhine; while a chalk ſoil was heated only to 69° under the ſame circumſtances and length of time. But the mould removed into the ſhade where the temperature was 62°, loſt, in half an hour, 15°; while the chalk, under the ſame circumſtances, had loſt only 4°. Farther, a brown fertile ſoil and a cold barren clay were each artificially heated to 88°, having been previouſly dried: they were then expoſed in a temperature of 57°; in half an hour the dark ſoil was found to have loſt 9° of heat; the clay had loſt only 6°. An equal portion of the clay containing moiſture, after being heated to 88°, was expoſed in a temperature of 55°; in leſs than a quarter of an hour it was found to have gained the temperature of the room. In all theſe trials the ſoils were put upon ſmall trays made of tin-plate two inches ſquare and half an inch in depth, the temperature being aſcertained by a thermometer of a very delicate kind.

It is upon the whole ſuppoſed, that nothing can be more evident, than that the genial heat of the ſoil, particularly in the ſpring ſeaſon, muſt be of the greateſt and moſt material uſe and importance to the raiſing plants as crops. And that when the leaves are fully and completely developed or ſpread out, the ground or land is conſiderably ſhaded; and any injurious influence or conſequence, which in the ſummer ſeaſon might have been apprehended from too great a heat, wholly prevented: ſo that the temperature of the ſurface, when bare and expoſed to the effects of the ſun, affords at leaſt, it is ſuppoſed, one indication of the ſtate of its fertility; and that the thermometer may therefore be, it is believed, ſometimes an uſeful inſtrument to the purchaſer as well as improver of lands.

The moiſture preſent in ſoils has likewiſe an effect and influence on their temperatures; and the particular manner or method in which it is diſtributed through, or combined with, the earthy, or perhaps other materials, is of great conſequence and importance, in ſo far as it relates to the nouriſhment of the plants which grow upon them. The above chemico-agricultural writer thinks, that where the water is too ſtrongly attracted by the earths, it will not be abſorbed by the roots of the plants; and that where it is in too great quantity, or too looſely united to them, it will tend to injure or deſtroy the fibrous parts of the roots. In his opinion there are two ſtates in which water ſeems to exiſt in the earths, and in animal and vegetable ſubſtances: in the firſt ſtate, it is conceived to be united by chemical, in the other by coheſive attraction. The former of theſe is illuſtrated by the pouring of pure ſolutions of ammonia or potaſſa into thoſe of alum, when the alumine or alumina falls down combined with water; and the dry powder affording, by diſtillation, more than half its weight of water. Alſo, by the moiſture which wood, muſcular fibre, and gum, that have been heated to 212°, afford in the ſame way at a red heat, which is likewiſe water held in the ſame manner.

The latter is ſhewn, it is ſuppoſed, when dried pipe-clay, at the temperature of the atmoſphere, is brought into contact with water, as the laſt is rapidly abſorbed. In general too, ſoils, as well as vegetable and animal ſubſtances that have been dried at a heat below that of boiling water, increaſe in weight by expoſure to the air, in conſequence of their abſorbing water from it, which is in the ſtate of vapour, on account of this ſort of attraction.

The water which is *chemically* combined among the principal component parts of ſoils, unleſs in the caſe of the decompoſition of animal or vegetable ſubſtances, cannot, it is ſuppoſed, be abſorbed by the roots of plants; but that which *adheres* to the parts of the ſoil is in conſtant uſe in vegetation. Indeed, it is believed that there are few earthy mixtures met with in ſoils that contain any chemically combined water; water is expelled from the earths by moſt ſubſtances that combine with them. As for inſtance, when a combination of lime and water is expoſed to carbonic acid, that fluid ſubſtance takes the place of the water; and compounds of alumina and ſilica, or others of the earths, do not chemically unite with water; and ſoils, as has been ſeen, are formed either by earthy carbonates, or compounds of pure earths and metallic oxyds.

However, when ſaline ſubſtances exiſt in ſoils, they may, it is ſaid, be united to water, both chemically and mechanically; but they are always, it is ſuppoſed, in too ſmall a proportion to materially influence the relations of the ſoils to water.

The power or capability of the ſoil to abſorb and receive water, in conſequence of this ſort of attraction, depends greatly upon the ſtate of diviſion of its parts; as the finer and more minute this is, the greater and more powerful is the capacity for abſorption. The different conſtituent parts of ſoils ſeem likewiſe to operate, even by this kind of attraction, with different degrees of force and energy. In this way vegetable ſubſtances ſeem, it is ſaid, to be more abſorbent than animal ſubſtances; animal ſubſtances more ſo than compounds of alumina and ſilica; and compounds of alumina and ſilica more abſorbent than carbonates of lime and magneſia. Theſe differences may, however, it is ſuggeſted, poſſibly depend upon the differences in their ſtates of diviſion, and on the ſurface which is expoſed.

This power or capability of ſoils to abſorb water from the air is, it is ſuppoſed, much connected with fertility. The ſoils which are the moſt efficient in ſupplying plants with water, by means of atmoſpheric abſorption, are, it is ſaid, thoſe in which there is a due and proper mixture of ſand, finely divided clay, and carbonate of lime, with ſome animal and vegetable matter; and which are ſo looſe and light as to be freely and readily permeable to the atmoſphere. In ſo far as regards this quality, carbonate of lime, and animal and vegetable matter, are, it is ſaid, of great uſe in ſoils. They give abſorbent power to them, without at the ſame time giving tenacity: ſand, too, conſtantly deſtroys tenacity, but, on the contrary, affords little power of abſorption. The above writer has compared the abſorbent powers of many ſoils, in ſo far as it relates to atmoſpheric moiſture, and has conſtantly found it to be the greateſt in the moſt fertile of them; ſo that it is ſuppoſed to afford one mode of judging of the productiveneſs of land.

Thus, the water, and the decompoſing animal and vegetable matter exiſting in the ſoil, conſtitute, it is ſuppoſed, the true nouriſhment of plants; and that as the earthy parts of the ſoil are uſeful in retaining water, ſo as to ſupply it in the proper proportions to the roots of the vegetables, ſo they are likewiſe efficacious in producing the proper diſtribution of the animal or vegetable matter. When equally blended and intermixed with it, they alſo prevent it from decompoſing in too rapid a manner; and by their means the ſoluble parts are ſupplied in proper proportions or quantities. But beſides this agency, which may be conſidered as mechanical, the writer conceives that there is another, between ſoils and organizable matters, which may be regarded as chemical in its nature. The earths, and even the earthy carbonates, have, it is ſaid, a certain degree of chemical attraction for many of the principles of vegetable and animal ſubſtances, as is readily exemplified in the caſe of alumina and oil: for when an acid ſolution of alumina is mixed with a ſolution of ſoap, which conſiſts of oily matter and potaſſa, the oil and the alumina will unite and form a white powder, which will ſink to the bottom of the fluid which holds it. The extract, too, from decompoſing vegetable matter, when boiled with pipe-clay or chalk, forms, it is ſaid, a combination by which the vegetable matter is rendered more difficult of decompoſition and ſolution. Pure ſilica and ſiliceous ſands have, it is remarked, little action of this kind; and the ſoils which contain the moſt alumina and carbonate of lime, are thoſe which act with the greateſt chemical energy in preſerving manures. Such ſoils are ſuppoſed to deſerve the appellation which is commonly given to them, of rich ſoils; as the vegetable nouriſhment is long preſerved in them, unleſs when taken up by the organs of plants. Siliceous ſands, on the contrary, are thought to merit the term hungry, which is commonly applied to them; as the vegetable and animal matter they contain, not being attracted by the earthy conſtituent parts of the ſoil, are more liable to be decompoſed by the action of the atmoſphere, or carried off or away from them by water in different ways. In moſt of the black and brown rich vegetable moulds, the earths ſeem, it is ſuppoſed, to be in combination with a peculiar extractive matter, afforded during the decompoſition of vegetables. This is ſlowly taken up, or attracted, it is believed, from the earths by water, and appears to conſtitute a prime cauſe of the fertility of the ſoil. The ſtandard of fertility of ſoils for different plants muſt vary, it is ſuppoſed, with the climate, and muſt be particularly influenced by the quantity of rain. The power of ſoils to abſorb moiſture ought, it is ſaid, to be much greater in warm or dry counties than in cold and moiſt ones, and the quantity of clay or vegetable or animal matter they contain greater. Such ſoils as are on declivities, alſo, ſhould be more abſorbent than thoſe on plains, or in the bottoms of vallies. Their productiveneſs is likewiſe influenced by the nature of the ſub-ſoil, or the ſtratum on which they reſt. When ſoils are immediately ſituated upon a bed of rock or ſtone, they are much ſooner, it is ſaid, rendered dry by evaporation, than when the ſub-ſoil is of clay or marle; and a principal cauſe of the great fertility of the land in the moiſt climate of Ireland is, it is imagined, the proximity of the rocky ſtrata to the ſoil. A clayey ſub-ſoil will ſometimes, it is thought, be of material advantage to a ſandy ſoil; and in this caſe it will retain moiſture, in ſuch a manner as to be capable of ſupplying that loſt by the earth above, in conſequence of evaporation, or the conſumption of it by plants as crops. A ſandy or gravelly ſub-ſoil often corrects the imperfections of too great a degree of abſorbent power in the true ſoil. In calcareous countries, where the ſurface is a kind of marle, the ſoil is often found, it is obſerved, only a few inches above the limeſtone, yet its fertility continues unimpaired by the proximity of the rock; though in a leſs abſorbent ſoil, this ſituation would occaſion barrenneſs; and thus the ſandſtone and limeſtone hilly ſoils, in ſome weſtern diſtricts, may be readily diſtinguiſhed at a diſtance, in the ſummer ſeaſon, by the different tints or caſts of colour in the vegetation. On the ſandſtone kind it will commonly appear brown and burnt up; while on the limeſtone ſort, it will be green and flouriſhing in a conſiderable degree.

It not unfrequently happens that ſoils are met with in a quite unaltered ſtate, upon the rocks from which they were produced. The manner in which they were formed may eaſily be conceived, it is ſuppoſed by ſir Humphrey Davy, by referring to the caſe of *ſoft* or *porcelain granite*, which conſiſts of three ingredients, quartz, felſpar, and mica. The quartz he conſiders as almoſt pure ſiliceous earth, in a cryſtalline form. The felſpar and mica are very compounded ſubſtances: both contain ſilica, alumina, and oxyd of iron; in the former there is commonly lime and potaſſa; in the latter, lime and magneſia. Therefore, when a granite rock of this ſort has been long expoſed to the influence of air and water, he ſuppoſes the lime and potaſſa, contained in its conſtituent parts, are acted upon by water or carbonic acid; and the oxyd of iron, which is moſtly in the leaſt oxyded ſtate, tends to combine with more oxygen; in conſequence of which the felſpar decompoſes, as well as the mica, but the firſt in the moſt rapid manner. The felſpar, which is as it were the cement of the ſtone, forms a fine clay; the partially decompoſed mica blends and intermixes with it as ſand; and the undecompoſed quartz appears as gravel, or ſand of different degrees of fineneſs. On the ſmalleſt layer of earth being formed on the ſurface of the rock, the ſeeds of moſſes, and other imperfect plants, which are moſtly floating in the ſurrounding atmoſphere, and which have made it their reſting place, begin, it is ſaid, to vegetate; and their decay, death, and decompoſition afterwards, afford a certain quantity of organizable matter, which mixes with the earthy materials of the rock. In this improved ſoil, more perfect plants are capable of ſubſiſting: theſe, in their turn, abſorb nouriſhment from the water of the atmoſphere; and, after periſhing, afford new materials to thoſe already provided. The decompoſition of the rock ſtill continues; and at length, by ſuch ſlow and gradual proceſſes, a ſoil is formed, in which even foreſt trees can, it is ſuppoſed, fix their roots, and which is fitted to reward the labours of thoſe undertaking its cultivation.

It is likewiſe noticed, that where ſucceſſive generations of vegetables have grown upon a ſoil, unleſs part of their produce has been carried away by man, or conſumed by animals, the vegetable matter increaſes in ſuch proportion, that the ſoil approaches to a peat in its nature; and if it be ſo placed as that it becomes impregnated with water from a higher ſituation, it gets ſpongy, and is gradually rendered incapable of ſupporting better plants. A great number of peat moſſes appear, however, it is ſaid, to have been formed by the deſtruction of foreſts, by the imprudent uſe of the hatchet, at ſome early former period. It is ſuppoſed, that when the trees in the outer parts of the woods were cut down, thoſe in the interior were expoſed to the influence of the winds; and, having been accuſtomed to ſhelter, became unhealthy, and died in their new ſituations; the leaves and branches of which, gradually decompoſing, produced a ſtratum of vegetable matter. In ſeveral of the great peat bogs in the north of this and the neighbouring country, the larger trees met with on the outer parts of them, it is ſaid, bear the marks of having been felled; while in the interior, few entire trees are found: and the cauſe is, probably, it is ſuppoſed, that they fell by gradual decay; and that the fermentation and decompoſition of the vegetable matter were moſt rapid, where it was in the greateſt quantity or proportion.

Other leſs healthy ſorts of ſpurious peat bogs are formed in watery ſituations, by the accumulation of the remains of aquatic plants. There is here a fermentation of an apparently different kind, and a much greater evolution of gaſeous matter.

It is found that the earthy matter of peats is invariably analogous to that of the ſtratum on which they repoſe: the plants which have formed them muſt have derived the earths that they contained from this ſtratum. Thus, the above writer obſerves, that in the counties of Wilts and Berks, where the ſtratum below the peat is chalk, calcareous earth abounds in the aſhes, and very little alumina and ſilica. They likewiſe contain much oxyd of iron and gypſum, both of which may be derived from the decompoſition of pyrites, which is ſo abundant in chalk. The different ſpecimens of peat that have been burnt by this experimenter, from the granitic and ſchiſtoſe ſoils of different parts of theſe iſlands, have conſtantly given him aſhes principally of a ſiliceous and aluminous nature; but one from the county of Antrim, in Ireland, yielded aſhes, which afforded very nearly the ſame conſtituent parts as the great baſaltic ſtratum of the county.

It is ſuggeſted that poor and hungry ſoils, ſuch as are produced from the decompoſition of granitic and ſandſtone rocks, remain very often for ages with only a thin covering of vegetation; but that ſoils from the decompoſition of limeſtone, chalk, and baſaltes, are not unfrequently clothed by nature with the perennial graſſes, and afford, when ploughed up, a rich bed of vegetation for every ſort of cultivated plants.

From what has been ſaid on the formation of rocky ſoils, it muſt be obvious that they are as various as the rocky matters from which they are produced, and probably much more ſo, in conſequence of the alterations which have taken place in them, from the continued operation of water, and different other cauſes.

In ſo far as the cropping of land is concerned, it muſt be evident that no general principle can be laid down for it, unleſs the whole of the circumſtances connected with the nature, compoſition, and ſituation of the ſoils, as well as ſubſoils, be fully underſtood.

In like manner, in the above writer's opinion, the modes of cultivation in different ſoils muſt be different; as the ſame practice that may be excellent in one caſe may be deſtructive in others. Thus, for inſtance, deep ploughing may be very advantageous and profitable in rich thick ſoils; but in fertile ſhallow ones, upon cold clay or ſandy ſub-ſoils, very injurious and hurtful. Siliceous ſandy ſoils are much more productive in moiſt wet climates, where the fall of rain is great, ſuch as thoſe in the ſouth-weſt and north-weſt of this country, and in ſome places in Ireland, than in dry diſtricts; and in ſuch ſituations, wheat and beans will require leſs coherent and abſorbent ſoils than in thoſe which are drier; and bulbous-rooted plants will, it is ſaid, thrive well in ſoils that have as many as fourteen parts out of fifteen of ſand. The exhauſting powers of crops, too, it is aſſerted, will be influenced by the ſame circumſtances; as where ſufficient moiſture cannot be abſorbed by plants, they muſt neceſſarily take up more manure. In the ſouth-weſtern and north-weſtern parts of this iſland, as well as in Ireland, corn will, it is ſaid, exhauſt leſs than in dry inland diſtricts; and oats are much more deteriorating, eſpecially in dry climates, than in ſuch as are moiſt. In many other inſtances, the ſame is likewiſe the caſe.

In regard to the conſtitution or compoſition of fertile ſoils, the firſt eſſential requiſite, according to Mr. Kirwan, is, that it contain a ſufficient quantity of the three or four ſimple earths above mentioned, and of the ſoluble carbonaceous principle; and that the other requiſites are, that the proportion of each, and the general texture of the ſoil, be ſuch as to enable it to admit and retain as much water as is neceſſary to vegetation, and no more. Alſo, further, that as it has been ſeen that the retentive powers of moiſture are very different in the ſimple earths, the proportions in which the fertility of a ſoil requires them to be mixed muſt be different in climates and countries that differ conſiderably in moiſture; in the *drier*, they muſt be ſuch as are moſt retentive; in the *moiſter*, ſuch as ſuffer it to paſs or evaporate more eaſily. The ſame remark alſo extends to ſituation. Lands on a plain ſhould be ſo conſtituted, as to be leſs retentive of water than thoſe ſituated on a declivity; as has been ſeen, and is very evident: conſequently, lands that have a retentive or impermeable ſub-ſoil, ſhould be differently conſtituted from thoſe that have one leſs retentive, or more permeable. And the time of the year in which rain moſt abundantly falls may alſo be worthy of notice, in adjuſting this buſineſs.

From a variety of facts and obſervations, which we cannot minutely detail, it is inferred that in the drier countries, where the fall of rain is but 20 inches, the ſoil, to be fertile, muſt be cloſer, and the quantity of calcareous earth much increaſed, and that of the ſiliceous earth much diminiſhed. Thus, in the climate of Turin, where the fall of rain exceeds 40 inches, the proportion of ſiliceous earth is from 77 to 80 *per* cwt., and that of calcareous from 9 to 14, to ſuffer this exceſs of rain more eaſily to evaporate. In the climate of Upſal, where the fall of rain is 24 inches, the proportion of ſilex is only 56 *per* cwt., but that of calx is 30; and in the climate of Paris, which is ſtill drier, the proportion of ſilex is only from 46 to 51, and that of calx 37.5 *per* cwt. And hence we may perceive the neceſſity of attending to the average quantity of rain, to judge of the proper conſtitution of fertile lands upon fixed principles. The quantity of rain differs much, in different parts of the ſame kingdom; but in general, in Ireland, Mr. Kirwan believes it to be between 24 and 28 inches, on an average. In the two laſt mixtures, the proportions vary conſiderably: the firſt may ſerve, it is ſaid, as a model for the heavier ſoils; and the ſecond for the lighter. In the following experiments, the carbonic principle ſeems to have been extracted from the ſurrounding garden-mould, with which the pots communicated, by means of their perforation at the bottom.

The author of a late work on "Agricultural Chemiſtry" ſtates, that as plants have no locomotive powers, they can only grow in places where they are ſupplied with food; and that the ſoil is neceſſary to their exiſtence, both as affording them properly the means of nouriſhment, and enabling them to fix themſelves in ſuch a manner as to obey thoſe mechanical laws, by which their radicles are kept below the ſurface, and their leaves expoſed to the free atmoſphere. That as the ſyſtems of roots, branches, and leaves, are very different in different vegetables, ſo they flouriſh moſt perfectly in different ſoils ſuited to them: the plants that have bulbous roots require a looſer and a lighter ſoil than ſuch as have fibrous roots; and the plants having only ſhort fibrous radicles ſtand in need of a firmer ſoil than ſuch as have tap-roots, or extenſive roots of the lateral kind.

He found a good turnip ſoil from Holkham, in the county of Norfolk, to afford eight out of nine parts ſiliceous ſand; and the finely divided matter to conſiſt of

Carbonate of lime - - - - -	63
Silica - - - - - - -	15
Alumina - - - - - - -	11
Oxyd of iron - - - - - -	3
Vegetable and ſaline matter - -	5
Moiſture - - - - - - -	3

A ſoil particularly fitted for raiſing flouriſhing oaks, to be conſtituted nearly as noticed afterwards, below.

An excellent wheat-ſoil from near Weſt Drayton, in the county of Middleſex, gave three parts in five of ſiliceous ſand; and the finely divided matter conſiſted of

Carbonate of lime - - - - -	28
Silica - - - - - - -	32
Alumina - - - - - - -	29
Animal or vegetable matter and moiſture	11

It is noticed, that of theſe ſoils, the firſt was the leaſt coherent in texture, and the laſt by far the moſt ſo. In all caſes, the conſtituent parts of the ſoil which give tenacity and coherence are, it is ſaid, the finely divided matters; and that they poſſeſs the power of giving thoſe qualities in the higheſt degree, when they contain much alumina. A ſmall quantity of finely divided matter is ſufficient, it is ſaid, to fit a ſoil for the production of turnips and barley; and the writer has ſeen a tolerable crop of turnips on a ſoil containing eleven parts out of twelve ſand. Any much greater proportion of ſand, however, it is ſtated, always produces abſolute ſterility. The ſoil of Bagſhot-Heath, which is wholly devoid of vegetable covering, contains, it is ſaid, leſs than one-twentieth of finely divided matter; 400 parts of it, which had been heated red, afforded the above writer 380 parts of coarſe ſiliceous ſand, 9 parts of fine ſand of the ſame kind, and 11 parts of impalpable matter, which was a mixture of ferruginous clay, with carbonate of lime. Vegetable or animal matters, when finely divided, not only give, it is ſaid, coherence, but likewiſe ſoftneſs and penetrability; but neither they, nor any other part of the ſoil, muſt be in too great proportion; and a ſoil is unproductive, if it conſiſts entirely of impalpable matter. Pure alumina or ſilica, pure carbonate of magneſia, are incapable of ſupporting healthy vegetation. And no ſoil is fertile, it is ſtated, that contains ſo much as nineteen parts out of twenty of any of the conſtituent materials that have been mentioned above.

In anſwer to the important queſtion, whether the pure earths in the ſoil only act in a mere mechanical manner, or as indirect chemical agents, or actually furniſh the food of the plants? it is ſtated, that as their baſes have not yet been decompoſed, there is no reaſon to ſuppoſe that they are capable of being converted into the elements of organized compounds, as into carbon, hydrogen, and azote. Plants have been made to grow, it is ſaid, in given quantities of earth, but they conſume very ſmall portions only; and what is loſt may be accounted for, by the quantities found in their aſhes, that is to ſay, it has not been converted into any new products. The carbonic acid united to lime or magneſia, if any ſtronger acid happens to be formed in the ſoil during the fermentation of vegetable matter, which will diſengage it from the earths, may, it is ſaid, be decompoſed; but the earths themſelves cannot be ſuppoſed convertible into other ſubſtances, by any proceſs taking place in the ſoil or land. In all caſes, the aſhes of plants, it is obſerved, contain ſome of the earths of the ſoil in which they grow; but theſe never equal more than one-fiftieth of the weight of the plant which is conſumed. On the whole, it is concluded, that if they be conſidered as neceſſary to the vegetable, it is as giving hardneſs and firmneſs to its organization. Thus wheat, oats, and many of the hollow graſſes, have, it is ſaid, an epidermis principally of ſiliceous earth; the uſe of which ſeems to be to ſtrengthen them, and defend them from the attacks of inſects and paraſitical plants.

It is ſtated that, for the moſt part, the ſoils, the conſtituent materials of which are the moſt various and contrary to each other, are thoſe of the alluvial kind, or which have been formed in a gradual manner from the depoſitions of rivers, or other waters: they are, in many caſes, extremely fertile. The writer juſt mentioned has examined ſome productive ſoils of this ſort, which have been very different in their compoſition. A very productive ſoil from the banks of the river Parrot, in the county of Somerſet, afforded eight parts of finely divided earthy matter, and one part of ſiliceous ſand: the analyſis of the former gave theſe reſults:

360 parts of carbonate of lime,
25 parts of alumina,
20 parts of ſilica,
8 parts of oxyd of iron,
19 parts of vegetable, animal, and ſaline matter.

A rich ſoil of this nature from near the Avon river, in the valley of Eveſham, in the county of Worceſter, gave three-fifths of fine ſand, and two-fifths of impalpable matter: the latter conſiſted of

35 Alumina,
41 Silica,
14 Carbonate of lime,
3 Oxyd of iron,
7 Vegetable, animal, and ſaline matter.

From a ſpecimen of good ſoil of Tiviotdale, five-ſixths of fine ſiliceous ſand, and one-ſixth of impalpable matter, were afforded: the latter conſiſted of

41 Alumina,
42 Silica,
4 Carbonate of lime,
5 Oxyd of iron,
8 Vegetable, animal, and ſaline matter.

And a ſoil affording excellent paſture from the valley of the Avon, near the town of Saliſbury, gave one-eleventh of coarſe ſiliceous ſand; the finely divided matter of which conſiſted of

7 Alumina,
14 Silica,
63 Carbonate of lime,
2 Oxyd of iron,
14 Vegetable, animal, and ſaline matter.

It is ſtated that, in all theſe caſes, the fertility ſeemed to depend upon the ſtate of diviſion and mixture of the earthy materials and the vegetable and animal matters; which may be readily explained from what has been already advanced.

And profeſſor Davy, in ſpeaking of the improvement of ſoils, as connected with the principle of their compoſition, remarks in the paper noticed above, that when a barren ſoil is examined with a view to its improvement, it ought, in all caſes, if poſſible, to be compared with an extremely fertile ſoil in the ſame neighbourhood, and in a ſimilar ſituation: the difference given by their analyſes would indicate the methods of cultivation; and thus the plan of improvement would be founded upon accurate ſcientific principles. And that, if the fertile ſoil contained a large quantity of ſand, in proportion to the barren ſoil, the proceſs of amelioration would depend ſimply upon a ſupply of this ſubſtance; and the method would be equally ſimple with regard to ſoils deficient in clay or calcareous matter. But that in the application of clay, ſand, loam, marle, or chalk to lands, there are no particular chemical principles to be obſerved; but when quicklime is uſed, great care muſt be taken that it is not obtained from the magneſian limeſtone; for in this caſe, as has been ſhewn by Mr. Tennant, it is exceedingly injurious to land. The magneſian limeſtone may be diſtinguiſhed from the common limeſtone by its greater hardneſs, and by the length of time that it requires for its ſolution in acids, and it may be analyſed by the proceſs for carbonate of lime and magneſia. When the analytical compariſon indicates an exceſs of vegetable matter as the cauſe of ſterility, it may be deſtroyed by much pulverization, and expoſure to air, by paring and burning, or the agency of lately made quicklime. And the defect of animal and vegetable matter muſt be ſupplied by animal or vegetable manure.

And it is further ſtated, that ſterile ſoils in different climates and ſituations muſt differ in compoſition. The general indications of fertility and barrenneſs, as found by chemical experiments, muſt neceſſarily differ in different climates, and under different circumſtances. The power of ſoils to abſorb moiſture, a principle eſſential to their productiveneſs,

ductiveneſs, ought, as has been ſeen, to be much greater in warm and dry countries, than in cold and moiſt ones; and the quantity of fine aluminous earth they contain larger. Soils, likewiſe, as already ſeen, that are ſituated on declivities, ought to be more abſorbent than thoſe in the ſame climate, on plains or in vallies. The productiveneſs of ſoils muſt likewiſe be influenced by the nature of the ſub-ſoil, or the earthy or ſtony ſtrata on which they reſt; and this circumſtance ought to be particularly attended to in conſidering their chemical nature, and the ſyſtem of improvement. Thus, a ſandy ſoil may ſometimes owe its fertility to the power of the ſub-ſoil to retain water; and an abſorbent clayey ſoil may occaſionally be prevented from being barren, in a moiſt climate, by the influence of a ſub-ſtratum of ſand or gravel. In regard to the chemical compoſition of fertile corn-ſoils in this climate, thoſe ſoils that are moſt productive of corn, contain always certain proportions of aluminous and calcareous earth, in a finely divided ſtate, and a certain quantity of vegetable or animal matter. The quantity of calcareous earth is however very various, and in ſome caſes exceedingly ſmall. A very fertile corn-ſoil from Ormiſton, in Eaſt Lothian, afforded the writer, in an hundred parts, only eleven parts of mild calcareous earth; it contained twenty-five parts of ſiliceous ſand; the finely divided clay amounted to forty-five parts. It loſt nine in decompoſed animal and vegetable matter, and four in water; and afforded indications of a ſmall quantity of phoſphate of lime. This ſoil was of a very fine texture, and contained very few ſtones or vegetable fibres. It is not unlikely that its fertility was in ſome meaſure connected with the phoſphate; for this ſubſtance is found in wheat, oats, and barley, and may be a part of their food. A ſoil from the low lands of Somerſetſhire, celebrated for producing excellent crops of wheat and beans without manure, he found to conſiſt of one-ninth of ſand, chiefly ſiliceous, and eight-ninths of calcareous marle tinged with iron, and containing about five parts in the hundred of vegetable matter. He could not detect in it any phoſphate or ſulphate of lime, ſo that its fertility muſt have depended principally upon its power of attracting principles of vegetable nouriſhment from water and the atmoſphere. And Mr. Tillet found that a ſoil compoſed of three-eighths of clay, two-eighths of river-ſand, and three-eighths of the parings of limeſtone, was very proper for wheat.

With reſpect to the compoſition of ſoils proper for bulbous roots and for trees, it is obſerved that, in general, bulbous roots require a ſoil much more ſandy, and leſs abſorbent, than the graſſes. A very good potatoe ſoil, from Varſel, in Cornwall, afforded him ſeven-eighths of ſiliceous ſand; and its abſorbent power was ſo ſmall, that one hundred parts loſt only two by drying at 400° Fahrenheit. Plants and trees, the roots of which are fibrous and hard, and capable of penetrating deep into the earth, will vegetate to advantage in almoſt all common ſoils which are moderately dry, and which do not contain a very great exceſs of vegetable matter. He found the ſoil taken from a field at Sheffield-Place, in Suſſex, remarkable for producing flouriſhing oats, to conſiſt of ſix parts of ſand, and one part of clay and finely divided matter. And one hundred parts of the entire ſoil ſubmitted to analyſis, produced

Subſtances.	Parts.
Water	3
Silex	54
Alumine	28
Carbonate of lime	3
Oxyd of iron	5
Decompoſing vegetable matter	4
Loſs	3

And on the advantages of improvements made by changing the compoſition of the earthy parts of ſoils, it is obſerved that, from the great difference of the cauſes that influence the productiveneſs of lands, it is obvious that, in the preſent ſtate of ſcience, no certain ſyſtem can be deviſed for their improvement, independent of experiment: but there are few caſes in which the labour of analytic trials will not be amply repaid by the certainty with which they denote the beſt methods of amelioration; and this will particularly happen, when the defect of compoſition is found in the proportions of the primitive earths. In ſupplying animal or vegetable manure, a temporary food only is provided for plants, which is in all caſes exhauſted by means of a certain number of crops; but when a ſoil is rendered of the beſt poſſible conſtitution and texture, with regard to its earthy parts, its fertility may be conſidered as permanently eſtabliſhed. It becomes capable of attracting a very large proportion of vegetable nouriſhment from the atmoſphere, and of producing its crops with comparatively little labour and expence.

There are different other caſes in which improvements may be directed in this way; as where the ſalts of iron or ſome acid material is found to prevail in ſoils, they may be altered and corrected by the uſe of lime in its moſt active ſtate. In this manner very ſterile ſoils, not deficient in texture, have been effectually improved. When the quantity of calcareous matter is too great, ſand or clay is the obvious remedy. If there be a deficiency of vegetable materials in light ſandy or gravelly ſoils, they may be permanently improved by the uſe of peat earth upon them. The peat-boggy and marſhy ſorts of ſoils, after proper draining, are moſtly made productive, by laying upon them ſandy, or ſtiff earthy matters in due proportion, eſpecially when the former are of the black ſoft peaty quality. In caſes where peaty ſoils are acid, or much impregnated with ferruginous ſaline matters, the uſe of calcareous ſubſtances is eſſentially neceſſary for bringing them into proper order.

It is conceived that the beſt natural ſoils are thoſe, the materials of which have been produced from ſtrata of different kinds, which have been the moſt perfectly divided in their parts by the operation of air and water, and are the moſt intimately blended and incorporated together. In improving ſoils artificially, it is in ſhort ſuppoſed, that the farmer cannot do better than imitate the proceſſes of nature. The materials ſuitable for the purpoſe are, it is ſaid, ſeldom far diſtant: coarſe ſand is often found immediately upon chalk; and beds of ſand and gravel are commonly below clay.

The labour of amending and improving the texture and conſtitution of ſoils, is repaid, it is ſaid, by many great permanent benefits; a ſmaller quantity of manure is required, and their fertility rendered ſecure, &c.

In order to aſcertain the properties and qualities of land, the method of chemical analyſis has been adopted. In this caſe the following rules and directions, laid down by profeſſor Davy in the paper befor alluded to, may be found uſeful in guiding the inquirer. All the varieties of ſoils may be analyſed in this way.

1. *Inſtruments required for the Analyſis of Soils.*—The really important inſtruments required for the analyſis of ſoils are, in his opinion, few, and but little expenſive. They are, a balance capable of containing a quarter of a pound of common ſoil, and capable of turning, when loaded, with a grain; a ſeries or ſet of weights, from a quarter of a pound troy to a grain; a wire ſieve, ſufficiently coarſe to admit a pepper-corn through its apertures; an Argand lamp and

ſtand ; ſome glaſs-bottles ; Heſſian crucibles ; porcelain or queen's ware evaporating baſons ; a Wedgewood peſtle and mortar ; ſome filters made of half a ſheet of blotting-paper, folded ſo as to contain a pint of liquid, and greaſed at the edges ; a bone-knife, and an apparatus for collecting and meaſuring aeriform fluids. And the chemical ſubſtances or re-agents required for ſeparating the conſtituent parts of the ſoil are, muriatic acid (ſpirit of ſalt), ſulphuric acid, pure volatile alkali diſſolved in water, ſolution of pruſſiat of potaſh and iron, ſuccinate of ammonia, ſoap-ley, ſolutions of carbonate of ammonia, of muriate of ammonia, ſolution of neutral carbonate of potaſh, and nitrate of ammonia. An account of the nature of theſe bodies and their effects may be found in Dr. Thomſon's Syſtem of Chemiſtry, and Henry's Epitome ; and the re-agents are ſold together with the inſtruments mentioned above, by Mr. Knight, Foſter-lane, Cheapſide, arranged in an appropriate cheſt.

2. *Mode of collecting Soils for Analyſis.*—In caſes where the general nature of the ſoil of a field is to be aſcertained, ſpecimens of it ſhould be taken from different places, two or three inches below the ſurface, and examined as to the ſimilarity of their properties. It ſometimes happens, that upon plains, the whole of the upper ſtratum of the land is of the ſame kind, and in this caſe one analyſis will be ſufficient ; but in vallies, and near the beds of rivers, there are very great differences, and it now and then occurs that one part of a field is calcareous, and another part ſiliceous ; and in this caſe, and in analogous caſes, the portions different from each other ſhould be ſeparately ſubmitted to experiment. Soils, when collected, if they cannot be immediately examined, ſhould be preſerved in phials quite filled with them, and cloſed with ground-glaſs ſtoppers. The quantity of ſoil moſt convenient for a perfect analyſis, is from two to four hundred grains. It ſhould be collected in dry weather, and expoſed to the atmoſphere till it becomes dry to the touch. The ſpecific gravity of a ſoil, or the relation of its weight to that of water, may be aſcertained by introducing into a phial, which will contain a known quantity of water, equal volumes of water and of ſoil, and this may be eaſily done by pouring in water till it is half full, and then adding the ſoil till the fluid riſes to the mouth ; the difference between the weight of the ſoil and that of the water will give the reſult. Thus, if the bottle contains 400 grains of water, and gains 200 grains when half filled with water and half with ſoil, the ſpecific gravity of the ſoil will be 2 ; that is, it will be twice as heavy as water : and if it gained 165 grains, its ſpecific gravity would be 1825, water being 1000. It is of importance that the ſpecific gravity of a ſoil ſhould be known, as it affords an indication of the quantity of animal and vegetable matter it contains ; theſe ſubſtances being always moſt abundant in the lighter ſoils. The other phyſical properties of ſoils ſhould likewiſe be examined before the analyſis is made, as they denote, to a certain extent, their compoſition, and ſerve as guides in directing the experiments. Thus, ſiliceous ſoils are generally rough to the touch, and ſcratch glaſs when rubbed upon it ; ferruginous ſoils are of a red or yellow colour ; aluminous ſoils adhere ſtrongly to the tongue, and emit a ſtrong earthy ſmell when breathed on ; and calcareous ſoils are ſoft, and much leſs adheſive than aluminous ſoils.

3. *Mode of aſcertaining the Quantity of Water of Abſorption in Soils.*—Soils, though as dry as they can be made by continued expoſure to air, in all caſes ſtill contain a conſiderable quantity of water, which adheres with great obſtinacy to the earths and animal and vegetable matter, and can only be driven off from them by a conſiderable degree of heat. The firſt proceſs of analyſis is, to free the given weight of ſoil from as much of this water as poſſible, without, in other reſpects, affecting its compoſition ; and this may be done by heating it for ten or twelve minutes over an Argand's lamp, in a baſon of porcelain, to a temperature equal to 300° Fahrenheit. In ſeveral experiments, in which this proceſs has been carried on by diſtillation, he has found the water that came over pure, and no ſenſible quantity of other volatile matter was produced. And in caſe a thermometer is not uſed, the proper degree may be eaſily aſcertained, by keeping a piece of wood in contact with the bottom of the diſh ; as long as the colour of the wood remains unaltered, the heat is not too high ; but when the wood begins to be charred, the proceſs muſt be ſtopped. A ſmall quantity of water will perhaps remain in the ſoil, even after this operation, but it always affords uſeful comparative reſults ; and if a higher temperature were employed, the vegetable or animal matter would undergo decompoſition, and in conſequence the experiment be wholly unſatisfactory. The loſs of weight in the proceſs ſhould be carefully noted, and when in four hundred grains of ſoil it reaches as high as fifty, the ſoil may be conſidered as in the greateſt degree abſorbent, and retentive of water, and will generally be found to contain a large proportion of aluminous earth. When the loſs is only from twenty to ten, the land may be conſidered as only ſlightly abſorbent and retentive, and the ſiliceous earth as probably moſt abundant.

4. *The Separation of Stones, Gravel, and vegetable Fibres from Soils.*—None of the looſe ſtones, gravel, or large vegetable fibres, ſhould be divided from the pure ſoil, till after the water is drawn off ; for theſe bodies are themſelves often highly abſorbent and retentive, and in conſequence influence the fertility of the land. The next proceſs, however, after that of heating, ſhould be their ſeparation, which may be eaſily accompliſhed by the ſieve, after the ſoil has been gently bruiſed in a mortar. The weights of the vegetable fibres of wood, and of the gravel and ſtones, ſhould be ſeparately noted down, and the nature of the laſt aſcertained ; if calcareous, they will efferveſce with acids ; if ſiliceous, they will be ſufficiently hard to ſcratch glaſs ; and if of the common aluminous claſs of ſtones, they will be ſoft, eaſily ſcratched with a knife, and incapable of efferveſcing with acids.

5. *Separation of the Sand and Clay, or Loam, from each other.*—The greater number of ſoils, beſides gravel and ſtones, contain larger or ſmaller proportions of ſand of different degrees of fineneſs ; and it is a neceſſary operation, the next in the proceſs of analyſis, to detach them from the parts in a ſtate of more minute diviſion, ſuch as clay, loam, marle, and vegetable and animal matter, and the matter ſoluble in water. This may be effected in a way ſufficiently accurate, by boiling the ſoil in three or four times its weight of water, and, when broken down and cool, by agitating the parts of the ſoil in the water, and then letting them reſt. In this caſe, the coarſe ſand will generally ſeparate in a minute, and the finer in two or three minutes, whilſt the minutely divided earthy, animal, or vegetable matter will remain in a ſtate of mechanical ſuſpenſion for a much longer time ; ſo that by pouring the water from the bottom of the veſſel, after one, two, or three minutes, the ſand will be principally ſeparated from the other ſubſtances, which, with the water containing them, muſt be poured into a filter, and after the water has paſſed through, collected, dried, and weighed. The ſand muſt likewiſe be weighed, and their reſpective quantities noted down. The water of lixiviation muſt be preſerved, as it will be

found to contain ſaline matter, and the ſoluble animal and vegetable matters, if any exiſt in the ſoil.

6. *Examination of the Sand.*—By the proceſs of waſhing and filtration, the ſoil is ſeparated into two portions, the moſt important of which is generally the finely divided matter. A minute analyſis of the ſand is ſeldom or never neceſſary, and its nature may be detected in the ſame manner as that of the ſtones or gravel. It is always either ſiliceous ſand, or calcareous ſand, or a mixture of both. If it conſiſts wholly of carbonate of lime, it will be rapidly ſoluble in muriatic acid, with efferveſcence; but if it conſiſt partly of this ſubſtance, and partly of ſiliceous matter, the reſpective quantities may be aſcertained by weighing the reſiduum after the action of the acid, which muſt be applied till the mixture has acquired a ſour taſte, and has ceaſed to effervеſce. This reſiduum is the ſiliceous part: it muſt be waſhed, dried, and heated ſtrongly in a crucible; the difference between the weight of it and the weight of the whole, indicates the proportion of calcareous ſand.

7. *Examination of the finely divided Matter of Soils, and Mode of detecting mild Lime and Magneſia.*—The finely divided matter of the ſoil is uſually very compound in its nature; it ſometimes contains all the four primitive earths of ſoils, as well as animal and vegetable matter; and to aſcertain the proportions of theſe with tolerable accuracy is the moſt difficult part of the ſubject. The firſt proceſs to be performed, in this part of the analyſis, is the expoſure of the fine matter of the ſoil to the action of the muriatic acid. This ſubſtance ſhould be poured upon the earthy matter in an evaporating baſon, in a quantity equal to twice the weight of the earthy matter; but diluted with double its volume of water. The mixture ſhould be often ſtirred, and ſuffered to remain for an hour, or an hour and a half, before it is examined. If any carbonate of lime or magneſia exiſt in the ſoil, they will have been diſſolved in this time by the acid, which ſometimes takes up likewiſe a little oxyd of iron; but very ſeldom any alumine.

The fluid ſhould be paſſed through a filter; the ſolid matter collected, waſhed with rain-water, dried at a moderate heat, and weighed. Its loſs will denote the quantity of ſolid matter taken up. The waſhings muſt be added to the ſolution, which, if not ſour to the taſte, muſt be made ſo by the addition of freſh acid, when a little ſolution of common pruſſiat of potaſh and iron muſt be mixed with the whole. If a blue precipitate occurs, it denotes the preſence of oxyd of iron, and the ſolution of the pruſſiat muſt be dropped in till no farther effect is produced. To aſcertain the quantity, it muſt be collected in the ſame manner as other ſolid precipitates, and heated red; the reſult is oxyd of iron, which may be mixed with a little oxyd of manganeſum. Into the fluid freed from oxyd of iron, a ſolution of neutralized carbonate of potaſh muſt be poured till all the effervеſcence ceaſes in it, and till its taſte and ſmell indicate a conſiderable exceſs of alkaline ſalt. The precipitate that falls down is carbonate of lime; it muſt be collected on the filter, and dried at a heat below that of redneſs. The remaining fluid muſt be boiled for a quarter of an hour, when the magneſia, if any exiſt, will be precipitated from it, combined with carbonic acid, and its quantity is to be aſcertained in the ſame manner as that of the carbonate of lime. If any minute proportion of alumine ſhould, from peculiar circumſtances, be diſſolved by the acid, it will be found in the precipitate with the carbonate of lime, and it may be ſeparated from it by boiling it for a few minutes with ſoap-ley, ſufficient to cover the ſolid matter. This ſubſtance diſſolves alumine, without acting upon carbonate of lime. Should the finely divided ſoil be ſufficiently calcareous to effervеſce very ſtrongly with acids, a very ſimple method may be adopted for aſcertaining the quantity of carbonate of lime, and one ſufficiently accurate in all common caſes. Carbonate of lime, in all its ſtates, contains a determinate proportion of carbonic acid, *i. e.* about 45 *per cent.*, ſo that when the quantity of this elaſtic fluid, given out by any ſoil during the ſolution of its calcareous matter in an acid, is known, either in weight or meaſure, the quantity of carbonate of lime may be eaſily diſcovered. When the proceſs by diminution of weight is employed, two parts of the acid and one part of the matter of the ſoil muſt be weighed in two ſeparate bottles, and very ſlowly mixed together, till the effervеſcence ceaſes; the difference between their weight, before and after the experiment, denotes the quantity of carbonic acid loſt; for every four grains and a half of which, ten grains of carbonate of lime muſt be eſtimated. The beſt method of collecting the carbonic acid, ſo as to diſcover its volume, is by the pneumatic apparatus, the conſtruction and application of which are deſcribed below. The eſtimation is, for every ounce meaſure of carbonic acid, two grains of carbonate of lime. The bulk may be meaſured by the quantity of water which is diſplaced.

8. *Mode of aſcertaining the Quantity of inſoluble finely divided animal and vegetable Matter.*—After the fine calcareous matter of the ſoil has been acted upon by muriatic acid, the next proceſs is to aſcertain the quantity of finely divided inſoluble animal and vegetable matter that it contains. This may be done with ſufficient preciſion, by heating it to ſtrong ignition in a crucible over a common fire, till no blackneſs remains in the maſs. It ſhould be often ſtirred with a metallic wire, ſo as to expoſe new ſurfaces continually to the air: the loſs of weight that it undergoes denotes the quantity of the ſubſtance that it contains deſtructible by fire and air. It is not poſſible, without nice and difficult trials, to aſcertain whether this ſubſtance is wholly animal or vegetable matter, or a mixture of both. When the ſmell emitted during the incineration is ſimilar to that of burnt feathers, it is a certain indication of ſome animal matter, or that which is analogous to it; and a copious blue flame at the time of ignition, almoſt always denotes a conſiderable proportion of vegetable matter. In caſes when the experiment is needed to be very quickly performed, the deſtruction of the decompoſible ſubſtances may be aſſiſted by the agency of nitrate of ammonia, which at the time of ignition may be thrown gradually upon the heated maſs in a quantity of twenty grains for every hundred of reſidual ſoil. It promotes the diſſipation, or affords the principle neceſſary to the combuſtion of the animal and vegetable matter, which it cauſes to be converted into elaſtic fluids; and it is itſelf at the ſame time decompoſed and loſt.

9. *Mode of ſeparating aluminous and ſiliceous Matter and Oxyd of Iron.*—The ſubſtances remaining after the decompoſition and deſtruction of the vegetable and animal matter, are generally minute particles of earthy matter, containing uſually alumine and ſilex, with combined oxyd of iron, or of manganeſe. To ſeparate theſe from each other, the ſolid matter ſhould be boiled for two or three hours with ſulphuric acid, diluted with four times its weight of water; the quantity of the acid ſhould be regulated by the quantity of ſolid reſiduum to be acted upon, allowing for every hundred grains two drachms, or one hundred and twenty grains of acid. The ſubſtance remaining after the action of the acid may be conſidered as ſiliceous; and it muſt be ſeparated, and its weight aſcertained, after waſhing and drying in the uſual manner.

The alumine and the oxyd of iron and mangane$\int$e, if they exiſt, are all diſſolved by the ſulphuric acid; they may be ſeparated by carbonate of ammonia, which, added to exceſs, throws down the alumine, and leaves the oxyd of iron in ſolution, and this ſubſtance may be ſeparated from the liquor by boiling, by ſuccinate of ammonia uſed to exceſs, which precipitates the oxyd of iron, and by ſoap-ley, which diſſolves the alumina, but not the oxyd of manganeſum: the weights of the oxyds aſcertained after they have been heated to redneſs, will denote their quantities. Should any magneſia and lime have eſcaped ſolution in the muriatic acid, they will be found in the ſulphuric acid; this, however, is ſcarcely ever the caſe; but the proceſs for detecting them, and aſcertaining their quantities, is the ſame in both inſtances. The method of analyſis by ſulphuric acid, is ſufficiently preciſe for all uſual experiments; but if very great accuracy be an object, dry carbonate of potaſh muſt be employed as the agent, and the reſiduum of the incineration muſt be heated red for half an hour, with four times its weight of this ſubſtance, in a crucible of ſilver, or of well-baked porcelain. The maſs obtained muſt be diſſolved in muriatic acid, and the ſolution evaporated till it is nearly ſolid; diſtilled water muſt then be added, by which the oxyd of iron and all the earths, except ſilex, will be diſſolved in combination as muriates. The ſilex, after the uſual proceſs of lixiviation, muſt be heated red; the other ſubſtances may be ſeparated in the ſame manner as from the muriatic and ſulphuric ſolutions. This proceſs is the one uſually employed by chemical philoſophers for the analyſis of ſtones.

10. *Mode of diſcovering ſoluble, animal, and vegetable Matter, and ſaline Matter.*—If any ſaline matter, or ſoluble, vegetable, or animal matter, is ſuſpected in the ſoil, it will be found in the water of lixiviation uſed for ſeparating the ſand. This water muſt be evaporated to dryneſs in an appropriate diſh, at a heat below its boiling point. If the ſolid matter obtained is of a brown colour, and inflammable, it may be conſidered as partly vegetable extract. If its ſmell, when expoſed to heat, be ſtrong and fetid, like burnt feathers, it contains animal, mucilaginous, or gelatinous ſubſtance; if it be white and tranſparent, and not deſtructible by heat, it may be conſidered as principally ſaline matter, the nature of which may be known by the proper teſts. Nitrate of potaſh (nitre) or nitrate of lime, is indicated in this ſaline matter, by its ſcintillating with burning coal. Sulphate of magneſia may be detected by its bitter taſte; and ſulphate of potaſh produces no alteration in ſolution of carbonate of ammonia, but precipitates ſolution of muriate of barytes.

11. *Mode of detecting Sulphate of Lime (Gypſum) and Phoſphate of Lime in Soils.*—Should ſulphate or phoſphate of lime be ſuſpected in the entire ſoil, the detection of them requires a particular proceſs upon it. A given weight of it, 400 grains for inſtance, muſt be heated red for half an hour in a crucible, mixed with one-third of powdered charcoal. The mixture muſt be boiled for a quarter of an hour, in half a pint of water, and the fluid collected through the filter, and expoſed for ſome days to the atmoſphere in an open veſſel. If any ſoluble quantity of ſulphate of lime (gypſum) exiſted in the ſoil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion. Phoſphate of lime, if any exiſt, may be ſeparated from the ſoil after the proceſs for gypſum. Muriatic acid muſt be digeſted upon the ſoil, in quantity more than ſufficient to ſaturate the ſoluble earths, the ſolution muſt be evaporated, and water poured upon the ſolid matter. This fluid will diſſolve the compounds of earths with the muriatic acid, and leave the phoſphate of lime untouched. It would not, the writer ſays, fall within his limits to detail any proceſſes for the detection of ſubſtances which may be accidentally mixed with the matters of ſoils. Metallic oxyds and earths of other kinds are, now and then, found in them, but theſe in too minute quantities to bear any relation to fertility or barrenneſs, and the ſearch for them would make the analyſis much more complicated without rendering it more uſeful.

12. *Statement of Reſults and Products.*—When the examination of a ſoil is completed, the products ſhould be claſſed, and their quantities added together; and if they nearly equal the original quantity of ſoil, the analyſis may be conſidered as accurate. It muſt, however, be noticed, that when phoſphate or ſulphate of lime are diſcovered by the independent proceſs juſt ſtated, a correction muſt be made for the general proceſs, by ſubtracting a ſum equal to their weight from the quantity of carbonate of lime obtained by precipitation from the muriatic acid. In arranging the products, the form ſhould be in the order of the experiments by which they were obtained. Thus, 400 grains of a good ſiliceous ſandy ſoil may be ſuppoſed to contain, and have been actually found to contain as follows:

	Grains.	
Of water of abſorption - -	18 to	19
Of looſe ſtones and gravel, principally ſiliceous,	42	53
Of undecompounded vegetable fibres -	10	14
Of fine ſiliceous ſand - - -	200	212
	270	298

Of minutely divided matter ſeparated by filtration, and conſiſting of

	Grains.	
Carbonate of lime - - -	19 to	25
Carbonate of magneſia - - -	3	4
Matter deſtructible by heat, principally vegetable,	15	10
Silex - - - - -	21	40
Alumine - - - -	13	32
Oxyd of iron - - - - -	5	4
Soluble matter, principally ſulphate of potaſh, common ſalt, and vegetable extract, -	3	5
Gypſum - - - -	2	3
Phoſphate of lime - - -	0	2
	81	125
	298	270
Amount of all the products in the different caſes	379	395
Loſs - - - - -	21	5

In one of theſe inſtances the loſs is ſuppoſed ſmall; but in general, in actual experiments, it will be found much greater, as ſeen in the other, in conſequence of the difficulty of collecting the whole quantities of the different precipitates, and the preſence of more moiſture than is accounted for in the water of abſorption, and the loſs of it in the different proceſſes. But when it is within thirty for four hundred grains, there is no reaſon to ſuſpect any want of due preciſion in the proceſſes.

13. *This general Method of Analyſis may in many Caſes be much ſimplified.*—When the experimenter is become acquainted with the uſe of the different inſtruments, the properties of the re-agents, and the relation between the external and chemical qualities of ſoils, he will ſeldom find it neceſſary to perform, in any one caſe, all the proceſſes that have been deſcribed. When his ſoil, for inſtance, contains no notable

proportion of calcareous matter, the action of the muriatic acid, 7, may be omitted. In examining peat ſoils, he will principally have to attend to the operation by fire and air, 8; and in the analyſis of chalks and loams, he will often be able to admit the experiment by ſulphuric acid, 9. In the firſt trials that are made by perſons unacquainted with chemiſtry, they muſt not expect much preciſion of reſult. Many difficulties will be met with: but in overcoming them, the moſt uſeful kind of practical knowledge will be obtained, and nothing is ſo inſtructive in experimental ſcience as the detection of miſtakes. The correct analyſt ought to be well grounded in chemical information; but perhaps there is no better mode of gaining it than that of attempting original inveſtigations. In purſuing his experiments, he will be continually obliged to learn from books the hiſtory of the ſubſtances he is employing or acting upon; and his theoretical ideas will be more valuable, in being connected with practical operations, and acquired for the purpoſe of diſcovery.

Apparatus for the Analyſis of Soils.—The neceſſary apparatus and other conveniences for effecting the above purpoſes are different: the firſt conſiſts of a retort in connection with other veſſels, ſo as to form a peculiar pneumatic apparatus, by which the quantity of elaſtic fluid that is given out during the action of an acid on calcareous ſoils may be collected and meaſured, the bulk of it being aſcertained by the amount of the water that is diſplaced. The different parts of the apparatus are theſe. A bottle or retort for receiving and containing the ſoil; another containing the acid, furniſhed with a ſtop-cock; a tube connected with a flaccid bladder; a bottle for containing the bladder; and a graduated meaſure. When this contrivance is uſed, a given quantity of ſoil is introduced into the firſt bottle; the ſecond is filled with muriatic acid, diluted with an equal quantity of water, and the ſtop-cock being cloſed, is connected with the upper orifice of the firſt bottle, which is ground to receive it. The tube connected with the flaccid bladder is introduced into the lower orifice of the ſame bottle, and the bladder, in its flaccid ſtate, placed into the bottle for containing it, which is filled with water. The graduated meaſure is put under the tube of the bottle for containing the bladder. When the ſtop-cock of the ſecond bottle is turned, the acid flows into the firſt, and acts upon the ſoil; the elaſtic fluid which is generated paſſes through the tube connected with the flaccid bladder into the bladder, and diſplaces a quantity of water in the bottle for containing the bladder equal to it in bulk; and this water flows through the tube of the laſt bottle into the graduated meaſure; and gives by its volume the indication of the proportion of carbonic acid diſengaged from the ſoil; for every ounce meaſure of which two grains of carbonate of lime may be eſtimated or allowed, as already ſuggeſted.

The other things are, an Argand's lamp and ſtand; funnels for the purpoſe of filtering; and bottles for containing the different re-agents, as previouſly noticed.

Another method of deciding in regard to the nature, properties, and qualities of ſoils, but which is far inferior to that of chemical analyſis, though moſt frequently had recourſe to in purchaſing of land, is that of attending to the growth and colour of the vegetables which grow upon or cover it; but it requires a ſound judgment, much experience, and a correct eye in the execution.

It is cuſtomary, alſo, for farmers to have recourſe to other marks in forming their judgments of ſoils, ſuch as their appearances or colours, and their adheſion, tenacity, or looſeneſs and friability. Thus, the hazel-brown ſhews a valuable ſort of loamy ſoil, and the reddiſh ſandy mould a good one of the lighter kind. The wetneſs of lands ſhould likewiſe be well conſidered, ſo far as it is connected with the nature of the ſoil. From the full conſideration of all theſe different circumſtances, with a competent experience, a tolerably correct deciſion may in general be formed in reſpect to the nature of land. See FARM.

Sir Humphrey Davy, in his "Elements of Agricultural Chemiſtry," conſiders it as a vain labour to attempt to claſs ſoils with ſcientific accuracy. He thinks, too, that the diſtinctions at preſent adopted by farmers are quite ſufficient for the purpoſes of agriculture; eſpecially if ſome degree of preciſion be had recourſe to in the application of the terms. The term ſandy, he thus conceives, ſhould never be applied to any ſoil that does not contain at leaſt ſeven-eighths of ſand; ſandy ſoils that effervеſce with acids, ſhould be diſtinguiſhed by the name of calcareous ſandy ſoil, to diſtinguiſh them from thoſe that are ſiliceous. The term clayey ſoil ſhould not be made uſe of to any land which contains leſs than one-ſixth of impalpable earthy matter, not conſiderably effervеſcing with acids: the word loam ſhould be limited to ſoils containing at leaſt one-third of impalpable earthy matter, copiouſly effervеſcing with acids. A ſoil to be conſidered as peaty, ſhould contain at leaſt one-half of vegetable earthy matter. And that, in caſes when the earthy part of a ſoil obviouſly conſiſts of the decompoſed matter of one particular ſort of rock, a name derived from the rock may with propriety, it is ſuppoſed, be given to it. In this way it is imagined, that if a fine red earth be found immediately above decompoſing baſalt, it may be denominated baſaltic ſoil. If fragments of quartz and mica be found abundant in the materials of the ſoil, as is often the caſe, it may be called granitic ſoil; and the ſame thing may be done in a great number of other ſimilar caſes.

It is evident, that the greater preciſion and correctneſs there are in this buſineſs, the greater will be the advantages of the cultivators of the land or ſoil.

Diviſion of Soils.

Kinds.

1. Clayey,
2. Loamy,
3. Chalky,
4. Gravelly,
5. Sandy,
6. Peaty or moſſy,
7. Boggy and heathy, or
8. Moory,

However, theſe ſeveral diviſions muſt evidently be capable of being ſubdivided under various other heads, according to the differences in the conſtituent ingredients.

Clayey Soils.—It may be remarked, that as clay is ſeldom found in any thing near a ſtate of purity in ſoils, it is plain that there muſt be much difference in the ſoils in which it is the chief conſtituent principle, according to the proportion and nature of the admixture that has taken place. Theſe ſoils are moſtly found to contain an intermixture of different earthy materials, with various animal, vegetable, and mineral ſubſtances, and often blended with conſiderable quantities of ſiliceous and ſandy matters. It has been obſerved, in a late practical work, on the authority of Dr. Anderſon, that it is upon this account that the clayey ſoils of ſome diſtricts are ſo abundantly fruitful and productive, while thoſe of others are inſuperably ſterile and refractory. Farmers, or thoſe engaged in cultivating land, for the moſt part being only acquainted or converſant with earth or mould, as it offers itſelf to their attention in the groſs or whole, have not, he thinks, been led to remark the aſtoniſhing diverſity that takes place in reſpect to the properties of clays and other bodies that are united with them as primitive and conſtituent parts of ſoils, in their original and native ſtates; but having found that they all agreed in poſſeſſing the property of imbibing and retaining moiſture, and thereby of becoming ſoft and ductile, have, probably too haſtily, concluded them to have in ſome meaſure a ſimilarity in their other qualities. In this way erroneous notions have frequently, he ſuppoſes, been engendered reſpecting ſoils in which theſe ſubſtances abound. For it is well aſcertained, from the uſe of clays in ſtates of greater purity, that there are eſſential differences in their qualities. There are ſome ſorts, as that which is denominated fuller's-earth, and ſeveral of the ſoft boles that have the coheſive property in but a very ſlight degree; while others, ſuch as thoſe which are termed *tills*, are ſo extremely tenacious and viſcid, as to be capable of being drawn out into threads: and there are ſtill others, which, from their ſoftneſs, and property of imbibing water readily, are capable of being cut with great facility by any ſharp inſtrument; while ſome other ſorts are ſo firm, hard, and compact, as ſcarcely to admit of being ſoftened by means of water. The clays which are employed for making the fineſt porcelain, and thoſe uſed in the compoſition of the more coarſe wares, are only to be met with in particular ſituations and diſtricts. This fully ſhews that much diverſity muſt exiſt in the nature of ſoils of this deſcription, and which are perhaps far from being yet fully underſtood or aſcertained. But, beſides ſoils of this ſort differing in theſe reſpects, they have an equal diverſity in their appearances or colours, and their textures; being found in the ſtate of nature of very different colours, as red, white, blue, and yellow, and of very different degrees of compactneſs or denſity; in ſome caſes readily admitting the intermixture of other matters to improve them; while in others they are highly refractory in this reſpect, being with very great difficulty made to unite with them. It is plain, therefore, that in the firſt of theſe varieties of clayey ſoils, the proportion of ſiliceous or ſandy material muſt be conſiderably larger than in the latter, in relation to that of the clayey part. But notwithſtanding the above, all theſe deſcriptions of ſoils are found to poſſeſs ſome degree or other of the ſtiff or heavy quality, according to which, with proper attention to their other circumſtances, their cultivation and improvement muſt be conducted and carried on.

The chemical analyſis of different ſorts of clays, executed by the late ingenious Mr. Somerville, and detailed in his valuable Survey of Eaſt Lothian, ſerves to place the nature of ſuch ſoils in a clear point of view.

The intelligent writer concludes, that the experiments which he has deſcribed ſeem to prove, that the principal conſtituent parts of fertile clays are alkaline ſalts, calcareous earth, and oil, together with a very ſmall proportion of iron. In the ſtrongeſt and moſt retentive clays, the proportion of oil is greater, and that of alkaline ſalt and calcareous earth leſs, than in ſuch as approach nearer to the nature of loam; except in the experiments, when the clay was taken from the top of a lime-rock, in which it was found to contain leſs oil than any of the others, and more calcareous earth than either loam or any of the other clays: it differs further in containing no iron. And it is ſuppoſed that *tills* (*i. e.* a name given in Eaſt Lothian to ſuch of the thin clays as are blue, yellow, and red coloured, and, at the ſame time, barren) contain the ſame principles as other clays, with the exception of calcareous earth, of which they appear to be entirely deſtitute; in place of which, they contain a very great proportion of iron, which ſeems to be the principal cauſe of their barrenneſs; and, according as they contain more or leſs of it, they are more or leſs ſterile.

But in whatever manner theſe ſoils may be conſtituted, they invariably require greater power, labour, and attention, to bring them into a condition proper for the purpoſes of the farmer, than thoſe of moſt other ſorts. They are, in fact, naturally ſterile, from their adhering together in maſſes; unleſs where the ſummer is ſo divided between rain and ſun-ſhine, that they are kept in a medium between drought and wetneſs, a circumſtance that rarely happens in this uncertain climate. Where the ſeaſons are wet, the plants growing on ſuch ſoils are inundated; the cloſeneſs of the clay not admitting the water to ſoak into the ground: and in a dry ſeaſon the ground becomes ſo ſolid, that the roots of plants cannot penetrate or ſpread themſelves in it. A tolerably accurate idea of the fertility or barrenneſs of clayey ſoils may be obtained, by regarding the appearance of the different plants, as they vegetate: if they appear lively and vigorous, a favourable opinion may be drawn; the reverſe, of courſe, follows, if they appear languid, unhealthy, and ſtinted in their growth.

However, the clayey ſoils are thought to contain more of the food of plants than almoſt any other; as, without much alteration, ſuch lands will produce good crops of graſs, provided care be taken not to feed them too cloſely, nor to admit cattle into them in the ſpring. In order, however, to bring them into tillage, it is neceſſary that ſuch ſoils ſhould be altered by the admixture of ſuch ſubſtances as tend to open the ſoil, and to break the coheſion of its particles, and which ſupply vegetable matter in many caſes. When once theſe objects are accompliſhed, the land will become highly valuable, retaining manure excellently, and never returning to its former ſtate of barrenneſs. Theſe ſorts of ſoils are conſequently capable of much improvement, by the judicious application of ſubſtances and manures of ſuitable kinds, and a proper courſe of tillage huſbandry. And in regard to the former, pounded limeſtone, gravel, ſand, and calcareous marle, are the moſt uſeful articles in the view of altering the texture; and the beſt ſeaſon for laying them on is in the beginning of the year, as it is only during winter, while the ſurface is frozen, that teams can ſtir upon them. Where thoſe foſſile ſubſtances cannot be procured, and the vegetable principle is deficient, a mixture of dung and ſand, eſpecially that from the ſea-ſhores, will contribute greatly to fertilize the ground. But the application of lime alone has, in many inſtances, been attended with great advantage; though ſome farmers diſapprove of it, on account of its being apt to cake, and not mixing intimately with the ſoil. However, a variety of other ſubſtances may likewiſe be employed, in caſes where a deficiency of thoſe foſſils exiſt, ſuch as compoſts of chalk and dung, tanners' bark, ſea-mud, and other materials that promote a ſtrong fermentation: and it has been found by experience, that chalk and theſe together not only enrich the ſoil, but alſo make it produce earlier crops than it did before. The chalk, indeed, thus laid upon the land at length ſubſides, ſettles as deep as the plough goes, and is then of no further value in opening the land; but it may be recovered and brought up again to the ſurface, by ploughing ſomewhat deeper than ordinary, after which it will produce its former good effects. Gravel from neighbouring ſoils may alſo be carted upon clayey ſoils, to which may be added ſea or pit-coal aſhes, duſt from ſaw-pits, chips, and rubbiſh from the back yards of houſes, ſtraw, and ſtubble, rotten wood, burnt clay, peat aſhes, and perhaps *gypſum*, or plaſter of Paris in ſome caſes. This laſt ſubſtance, as well as thoſe of lime and other calcareous matters, may alſo be found uſeful in ſuch ſoils of this ſort as have a ſour tendency, by neutralizing and correcting ſuch acidity, by which they may be rendered more proper for the growth of crops of both the grain and graſs kind.

And it has been obſerved in the third volume of the Farmer's Magazine, that the thinner kinds of theſe lands are almoſt univerſally poor: the colder and more unkindly bottoms ſuch ſoils are found upon muſt naturally render them ſo. And that ſuch land is badly adapted to bear much fatigue of the plough, either in winter or ſummer: that being the caſe, neither autumn nor late ſpring ploughing can be depended on by the farmers; the land being ſo delicate of itſelf, it cannot reſiſt the alternate froſt and rain in winter; and if it happen to be a wet ſeaſon before ſeedtime, the proſpect of a crop muſt be very unpromiſing; and by the latter, if drought come on, it cannot fail of penetrating to the bottom of the furrow; in which caſe, the grain caſt upon it muſt remain deſtitute of nouriſhment: therefore, the moſt proper ſeaſon for ploughing ſuch land is February, and the beginning of March, when the weather is dry. And further, that the ſtronger ſorts baffle the operation of the plough more than any other it encounters. The only friend that co-operates with it, in ſubduing ſuch ſoils, is ſtrong liming: without doubt, winter froſt is alſo of much benefit; on which account, the farmer is often induced to plough ſuch land early. But it ought to be remembered, that although ſalutary effects may be produced by early ploughing, when there happens to be much froſt; yet very pernicious effects muſt follow, when the winter turns out to be very wet: for it is generally underſtood that clayey ſoils, for the moſt part, lie upon a retentive bottom of the ſame nature; therefore, all the water that falls upon them muſt eaſily penetrate to the bottom, through the ſeams between the furrows: and as the ſubſoil, or bottom of the furrow, will be left with a ſmall bank on the land-ſide of the coulter cut together, with the under araſe of the back part of the furrow reſting upon it, the water muſt be prevented from running to the drain-furrow, which will prove very pernicious and hurtful to the ſoil, being too cold at the bottom, in its beſt ſtate. It may perhaps be ſaid, that the ſame danger will be incurred, at whatever period the ploughing is performed; but there is a material difference between water ſtagnating in the bottom of the furrows for four or five months, and when it only does ſo for as many weeks: therefore, wherever autumn or early winter ploughing is practiſed on ſuch ſoils, that of ſummer fallow will alſo, he thinks, be often neceſſary.

It may be noticed, that the moſt proper ſorts of crops, in the firſt ſort, are peaſe and oats; and where compoſts can be had, and applied to the ſward, ſummer fallow will be beneficial; followed by wheat and artificial graſſes: and in the latter, cabbages, wheat, beans, peaſe, and graſs-ſeeds for both hay and paſture. See CLAYEY *Land.*

Almoſt every one of the above modes of improving and bettering the qualities of clayey ſoils are practiſed with much advantage and ſucceſs, in one or other of the different places throughout the country where they are met with. In the northern parts, however, where the uſe of lime on theſe ſorts of ſoils, eſpecially the better cultivated kinds of them, is more had recourſe to than in the ſouthern, they not uncommonly apply farm-yard manure the ſame ſeaſon in which the land is limed, though not, by any means, in combination with it; as by this practice the lime is believed to act more powerfully, as well as more effectually, and with far greater expedition, than when it is employed in the manner of compoſt, or mixture with earthy matters. It has been fully ſhewn that lime, in its active ſtate, has great power in promoting the ſolution and decay of all vegetable matters in ſoils, and, of courſe, of greatly increaſing the proportion of that ſort of material in them. In this way its readineſs in producing this ſort of matter in a large quantity, when applied to ſoils which contain a conſiderable portion of vegetable materials, is eaſily explained. And the powers of improving different kinds of clayey ſoils, in theſe methods, may be very much aided and aſſiſted by well directed modes of ſtirring and tilling ſuch lands; as where the ploughings, harrowings, and other proceſſes on them, eſpecially in the more ſtiff and retentive kinds, are frequent, and made at ſeaſons of the year in which they are neither too dry and cloddy, nor too wet and poachy, ſo that they may be well broken down and reduced in their parts, and fully expoſed to the influence of the atmoſphere. In theſe ways they are enabled to acquire a high degree of pulverization and fineneſs in their particles, by which the growth of plants upon them is greatly forwarded, and rendered more perfect. The ſeed is here to be covered in, for the moſt part, in a complete manner; the previous ploughings having been made to ſuitable depths, as the circumſtances of the lands may direct. On the thinner ſorts, where ſprings are apt to riſe, they ſhould have leſs depth than in other caſes. The tools and teams employed in working them ſhould be ſtrong, and ſo attached as to do as little injury by poaching as poſſible; ſuch ſeaſons as are neither too moiſt nor too dry being, in all caſes, choſen for the purpoſe.

Soils of this nature prevail very greatly in many diſtricts of the kingdom; and though they are improved, and brought into proper order for cultivation, with great difficulty, labour, and expence, they commonly anſwer very well in the end, by affording a long continued and very abundant produce.

2. *Loamy Soils.*—It is evident that loam, in its natural ſtate, is a ſort of earthy material, more compact than chalk, but leſs coheſive than clay. In theſe ſoils there is likewiſe much variety; ſome being ſtiff and compact; while others are more open, looſe, and porous: hence we have heavy, ſtiff, and light loams. The materials of which theſe ſoils are chiefly compoſed are thoſe of the clayey, chalky, ſandy, and gravelly kinds; on which account writers on huſbandry have denominated them clayey loams, chalky loams, ſandy loams, and gravelly loams; and ſometimes, where a ſmall portion of the oxyd or calx of iron is found mixed with the loamy material, they are termed *tilly* loams. The firſt, according to Kirwan, denotes a compound ſoil, moderately coheſive, in which the argillaceous ingredient predominates. Its coheſion is, then, greater than that of any other loam, but leſs than that of pure clay. The other ingredient is a coarſe ſand, with or without a ſmall mixture of the calcareous ingredient. It is this which farmers generally call ſtrong, ſtiff, cold, and heavy loam, in proportion as the clay abounds with it. And the ſecond indicates a loam formed of clay, coarſe ſand, and chalk; in which, however, the calcareous ingredient or chalk much predominates. It is leſs coheſive than clayey loams.

The third ſort denotes a loam in which ſand predominates: it is leſs coherent than either of the above-mentioned. Sand, partly coarſe and partly fine, forms from 80 to 90 *per cent.* of this compound. The fourth differs from the above only in containing a larger mixture of coarſe ſand, or pebbles. This and the two laſt are generally called by farmers light or hungry ſoils; particularly when they have but little depth. The fifth is generally of a dark brown or reddiſh colour, and much harder than any of the preceding: it conſiſts of clay and the calces of iron, more or leſs intimately mixed. It may be diſtinguiſhed not only by its colour, but alſo by its ſuperior weight; it ſometimes efferveſces with acids, and ſometimes not; when it does, much of the irony part may be ſeparated, by pouring it, when well dried, into ſpirit of ſalt; from which the iron may afterwards be ſeparated by alkalies or chalk. And akin to this are certain vitriolic ſoils, which, when ſteeped in water, impart to it the power of reddening ſyrup of violets. Theſe are generally of a blue colour, but redden when heated.

Further, it has been remarked by a late writer, that in proportion as the clayey principle diſappears, they recede from ſoils of that kind, and that of courſe the nearer the quality of the clayey matter comes to that of the others, the ſtronger and heavier the loamy ſoils muſt be. And that the differences in the lightneſs and friability of the ſoils of this claſs, in a great meaſure, depend on the relative proportions of the other ingredients. Where the calcareous ingredient greatly exceeds thoſe of the ſandy or gravelly kinds, they are neither ſo light nor ſo pulverizable as where they are nearly equal, or where the ſandy or gravelly matters conſiderably predominate over it. In the latter caſe, indeed, ſuch ſoils are formed as have been denominated by practical farmers light and hungry, eſpecially where the earthy bed or ſtratum thus produced is but of little depth, and reſts on a gravelly or flinty bottom or ſub-ſoil. It is alſo added, that the variety in the colours of ſoils of the loamy kind, ſeems, in ſome inſtances, to be produced by the union or mixture of metallic ſubſtances in greater or leſs proportions, and in more cloſe or more lax ſtates of combination with them; in others, by the prevalence of acid impregnations. The colour in the firſt caſe is for the moſt part reddiſh, approaching to brown; in the latter it is commonly blueiſh, changing by heat to a ſlight red. But theſe are not, he ſuppoſes, the only cauſes that influence the colour of theſe ſoils; they are much altered in their appearances, as well as other qualities, by the different proportions of vegetable or animal matter which they contain, and the different ſtates of decompoſition and decay to which they have been carried by length of time, cultivation, and other means. In ſituations, it is ſaid, where this ſort of ſoil has been but little diſturbed, and conſequently little changed by the artificial additions of either animal or vegetable ſubſtances, and thoſe which it naturally contained not having advanced to the ſtage of perfect ſolution and decay, it is generally found of a light brown or hazel colour; but where much culture has been employed for a length of time, and large applications of animal and vegetable matters frequently made, the natural and artificial materials of theſe kinds, having proceeded more nearly to the ſtate of perfect diſſolution and deſtruction, it has an appearance that approaches to that of black. And it is added, that from theſe various circumſtances, the properties of the ſoils are likewiſe conſiderably altered and affected. Such ſoils of this kind as are met with in extenſive tracts on the borders of the ſea, and of large rivers communicating with it, are generally rich and fertile, being moſtly compoſed of a fine ſort of ſand, calcareous matter in a high ſtate of tenuity from the attrition or rubbing down of different kinds of ſhells and other marine productions, and a rich matter proceeding from the diſſolution of various luxuriant ſea plants, and innumerable ſorts of animal exuviæ. Theſe alluvial materials being all gradually depoſited and incorporated with the natural loamy earth of the ſituations in which they are found.

There are ſoils of this ſort, in particular ſituations near the ſea-coaſts, which are extremely rich, being a great deal conſtituted or compoſed of layers of oyſter and cockle-ſhells, in combination with their earthy matters, and much impregnated with marine ſalt from the overflowings of the ſea, which ſeems to have been highly beneficial to them, when acted upon, for ſome length of time, by the air of the atmoſphere, in the production of grain as well as other crops. In theſe caſes, this ſaline quality would appear to be entangled in a peculiar ſort of loamy ſubſtance, very different from any which are met with in upland ſituations. The richeſt loamy ſoils in ſuch places are moſtly compoſed, in a great meaſure, of ſand in mixture with a portion of clay, and are, from this quantity of ſand, very friable in their nature. But with the ſoils in theſe particular caſes, it is very different; as whatever degree of friability they may poſſeſs, ſeems to ariſe from the fermentative power, which is cauſed by the action of the atmoſphere on ſubſtances that abound with mucilaginous matters. They fall, it is ſaid, when expoſed to the changes of the weather, into dies, and are more like the cryſtallized forms of mud drying in the ſun, than the crumbling looſeneſs of common loams. There is very little appearance of any ſand in them; the particles of which they are compoſed are ſo very fine, that it would be readily imagined, they would eaſily become an impalpable powder; but, on the contrary, they are capable of ſuch adheſion, that a clod will often become very hard. Conſequently they appear to be compoſed of clay, very fine ſand, a mucilaginous principle which ferments with rain and warmth, and the ſaline quality which is derived from their origin and peculiarity of ſituation. When crumbled in the hand, they yield a ſtrong ſcent, ſo that the volatile alkali would probably be diſcovered by chemical trials, it is thought, in them. Soils of this loamy kind are met with in Foulneſs iſland, in Eſſex, and ſome other ſimilar ſituations. Their natural fertility is often ſo very great, that the farmers are but little attentive to manure; nor is it commonly ventured for any ſort of grain, as it throws up too much ſtraw, without increaſing the quantity of corn. It might, however, probably be applied for beans, or cabbages, where they were the previous crops, with much advantage.

This ſort of excellent loam is ſuppoſed utterly incapable of being formed or attained by any kind of artificial means: the great elaboratory of nature in this, as in ſo many other caſes, leaves, it is thought, the utmoſt ſkill of the chemical farmer at a vaſt diſtance.

The chemical analyſis of this ſort of ſoil, as given in the work already mentioned, by Mr. Somerville, may ſhew ſtill more fully the properties which are poſſeſſed by this kind of land.

From the experiments of this ingenious writer it would appear, that the principal conſtituent parts of the different kinds of loam, upon which they were tried, are vegetable and calcareous earths, oil, alkaline ſalts, and an inconſiderable quantity of iron. The deep black loams ſeem to contain conſiderably more oil than any of the other two, but leſs alkali and calcareous earth; which, in ſome meaſure, accounts for the inactive nature of ſome ſoils of that deſcription, which, by no means, yield crops equal to what might be expected from their appearance. The hazel-coloured loam contains leſs oil than the black, but a greater proportion of alkaline ſalts and calcareous earth; owing to which, all the loams of that deſcription in Eaſt Lothian are more active, and produce better crops than the former. The light loams, from the circumſtance of their containing leſs oily and more alkaline and calcareous matter, are the moſt active, and are commonly termed *ſharp* lands, by the farmers in that diſtrict.

Further, theſe ſoils being, in general, leſs tenacious or more friable and mellow than clays, are capable of being more eaſily improved with leſs expence and labour of team, and alſo at any ſeaſon of the year. The manure proper for ſuch ſoils varies according to their relative degree of fertility,

tility, and the greater or leſs proportion of acidity and of argillaceous and calcareous matter they contain. Thoſe loams which are contiguous to the banks of rivers, or the ſea-coaſt, are generally admitted, as has been ſeen, to be ſo fertile, as to require little additional aid from manure; but for the more heavy and adheſive kinds, a compoſt of effete lime and dung, or lime in combination with pulverized or ground bones and blood, or other animal recrements, and ſuch terrene ſubſtances as contain large quantities of ſand, may be beneficially applied in ſuch quantities as the tenacity or poverty of the land may require. Where the argillaceous principle abounds, lime alone may be ſpread on the ſoil, in order to counteract the acidity prevalent in ſuch ſoils; in the contrary caſe, or where there is an abundance of ſand, gravelly, or chalky particles duly mixed with the loams, well rotted dung, vegetable manures of different kinds, and the mud or depoſition procured from ſtagnant waters, may be ſpread to the greateſt advantage; and in caſe the loam be too friable or light, a quantity of clayey loam may be carried on the land, ſufficient to impart a proper degree of coheſion or tenacity.

In the county of Oxford they find lime uſeful on the yellow loams which are wet and ſtand in need of draining. They are rarely ſoils of much natural fertility; but lime makes them very productive in oats, and prepares them for future wheat crops; when employed in the quantity of from twenty to thirty quarters *per* acre. It anſwers greatly, likewiſe, on the red loamy ſand lands in the proportion of from fifteen to twenty-five quarters on the acre.

In Suſſex, wherever the land or ſoil tends to a reddiſh loam, or inclines to be ſandy, they have recourſe to marle, which is of a ſoapy nature, with great ſucceſs. They employ it in the quantity of from ten to twenty waggon-loads on the acre, which is from eight hundred to ſixteen hundred buſhels; applying it in the autumnal or winter ſeaſons.

Where a ſoil deficient in calcareous matter contains much *ſoluble* vegetable manure, as is the caſe in ſome ſoils of this kind, the application of quicklime to them ſhould always, according to the writer of the work on Agricultural Chemiſtry, be avoided, as it either tends to decompoſe the ſoluble matters by uniting to their carbon and oxygen, ſo as to become mild lime, or it combines with the ſoluble matters themſelves, and forms compounds having leſs attraction for water than the pure vegetable ſubſtance. And the caſe is the ſame in regard to moſt animal manures, when in ſuch ſoils; but the operation of the lime is different in different caſes, and depends upon the nature of the animal matter. With oily matters lime forms a kind of inſoluble ſoap, and then gradually decompoſes them by ſeparating from them oxygen and carbon. It combines likewiſe with the animal acids, and probably, it is ſaid, aſſiſts their decompoſition by abſtracting carbonaceous matter from them combined with oxygen; and conſequently it muſt render them leſs nutritive. It tends alſo to diminiſh the nutritive powers of albumen from the ſame cauſes; and always deſtroys, to a certain extent, the efficacy of animal manures, either by combining with certain of their elements, or by giving them new arrangements. Lime ſhould, of courſe, never be applied with animal manures to ſoils, unleſs they are too rich, or for the purpoſe of preventing noxious effluvia. It is injurious when applied in mixture with any common dung to ſoils, and tends to render the extractive matter of the dung inſoluble. But lime is conſtantly efficacious in all thoſe caſes in which fermentation is uſeful to produce nutriment from vegetable ſubſtances in ſoils.

All the ſoils of this nature are capable of affording almoſt all ſorts of crops, both thoſe of the grain and root kind, as well as thoſe of the pulſe, hemp, and flax ſort, as may be ſeen under theſe different kinds of crops.

The modes of cropping in ſome diſtricts follow, in ſome meaſure, the qualities of the loams, whether they be ſtrong, fertile, impalpable, ſandy, or of any other kinds or deſcriptions. The medium fertile loams are probably, however, on the whole, the moſt ſuited to every ſort of farming purpoſe.

3. *Chalky Soils.*—All theſe are ſoils, which are found to occupy very extenſive tracts in many of the ſouthern diſtricts of the kingdom, as well as in ſome of the more northern; and, like thoſe which have been already noticed, differ very materially both from the diverſity of the calcareous material which they contain, its proportion, and the other matters that are intermixed and blended with it, as well as the thickneſs of the earthy bed on which it reſts, and the nature of the inferior ſtratum on which the whole is depoſited. It has been ſtated by an uſeful practical writer, that matter of the calcareous kind is contained in many different ſtony ſubſtances, beſides that of chalk, as marble, limeſtone, coral, and ſhells of different kinds; and in ſtates of union with other materials, ſuch as ſand, the different ſimple earthy bodies, in different proportions, and in ſome inſtances with iron and magneſia. Its capability or power of imbibing and retaining moiſture is conſiderable, though not ſo great as that of clay. It burns to lime by proper degrees of heat, and abſorbs carbonic acid gas or fixed air in different proportions from the atmoſphere, and returns again to the ſtate of chalk or effete calcareous matter. It is found of very different degrees of hardneſs and friability, as well as of different ſtates of fineneſs or pulverization, in different ſoils of the claſs to which it belongs. It varies alſo greatly in its effects in reſpect to vegetation; from the different matters that may happen to be combined with it in its primitive or original ſtate. And it is further ſtated, that it has long been known to the practical farmer, that ſome ſorts of lime or calcareous matter may be employed in large proportions; while others cannot be uſed, except in very ſmall quantities, without doing very conſiderable injury to the ſoil with which they are incorporated. But that the long unexplored cauſe of this diverſity of effect in different limes, or calcareous matters, ſeems lately to have been placed in a more clear and ſatisfactory point of view, by the experimental attempts of an ingenious philoſopher, Mr. Tennant, who has found by repeated experiments, that that ſort of lime which is the moſt friendly to vegetation, conſiſts entirely of calcareous earth, and quickly abſorbs a large portion of carbonic acid gas or fixed air from the atmoſphere; while that which is injurious and unfriendly to the growth of plants, contains only three parts of pure calcareous earth, the other two conſiſting of magneſia; and that it abſorbs comparatively but an extremely ſmall portion of carbonic acid gas or fixed air from the ſurrounding atmoſphere. It was alſo found, that this kind of mixture of calcareous matter was very ſlow in acquiring the power of ſupporting vegetation, even after it had been converted into lime, and remained for a conſiderable length of time in the ſtate of mortar. And that the limeſtone in which there is a mixture of magneſia, is much harder, and diſſolves conſiderably more ſlowly in acids, than that which is purely calcareous. It is likewiſe ſuppoſed, that the cryſtallized ſtructure commonly obſerved in the magneſian limeſtone indicates, that it has not been formed by the accidental conjunction of the two earths, but conſtituted by their chemical union. The difficulty with which it is diſſolved by

means of acids, may alſo, it is conceived, in ſome meaſure, depend on the attraction of its different component particles to each other. It is a ſort of limeſtone, which is found to extend itſelf over very large diſtricts in the midland parts of the iſland, as well as in the more northern counties, as is obvious from the practical diſtinctions of *mild* and *hot* limes, which are in common uſe, as noticed by doctor Fenwick, in his excellent Eſſay on Calcareous Manures.

It has indeed been ſuggeſted, that theſe intereſting facts not only ſhew, that whatever ſameneſs there may be in the nature of calcareous matter, when in its pure and unadulterated ſtate, but that, as met with in ſoils, and different ſubſtances of the calcareous kinds, it has conſiderable diverſity, and when in union with magneſia, it is in a high degree prejudicial to the growth of vegetables. Later trials have, however, rendered this laſt ſuppoſition ſomewhat doubtful; therefore, until further experiments have more completely cleared up the matter, the farmer ſhould proceed with caution in the uſe of ſuch materials. But though magneſian lime or earth in its cauſtic ſtate may be injurious to vegetation, ſuch lime, in ordinary circumſtances, is not unfrequently made uſe of in moderate quantities upon ſoils of the fertile kind, in the counties of Leiceſter, Derby, and York, with good effect, and is capable of being employed in larger portions on ſoils containing more full ſupplies of vegetable matter. Magneſia, when combined with carbonic acid gas, ſeems not, it is ſaid, to be hurtful to the growth of plants, and in ſoils rich in manure, it is ſoon ſupplied with this principle, from the decompoſition of that ſubſtance.

In explanation of the above, ſir H. Davy has ſtated, that magneſia has a much weaker attraction for carbonic acid than lime, and will remain in the ſtate of cauſtic or calcined magneſia for many months, though expoſed to the air; and that as long as any cauſtic lime remains, the magneſia cannot be combined with carbonic acid, for lime inſtantly attracts carbonic acid from it. When a magneſian limeſtone is burnt, the magneſia is deprived of carbonic acid much ſooner than the lime; and if there be not much vegetable or animal matter in the ſoil to ſupply by its decompoſition carbonic acid, the magneſia will remain for a long while in the cauſtic ſtate; and in ſuch, acts as a poiſon to certain vegetables. And that more magneſian lime may be uſed upon rich ſoils, than thoſe of other kinds, ſeems to be owing to the circumſtance, that the decompoſition of the manure in them ſupplies carbonic acid. And magneſia, when mild or fully combined with carbonic acid, ſeems to be conſtantly an uſeful conſtituent part of ſoils. Carbonate of magneſia, produced by boiling the ſolution of magneſia in ſupercarbonate of potaſſa, has been thrown over graſs, and upon growing wheat and barley, ſo as to render the ſurface white, without injuring the vegetation in the ſmalleſt degree, by the ſame experimenter. Some moſt fertile diſtricts are alſo ſaid to contain mild magneſian earth, as the Lizard, in Cornwall.

This explanation has been ſomewhat confirmed by mixing and uſing four portions of the ſame ſort of ſoil in this manner: with one-twentieth of its weight of cauſtic magneſia, with another the ſame quantity of magneſia and a proportion of fat decompoſing peat, one-fourth of the weight of the ſoil; one portion was left in its natural ſtate, and one mixed with peat without magneſia. They were made towards the end of the year, and ſown in the early ſpring the next, all of them with barley; which grew very well, it is ſaid, in the pure ſoil; but better in the ſoil containing the peat and magneſia; and nearly as well in the ſoil with the peat alone; but in the ſoil mixed with magneſia alone, it roſe very feebly, and looked yellow and ſickly. The repetition of this trial was attended with ſimilar reſults; and it was found, that the magneſia in the ſoil mixed with peat became ſtrongly effervescent, while the portion in the unmixed ſoil gave carbonic acid in much ſmaller quantities. In the one caſe, it is ſuppoſed, the magneſia had aſſiſted in the formation of manure, and had become mild; in the other caſe it had acted as a poiſon on the plants.

It has alſo been found, that matter of the calcareous kind, whether effete or in the ſtate of carbonate, or in the more active one of cauſticity, as quicklime, ſeems ultimately to promote the reſolution and deſtruction of all vegetable and animal ſubſtances; but that in the latter ſtate, it acts with much greater violence on theſe materials, deſtroying their organization, and diſſipating their principles more quickly, as well as robbing them more completely of the carbonic acid gas or fixed air, which is ſo eſſential; while in the former it operates with great mildneſs, and only aids the reſolution of thoſe ſubſtances, by gently promoting the proceſs of putrefaction or decay.

It muſt be obvious, that in them the proportions of clayey, loamy, and gravelly ingredients, in combination with the calcareous matters of theſe ſoils, are materially different in different diſtricts: where the clayey and loamy are comparatively in large quantities, the heavier kinds of chalky ſoils are met with; but where the ſandy or gravelly are prevalent, the lighter ones. Material differences alſo ariſe from the earthy matter with which the calcareous ſubſtance is blended in the ſtate of ſoil, as where the quantity of this is ſmall, and not reduced into any perfect ſtate of mould, the ſoil is poor and thin; but where the thickneſs of this ſuperficial bed or layer is conſiderable, and the animal, vegetable, or other ſubſtances of which it is conſtituted, have proceeded to a more complete ſtage of decompoſition, the ſoils are more rich and heavy. Where the ſtate of the ſub-ſoil is of a compact nature, and much blended with ſiliceous or flinty matter, or has a mortary hardneſs, it is leſs favourable than where it is of a more open, brittle, or mellow powdery nature. From the calcareous material being abundant in theſe caſes, the principal intention is the changing of their textures, and the ſupplying of vegetable matter to them.

And it is found, that in the thinner or lighter calcareous ſoils, clay, or clayey marle, and the vegetable recrements depoſited and obtained in wet or ſwampy ſituations, may be beneficially applied. In thoſe of a contrary or heavier nature, the ſpreading of ſandy or clayey loams, as circumſtances may require, on them, will be attended with advantage, as altering their texture; and to theſe may be added compoſts of various vegetable and animal ſubſtances, farm-yard manure and aſhes; beſides which great attention is requiſite in breaking up theſe ſoils at the proper ſeaſon, as, if this operation be deferred till a dry ſeaſon, they become ſo bound or hard, that it will be impoſſible to work them, until they are ſoftened by rain, without very great expence both of teams and of labour in other ways. Near London, the uſe of ſoot and malt-duſt has alſo been found highly beneficial in many caſes of theſe kinds of ſoils.

Soils of this nature work, and are capable of being improved very differently, according as they are more or leſs heavy. The light and mouldering chalky lands readily admit of theſe means of amelioration, while thoſe which are of a more heavy and ſolid quality, allow of them with conſiderable difficulty and trouble. Some ſorts of crops are in a great meaſure peculiar to theſe ſorts of ſoils, as thoſe of ſaintfoin, and ſome others, but they are capable of bearing moſt kinds in their different qualities and ſtates. See Stonebrash *Land*.

Soils of this kind, though they have a barren and unpromiſing appearance, are ſometimes very productive.

4. *Gravelly Soils.*—It may be noticed, that in the gravelly materials, which conſtitute ſoils of this deſcription, there is much difference in the ſize of the ſtony particles, from that of the ſmalleſt pea, to that of the egg of a pullet. But when they become of ſtill larger dimenſions, they are denominated ſtony or rocky ſoils, according as they are in detached or connected maſſes. But the gravelly beds, of whatever kind, conſiſt in general of ſiliceous or flinty, or thoſe of the calcareous or chalky kinds, while the rocky and ſtony ſubſtances are of ſeveral different qualities. Various other matters are mixed with theſe, ſo as to conſtitute ſoils of this kind, which have much diverſity in different reſpects. Theſe are principally matters of the loamy or earthy kind, ariſing from the putrefaction and decay of different animal and vegetable materials. It is alſo remarked, that the gravelly mixture is ſometimes found to approach nearly to the ſurface, while at others it recedes conſiderably from it. In Middleſex, Mr. Middleton found, that when the ſtratum was very near the top, a full crop of yellow bloſſomed broom covered the ground; if in a ſtate of graſs, and when ploughed, an equally full crop of ſorrel. This was ſeen in the old incloſures. In ſome inſtances ſprings ariſe immediately underneath; in others they are at a great depth. The bottom or ſub-ſoil is likewiſe various; in ſome caſes it is ſtony and rocky, in others it is clayey, or a rocky gravel, and ſometimes ſand, &c. And it is added, that the open porous nature of gravelly ſoils diſpoſes them to admit moiſture very readily, as well as to part with it with equal facility; from the latter of which circumſtances they are ſubject to burn, as it is termed, in dry ſeaſons, which is not the caſe in the heavier or more retentive ſort of ſoils.

It is evident that the differences of theſe ſoils muſt be remedied according to their nature, by the uſe of different ſorts of matters of the marle kind. In caſes where the gravel is of the calcareous kind, clay, or clayey loam, may be properly employed; and a mixture of the carbonate of lime, or lime in its effete ſtate, and clay, may be found beneficial; alſo chalk, as being of the ſame nature, may be made uſe of in the ſame way. For theſe kinds of gravel, which, from their contiguity to ſprings, are apt to lie wet in the winter, there is no manure more properly adapted than chalk; which, although it does not abound with vegetable matters in any large proportion, like yard-dung, and ſome other dreſſings, is, however, an excellent preparation for them, and will, in ſome meaſure, ſupply the place of ſuch ſubſtances. It is found, from its abſorbent nature, to have a good effect, not only in counteracting the ſuperabundant moiſture of ſuch ſoils, but in leſſening their heat; by which means the diſpoſition to burn in the ſummer, ſo inimical to the growth of various crops, and to which all gravels are in ſome degree liable, is prevented: and in this laſt view, chalk, though particularly adapted to thoſe of the wet and ſpringy kind, may be applied with ſucceſs on gravels of almoſt every denomination, with the proſpect of advantage. Where there exiſts any deficiency in the vegetable and animal earthy materials, it may be properly ſupplied by dung of the farm-yard kind in its more reduced ſtate, and various other animal excrementitious matters, which may probably be employed with the greateſt benefit in the form of compoſts, with good loamy mould, aſhes, the mucilaginous and clayey depoſitions of rivers and ponds, and other ſubſtances of a ſimilar kind. Several of theſe materials, and ſome others of the animal claſs, are, however, often uſed ſeparately to the ſurface of ſoils of this ſort, with the moſt evident advantage.

Alſo much benefit may be derived to ſuch lands by a proper alteration of green vegetables, and other crops that are uſually grown upon them; as by ſuch means the moiſture is more preſerved, and the ſoils more guarded againſt injury. In the Agricultural Survey of Hertfordſhire, Mr. Young ſpeaks of a poor ſort of gravelly ſoil, the characteriſtics of which are wetneſs, or ſpewineſs, as the farmer terms it, from many ſprings; moſt of which are ſulphury, and extremely unfriendly to vegetation, abounding more or leſs with ſmooth blue pebbles, which, at various depths, are conglomerated by ſulphury clay into plum-pudding ſtones; in ſome places ſo near the ſurface as to impede the plough, if ſet but for an inch or two at a greater depth than the old ſcratchings of bad ploughmen: it is ſtiff, without a matrix for the roots of plants; and ſharp and burning even in the immediate vicinity of ſprings: it has much ſticky clay in the compoſition, but of a moſt ſterile nature. He hollow-drained many acres; but as he was obliged to employ the pick-axe, the expence was too great; and he found that the ploughing it into high ridges was conſiderably the beſt way of draining it. When it has been drained, manures have then a great effect for a time; but ſuch was the voracity of the ſoil, that the benefit of manuring was ſoon loſt, even when it had been laid down for paſture ſome years, as a preparation for corn; the beſt improvement that can, he ſuppoſes, be made on it, when cultivated for ſuch a purpoſe. But it is ſuggeſted by Mr. Walker, that this ſoil is beſt adapted to wood; for he was ſurpriſed to ſee the hedges thriving with great luxuriance on land not worth cultivation.

Lime, in mixture with good mould, has been found uſeful in Oxfordſhire, on hot gravelly land. It does very well alone, but not equal to where it is employed in combination with ſome ſort of earthy material. In the lighter kinds of gravels, the clayey marles are alſo frequently of very great utility; and in thoſe of the heavier deſcription, the calcareous ſort may often be employed with equal benefit. When well mixed up, and blended with different earthy materials, they may both be laid upon gravelly ſoils with the beſt effects, in many caſes.

By theſe different means of improving the textures and qualities of theſe kinds of ſoils, they have been ſo much altered and amended in the nature and arrangement of their parts, as to be capable of affording good crops of many different ſorts, as well as of enduring the ſummer heats, without being ſubject to become too dry or burnt up by them.

5. *Sandy Soils.*—It is ſtated that theſe are a deſcription of ſoils, which ſeem to have been formed gradually by the reduction of different ſorts of hard bodies in nature, particularly thoſe of the calcareous, ſiliceous, and ſtony ſorts, the particles being brought into different ſtates of fineneſs, being in ſome caſes extremely minute. They vary equally in their colours in different inſtances, being ſometimes perfectly white, browniſh, yellow, and red. The differences in the quantities in which other ſorts of matter enter into their compoſitions, afford conſiderable variety in their weights, tenacity, and different other properties. In ſome diſtricts, ſoils of this ſort exiſt of different kinds, from the lighteſt ſpecies of loam to the naked ſand compoſed entirely of ſmall flints, and in all of them there is a mixture of earth; according to the proportion of which, they are more or leſs favourable to vegetation.

And it has been remarked by the late Mr. Somerville, that, in Eaſt Lothian, the whole of the ſandy ſoil is evidently ſuperinduced, or placed upon the land; the bottom upon which it is laid being uniformly of the ſame quality with the circumjacent grounds. The origin of this ſand, which is accumulated upon ſeveral parts of the coaſt, is owing, it is ſuppoſed, to two cauſes: the firſt, and that which no doubt has produced the greateſt part of it, has been the waſhing away of many points of land by the ſea, by which the coaſt, formerly very much indented, is now rendered pretty uniform, and brought nearer to a regular figure: the ſecond cauſe of its formation has ariſen from the waſting of the ſoil in the interior, during heavy falls of rain, by which great quantities have been brought from the higher grounds, and either depoſited in places where the current has been leſs rapid, or carried along with the ſtream to the ſea. The laſt, however, is a rare occurrence, unleſs in ſituations where the land declines very rapidly towards the ſhore. In that county, however, it is evident that the whole of the land upon the coaſt has ariſen from the waſting and waſhing away of different points of land, while that in the interior has been produced by the waſhing of the rivers. It is remarked by a writer mentioned above, that in caſes where the proportions of clayey, loamy, or other earthy ſubſtances with which they are mixed, approach nearly to that of the ſand, the heavier ſorts of ſandy ſoils are formed; but that where theſe enter only in very ſmall quantities, the light ſandy ſoils are formed; and where they are hardly met with at all, the ſoil is a looſe blowing ſand, moſt commonly of a white or browniſh appearance. And it is added, that the portions of vegetable matters, that are intermixed with different ſoils of the ſandy kind, are not leſs various than thoſe of the clayey and loamy, from which conſiderable differences of quality are produced. Theſe differences in their textures and compoſitions alſo introduce others, which reſpect their powers of admitting and retaining heat and moiſture. The openneſs and want of adherence in ſuch ſoils, while they allow of the admiſſion of heat and water more readily, permit them to be carried off with greater eaſe and expedition: they are, therefore, leſs permanently benefited by their influence than many of the cloſer and more adheſive ſoils.

But as theſe ſorts of ſoils are chiefly deficient in the calcareous, clayey, loamy, and vegetable materials, the aim of the farmer muſt be the augmentation of their coheſive property, and the ſupplying the calcareous and decayed animal and vegetable materials. They cannot, of courſe, be cultivated with advantage, without the aid of other foſſile manures to counteract their poverty, and prevent the continual evaporation of moiſture. For this purpoſe, clay and loam may be beneficially ſpread on ſandy ſoils, which may likewiſe be improved by the uſe of compoſts of animal and vegetable manure: though, where theſe cannot be obtained, good mould or earth may be employed with advantage, as alſo may peaty earth, either alone, or in combination with other matters. It has been obſerved by Dr. Fordyce, that a leſs quantity of clay is required in the improvement of light ſandy ſoils, than of ſand in the clayey ones; but whether this be a practical rule or not, the thinner and poorer ſorts of ſandy ſoils moſtly ſtand in need of a large quantity of clayey matter. And when the calcareous property prevails, clayey marles and clayey loams are moſt proper; but in caſes of its being deficient, calcareous marle and loams may be uſed with more advantage. This has been ſufficiently proved by their application in different diſtricts. A degree of tenacity or firmneſs may alſo be imparted to ſandy ſoils, by the treading of ſheep, folded upon them; while they receive much benefit from the dung and urine depoſited by thoſe animals.

And it may be noticed, that theſe different materials are proper for being laid on either alone, or in the ſtate of compoſts; but marles and clayey ſubſtances are moſtly applied in the ſtates in which they are found in nature; but the farm-yard dung, and peaty ſubſtances, in mixture with other matters.

Further, it has alſo been ſtated by the author of "Practical Agriculture," that the light, open, and porous texture of ſandy ſoils renders them much more eaſily cultivated, and kept in order, than thoſe of the ſtrong and cloſe kinds; and, conſequently, the farms where they prevail are generally large: but that, when properly prepared, they are better adapted for the growth of many ſorts of crops, ſuch as thoſe of the bulbous and tap-rooted ſorts. And they have alſo another advantage, which is that of puſhing forward the crops with more expedition. Whatever inconveniencies attend them are moſtly ſuch as proceed from the want of a ſufficient degree of coheſion among their conſtituent particles, and ſolidity of texture. On theſe accounts, they often counteract the beſt and moſt judicious management. The roots of the crops are liable to become naked and expoſed, from ſtorms and various other cauſes; and if grain, to fall down and be lodged ſo early in the ſeaſon as to render them of little value.

It has likewiſe been remarked by the writer of the Eaſt Lothian Agricultural Report, that there, within theſe few years, conſiderable tracts of this kind of ſoil, formerly of little value, have been brought under the plough, and made to produce excellent crops of turnips, clover, barley, rye, &c. as may be ſeen in different parts of the Survey; but the moſt valuable improvement upon this deſcription of ſoil has been made by laying it into graſs, and treating it with top-dreſſings of different kinds of ſoils, which, when liberally applied, have, in not a few inſtances, changed the appearance, and ſo much altered its nature, as to render it capable of bearing a ſucceſſion of valuable crops of grain.

Some think lime the beſt of all dreſſings for ſandy lands. This is the caſe, in particular inſtances, in the county of Oxford. On the fine red ſandy ſoils there, ſome lay from ten to twenty quarters on the acre; the former quantity very common in mixture with earth and ſome dung. The benefit thus produced is generally great, laſting many years.

Beſides theſe, vaſt improvements have been made in a variety of other caſes on theſe ſoils, by the uſe of the above methods. Their textures, compoſitions, and properties, have been ſo amended and improved, as to make them capable of producing crops of moſt ſorts with advantage.

6. *Peaty or Moſſy Soils.*—Theſe kinds of ſoils are more common in the northern diſtricts and in Ireland, than in the ſouthern parts of the kingdom, though in theſe latter they occur in a ſmall extent. And they, like other ſorts of ſoils, vary from the nature and proportions of the ingredients of which they are compoſed. It has been obſerved, that where the vegetable or peaty material predominates but little over the other ſubſtances with which it is mixed and incorporated, the lighter ſorts of peaty or moſſy ſoils are formed; but where the other matters bear only a ſlight proportion to it, the deep and heavy peaty or moſſy ſoils preſent themſelves. In different diſtricts the peaty matter is found of different depths, and of various degrees of denſity or cloſeneſs of texture, probably proceeding from ſome original differences in the vegetable ſubſtances from which it was formed, or the greater advances which it has made to the ſtate of perfect decompoſition. The ſub-ſoil

in moſt of the deep moſſy diſtricts is of the clayey kind, more or leſs ſtiff and heavy, over which the peaty or moſſy material is depoſited generally in a ſort of ſtratified order; the firſt layer of which, being commonly not more than ten or twelve inches in thickneſs, exhibits the appearance of a richiſh brown earth, ariſing, in all probability, from the incorporation of the loamy or clayey matters with the peat or vegetable earth lying immediately upon them, and conſtituting originally, perhaps, the ſurface of the ground. The layer that ſucceeds to this is moſtly of a dark colour, and of conſiderable thickneſs, apparently formed of a great variety of vegetable and other materials in the more perfect ſtages of reſolution or decay, united together by time and other circumſtances, with more or leſs degrees of compactneſs and ſolidity. The uppermoſt ſtratum, or that which is placed upon this denſe peaty matter, is, in general, of a very pale colour, and very light ſpongy texture, ariſing poſſibly from the graſſes, leaves, and other vegetable ſubſtances of which it is formed, not having attained that ſtate of decay which conſtitutes the darker ſorts of peaty earth. However, in the more ſuperficial peaty ſoils, little or nothing of this ſtratified appearance is met with. A coat of peaty earth, differing greatly in thickneſs, according to the peculiarity of the ſituations, and other circumſtances, is formed by a great length of time from the deſtruction and decay of ſucceſſive crops of graſſes, leaves, and other ſubſtances of different kinds, and depoſited upon, and intermixed with, the various harder materials of the ſoils which happened to be underneath them. It is obſerved, that by theſe means much variety is produced in the ſoils. Where the under ſtrata of earthy matter are tolerably good, and the crops of vegetables large and luxuriant, the better ſorts of light peaty ſoils ſeem to be predominant; but where the quality of the under ſtrata is indifferent, and the vegetable products ſcanty, as well as feeble in their growth, the poorer ſorts of theſe ſoils are formed. And in many diſtricts, this, as well as the ſandy ſoil, being depoſited or ſuperinduced, the bottom being uniformly the ſame as that of the adjoining grounds, in the low flat parts, owes its origin evidently to the ſtagnation of water; in theſe places the moſs conſiſts of the roots and decayed leaves of aquatic plants, which are found in diſtinct ſtrata, and of different kinds, according to their depth. But in ſituations more elevated, and upon the tops of the higheſt hills, the moſs has been formed in ſome caſes merely by the decay of the plants, which, falling down yearly without being entirely rotted, have, in proceſs of time, accumulated and formed the moſs there met with; but in the hollows, its formation is owing to the ſame depoſition, with the addition of a great proportion of earth, waſhed from the ſides of the hills during the floods. In ſome parts of the county of Eaſt Lothian, this ſoil has made conſiderable progreſs towards decay, and nearly reſembles black rich loam; but in by far the greateſt part, the roots and leaves of the different plants concerned in its formation are in a tolerably perfect ſtate, and when freed from moiſture, preſent little elſe than a collection of theſe.

Mr. Somerville concludes, from his experiments made upon moſs in all the different ſtages of decay, that the predominant principle in the whole is an acid; and, according as the moſs is more or leſs decayed, the prevalence of this principle is more or leſs obſervable. In the experiments upon moſs not much decayed, the quantity of acid was greater, and that of the oil and the alkali leſs, than in any of the other trials; on the contrary, where it was moſt decayed, it was found to contain the leaſt acid and the greateſt proportion of oil and alkaline ſalts. A knowledge of theſe circumſtances is of conſiderable importance in agriculture, for, by obſerving the progreſs that moſs has made towards decay, a tolerable idea can be formed of the trouble and expence that will be neceſſary either to bring it into cultivation, or render it uſeful as a manure.

And it is ſuggeſted, that from the ſame experiments it would appear, that the conſtituent parts of moſs are, 1, an acid; 2, an alkali; 3, oil; 4, vegetable earth; 5, iron. The iron was met with in one inſtance only, and in that the quantity of acid was greater than in any of the other trials; the nature of the acid was alſo different, being evidently vitriolic, a thing ſeldom met with, unleſs in caſes where the moſs contains iron, which is certainly the worſt of all its principles, and the moſt difficult to correct. And it is added, that upon comparing the conſtituent parts of moſs with thoſe of the beſt ſoils, they are found nearly the ſame, with the exception of the acid, but in ſome different proportions. The alkaline principle in ſome kinds of moſs is ſcarcely equal to what is met with in good loam or clay, while the oil and vegetable earth are much greater; a great proportion of other ſoils conſiſts of ſand, gravel, earth, &c.; but the earthy part of moſs conſiſts entirely of a mould formed by the earthy part of decayed vegetables, together with the ſediment of water.

From their compoſition, theſe ſoils muſt of courſe be extremely retentive of moiſture. It has, indeed, been remarked by the earl of Dundonald, that from the rays of the ſun and drying winds being exerted during the ſummer ſeaſon in carrying off, by means of evaporation, the ſuperabundant moiſture in ſuch caſes; and heat being known to be abſtracted from bodies, and cold generated thereby, effects muſt be produced highly injurious not only to climate but to vegetation in general, and more particularly to ſuch plants as ſtand in need of a higher degree of heat, and more nouriſhment than ſuch ſoils are capable of ſupplying. And further, that there can be very little doubt but that theſe prejudicial effects on the growth of vegetables extend themſelves to the more dry lands adjoining ſuch fens or deep moſſes. It has alſo been found, that the ſurface-ſtratum of peaty ſoils, from its being more expoſed to the influence and action of the pure air of the atmoſphere, is much leſs ſoluble than the under ſtrata, conſequently in its ſimple or unmixed ſtate leſs proper for the purpoſes of agriculture. From the ſame cauſe, too, it becomes leſs capable of ſupporting flame, and is therefore improper for the purpoſes of fuel, in the way of turf or peat.

The different manners in which moſſy or peaty ſoils are formed, have been ſeen and explained, in ſome meaſure, above, and in ſpeaking of the nature and means of cultivating moſſy lands. See Mossy *Land.*

Very extenſive improvements, in ſoils of this kind, have lately been made in Lancaſhire and different counties in the northern parts of the kingdom, as well as in ſeveral diſtricts in Ireland. See Turfy *Land.*

It may be remarked, that theſe ſorts of ſoils ſtand in need of different methods of management in bringing them to the condition of producing crops. In thoſe of the deeper kinds, the firſt thing to be done is to draw off, as much as poſſible, the ſuperabundant moiſture, by the cutting of proper drains, and ſuch other means as the nature of the ſituation, and other circumſtances, will admit of. It has been noticed, that in places where water in ſufficient quantity can be conveniently made to paſs through ſuch moſſes, and where the ſoil underneath is good, much may be effected by floating away the principal part of the moſſy ſubſtance; but where the moſſes are not deep, or the ſoils under them of a good quality, after the making of proper drains, the beſt way is, probably, to ridge them in ſuch directions and modes as are the moſt effectual in promoting the exit or paſſage of the ſtagnant water which they contain. Different materials may then be applied with the intention of improving their textures, and promoting the diſſolution of the undecayed parts of the vegetable matters that are contained in them. The firſt may be accompliſhed by the application of various gravelly ſubſtances, ſand and coarſe earth; and the latter, eſpecially where there is a large growth of coarſe plants, by the uſe of lime in its cauſtic ſtate; but where ſuch plants do not ſo much abound, alkaline ſubſtances, chalk, calcareous marle, the ſhelly kinds of ſea-ſand, and the carbonate of lime, may be more advantageouſly made uſe of. And as ſhell-marle, chalky ſubſtances, rich clays, and limeſtone gravels, are frequently met with under deep peat moſſes, they ſhould be tried for by boring in various parts. Paring and burning is alſo uſeful where the quantity of vegetable matters on the ſurface is conſiderable, and of the coarſe kind; but the method of applying good earthy matter is to be preferred where it can be procured in an eaſy and cheap manner. And advantages may be gained in promoting the fertility of theſe ſoils by cropping with particular ſorts of vegetables, as ſuch as have large branching ſtems, and cover the ſurface of the ground very much, ſo as to exclude the action of the air in a great meaſure upon it.

It is probable, too, that the hot limes, as they are called by farmers, may be laid upon theſe ſoils in full proportions with very great advantage in ſome caſes; and that where lands of any kind have been hurt by the too great uſe and abundance of them, peat will prove a good means of reſtoring them.

In theſe different ways very great improvements have been made in peaty and moſſy ſoils, eſpecially where the drains have been formed ſufficiently near to each other, and to proper depths for taking away the water in an effectual manner. Great advantage has alſo been derived by laying the ſurfaces of ſuch lands over with any ſort of heavy earthy matters to the thickneſs of three or four inches, ſuch, for inſtance, as the heavy ſorts of marle, the ſcrapings of roads, the heavy mud of rivers and ponds, &c. By theſe means, where they are intended for graſs, a finer kind of herbage is brought up, and where for the purpoſes of tillage, the ſurface is well conſolidated, and rendered more ſuitable to the growth of crops of that ſort.

7. *Boggy Soils.*—Theſe are alſo ſoils that have much of the nature of the preceding, but which differ in ſome reſpects from them, being chiefly in low confined ſituations, and of leſs depth than the heavier moſſy ſoils, and of more than thoſe of the lighter deſcription of that ſort of ſoil. There are ſoils of this deſcription frequently met with in Ireland, and occaſionally in low meadows and near large ponds or lakes in this country. Theſe ſoils are gradually formed by the depoſition and decay of the different vegetables that grow in ſuch ſituations as thoſe of the luxuriant aquatic kinds; and the ſtagnation of much moiſture upon them, by which the roots alſo become deſtroyed and reduced to the ſtate of earth. They have of courſe different appearances or colours, according to the ſtate of putrefaction and decay to which the different parts have advanced, and the nature of the other earthy materials with which they are blended; in ſome caſes being of a lightiſh brown aſpect, as where the fibrous and ligneous matters have only undergone a ſlight change; but where this has been carried to a conſiderable extent, they are of a dark colour, approaching to black, or of a deep duſky hue. See PEATY and MOSSY *Land.*

As the great defects in ſoils of this nature are chiefly thoſe of their being too much charged with moiſture, and of too open and porous a texture, the means of bringing them into a proper condition are obvious. In deep boggy ſoils, the buſineſs of draining ſhould firſt, when practicable, be reſorted to, in order to draw off the exceſſive moiſture. After which, various hard dry earths will be found of great uſe in improving bogs, ſuch as gravel, chalk, ſtony matters, ſand, ſhell-marle, &c. as theſe ſubſtances contribute to bind, ameliorate, and warm the ſoil, while they prevent ſprings from oozing out and overflowing the ſurface. Where they are over-run with ruſhes and ſimilar coarſe vegetables, quicklime may be beneficially applied, and paring and burning may be employed, ſometimes with advantage. And another uſeful mode of reclaiming ſuch ſoils is, by planting on them thoſe vegetables whoſe ſpreading roots ſerve to bind the earth together, and at the ſame time, in a great meaſure, exclude the action of the atmoſphere upon it. The practice of flooding, alſo, where a command of water can be obtained, has proved a cheap and efficacious mode of reclaiming them in ſome inſtances. Some caſes, at leaſt, have occurred where ſuch ſoils have been brought into a ſtate of cultivation for *meadows*, with the happieſt ſucceſs, by it, which had failed under contrary methods of management.

In moſt of theſe caſes, the firſt means which are neceſſary, after well ditching and draining the ſoils or lands, and levelling the imperfections and inequalities on their ſurfaces, is to apply earthy matters over them. For this purpoſe, the lumpy earthy parts, or elevations on them, are to be pared off and intimately blended up with lime into compoſts, which, with other heavy materials of proper earthy kinds, are to be placed and ſpread out on the lands or ſoils in an even manner. And afterwards, when the ground or ſoil becomes firm and ſolid, with much coarſe plants and herbage riſing upon it, eating it conſtantly cloſe down with light neat cattle and ſheep, will be very beneficial, eſpecially where ſuch ſoils or grounds are deſigned for paſtures. When for tillage, there are various other means which may be had recourſe to in different circumſtances, for rendering them more firm and dry, with great ſucceſs. See SWAMPY *Land.*

The management of ſuch ſoils, in all theſe different methods, has been productive of great benefit in different inſtances, and the land, when improved, is commonly of the moſt valuable kind. See BOG, and SPRING-*Draining.*

8. *Heathy or Moory Soils.*—Theſe form a claſs of ſoils that occupy very extenſive tracts in different diſtricts of the kingdom, and which have conſiderable relation to thoſe of the peaty ſort, though they differ in many particulars. In the ſouthern part of the country they are moſtly known under the titles of *heathy* or *moory* ſoils, but in Scotland they have the name of *muir* ſoils.

It is remarked by Mr. Somerville, in the agricultural Survey juſt noticed, that theſe ſoils, like thoſe of the moſſy kinds, owe their origin evidently to the ſame cauſe, namely, the decay of the plants that formerly occupied the ſurface. This muir ſoil is of two kinds, one of which is black, ſoft, and porous, and admits moiſture in a greater degree than any other ſoil; it is at the ſame time covered with ſtones of a white colour; evidently whinſtone bleached with an acid: the parts, when examined, exhibit the appearance commonly met in turning over the aſhes formed by the burning of vegetables, where the ſkeletons of the plants and roots are ſeen naked, ſapleſs, and deſtitute of any of the uſeful properties they once contained. It is difficult to form an opinion of the cauſe of theſe appearances, or to conceive how lands that had once been covered with plants ſo ſtrong and numerous as to form a thick ſod, ſhould become ſo barren as to be totally unfit for vegetation, as the greateſt parts of theſe muirs are. Were a judgment to be formed from appearances, fire might be ſuppoſed to have been the cauſe; but as the conſumption of vegetables by that element, however great the waſte may be of a part of their uſeful principles, is always productive of more or leſs fertility, the appearances above-mentioned muſt be owing to cauſes of which no correct opinion ſeems to be at preſent entertained. This deſcription of muir is the moſt barren, and its improvement the moſt hopeleſs, of any ſoil known there, and no attempts hitherto made have either rewarded the enterprize of the undertakers, or held out inducements to others to follow their example. But there is another ſpecies of muir ſoil, which conſiſts, like that already deſcribed, of a ſtratum of vegetable ſubſtances upon the top, not of a black or burnt appearance, but reſembling the plants in a dry ſtate intermixed with earth, without having been acted upon by any thing but the weather. Theſe, when examined, are found to contain a conſiderable proportion of the properties common to all vegetables, and when properly treated, are capable of being converted into a ſoil friendly to vegetation. The ſtones upon this kind of muir are of the ſame colour with thoſe met with upon the beſt ſoils. There are conſiderable tracts of this ſoil, which, by good management, might be conſiderably improved: indeed a great part has been much ameliorated of late years, in many diſtricts, and is in a progreſſive ſtate of improvement.

And in the analyſis of the ſame writer of the turf of theſe ſoils in the diſtrict noticed above, he diſcovered nearly the ſame principles as are found in thoſe of the moſſy kind.

No gypſum was obtained from this turf, nor did the trial by the magnet diſcover any iron. Many other trials were made with different kinds of turf, taken principally from muiriſh ſoils, the reſult of which ſeems to eſtabliſh the conſtituent parts of the turf to be, 1, an acid; 2, an alkali; 3, oil; and 4, vegetable earth, in a conſiderable quantity. In caſes where the turf is pared very thin, it is found to contain leſs acid and more alkaline ſalts and vegetable earth than where it is deep cut, and much of the ſoil taken along with it.

In the improvement of theſe kinds of ſoils different methods muſt be purſued, according as they poſſeſs more or leſs of the vegetable principle, and as they are of the deeper or thinner kinds. Where there is much heath, the great object will however be that of deſtroying it as quickly as poſſible, in which view paring and burning may be had recourſe to with vaſt advantage and ſucceſs. The application of cauſtic lime has likewiſe been found highly beneficial in the ſame intention.

The uſe of different ſubſtances of the animal and vegetable kinds, as dung and the mud of ponds, in the form of earthy compoſts, may likewiſe be found advantageous on ſoils of this nature, with judicious modes of cropping with plants of the grain and green kind; the latter being fed off as much as poſſible upon the land by ſheep.

Some think the beſt means of improving all ſorts of ſoil of this nature, is, after the heath has been, in ſome meaſure, removed, where it is long, by the application of lime or marle over the ſurface, allowing it to continue in that ſtate for the ſpace of two or three years, when theſe ſoils are to be broken up and ſown with proper ſorts of crops in alternation with turnips and potatoes, the ground being laid down again to graſs when it has been brought into proper condition for it. The turnips, where it is practicable, ſhould always be eaten off upon the ground. Where the heath is of the long ſtrong kind, it may be deſtroyed either by burning, pulling it up by the roots, or by ſuffering the graſs to riſe and choak it up. See WASTE-*Land*.

All theſe and ſome other modes may be practiſed in improving heathy ſoils with much ſucceſs in different caſes.

It therefore appears, from the whole of what has been ſaid upon ſoils, that great care and attention are always requiſite in improving the nature and qualities of them, and that the farmer ſhould conſtantly be properly on his guard in undertaking ſuch ſorts of work.

SOIL, in *Gardening*, the fine ſurface-mould or earthy materials, in which plants and trees grow and afford their produce. Different ſorts or qualities of ſoils are neceſſary, in this point of view, for different uſes and applications; but for the more general purpoſes of culinary gardening, thoſe of the more light and dry loamy kinds, which are readily broken down and reduced in their particles, are probably the moſt extenſively uſeful and beneficial, particularly when they have been well impregnated and enriched with proper ſorts of manure, or other ſimilar matters. See COMPOST and MANURE.

Some, however, think that the beſt general ſoil in this intention, is that middling kind of loam, which, in ſome parts, is capable of being made of very different degrees of lightneſs and friability, ſo as to ſuit and be proper for different ſorts of vegetable crops, by the ſimple addition of ſand or ſandy matters, in due proportions; and in other parts, of different degrees of ſtiffneſs, tenacity, and coheſion, by the ſuitable addition of clays or clayey materials, in the neceſſary quantities. There are others who prefer ſoils of very different natures and qualities, or which are very differently conſtituted, for the uſe of raiſing the many different ſorts of garden vegetables, and think it incapable of being accompliſhed in the beſt and moſt perfect manner, where this is not the caſe. It is therefore probable, that conſiderably more latitude in reſpect to the nature of ſoils is neceſſary in the garden cultivation of plants, than in that of the field.

In general, the depth of a garden-ſoil, where the bottom or ſub-ſoil is perfectly open and dry, ſhould be conſiderable, as not leſs than three feet, or more, in any caſe where ſuch a depth is to be procured; but where there is a bottom or ſub-ſoil of rather moiſt clay, or any other impervious material of that nature, a leſs depth may ſometimes be more ſuitable and proper, and particularly where ſuch bottom or ſub-ſoil has been well drained and freed from too much wetneſs: however, in all or moſt inſtances where this is incapable of being properly effected, or the trouble and expence of getting and providing a ſtratum or layer of gravel, or other ſimilar ſubſtance, to be placed over it, are too great to be incurred, the depth of the ſoil ſhould not by any means be leſs than four feet, as when it is of leſs thickneſs, there may be danger of the roots of herbaceous vegetables, and of fruit and other trees, reaching and ſtriking into it, and being thereby greatly injured or deſtroyed. And for ſome purpoſes, as thoſe of growing particular kinds of fruit-trees, ſuch a ſoil would be quite ruinous and wholly improper, unleſs ſome ſort of impediment was given to the roots ſtriking downwards, by forming a kind of pavement with ſtones, bricks, or tiles, about two and a half or three feet under the ſurface of the ground, juſt above the clayey bed. The depth of good garden ſoils ſhould, of courſe, in common, be from two to three feet, and in particular caſes four feet or more. The nature of the particular ſoils, and the ſub-ſoils or bottoms on which they reſt, muſt, however, in a great meaſure, regulate their depths.

In caſes where the natural ſoils of gardens are to be removed, and thoſe of new and better kinds formed and provided, much regard is neceſſary to be had, in the introduction of the different kinds of earthy materials of which they are to be compoſed. The ſoils of all the different parts are modes as are the moſt effectual in promoting the exit or paſſage of the ſtagnant water which they contain. Different materials may then be applied with the intention of improving their textures, and promoting the diſſolution of the undecayed parts of the vegetable matters that are contained in them. The firſt may be accompliſhed by the application of various gravelly ſubſtances, ſand and coarſe earth; and the latter, eſpecially where there is a large growth of coarſe plants, by the uſe of lime in its cauſtic ſtate; but where ſuch plants do not ſo much abound, alkaline ſubſtances, chalk, calcareous marle, the ſhelly kinds of ſea-ſand, and the carbonate of lime, may be more advantageouſly made uſe of. And as ſhell-marle, chalky ſubſtances, rich clays, and limeſtone gravels, are frequently met with under deep peat moſſes, they ſhould be tried for by boring in various parts. Paring and burning is alſo uſeful where the quantity of vegetable matters on the ſurface is conſiderable, and of the coarſe kind; but the method of applying good earthy matter is to be preferred where it can be procured in an eaſy and cheap manner. And advantages may be gained in promoting the fertility of theſe ſoils by cropping with particular ſorts of vegetables, as ſuch as have large branching ſtems, and cover the ſurface of the ground very much, ſo as to exclude the action of the air in a great meaſure upon it.

It is probable, too, that the hot limes, as they are called by farmers, may be laid upon theſe ſoils in full proportions with very great advantage in ſome caſes; and that where lands of any kind have been hurt by the too great uſe and abundance of them, peat will prove a good means of reſtoring them.

In theſe different ways very great improvements have been made in peaty and moſſy ſoils, eſpecially where the drains have been formed ſufficiently near to each other, and to proper depths for taking away the water in an effectual manner. Great advantage has alſo been derived by laying the ſurfaces of ſuch lands over with any ſort of heavy earthy matters to the thickneſs of three or four inches, ſuch, for inſtance, as the heavy ſorts of marle, the ſcrapings of roads, the heavy mud of rivers and ponds, &c. By theſe means, where they are intended for graſs, a finer kind of herbage is brought up, and where for the purpoſes of tillage, the ſurface is well conſolidated, and rendered more ſuitable to the growth of crops of that ſort.

7. *Boggy Soils.*—Theſe are alſo ſoils that have much of the nature of the preceding, but which differ in ſome reſpects from them, being chiefly in low confined ſituations, and of leſs depth than the heavier moſſy ſoils, and of more than thoſe of the lighter deſcription of that ſort of ſoil. There are ſoils of this deſcription frequently met with in Ireland, and occaſionally in low meadows and near large ponds or lakes in this country. Theſe ſoils are gradually formed by the depoſition and decay of the different vegetables that grow in ſuch ſituations as thoſe of the luxuriant aquatic kinds; and the ſtagnation of much moiſture upon them, by which the roots alſo become deſtroyed and reduced to the ſtate of earth. They have of courſe different appearances or colours, according to the ſtate of putrefaction and decay to which the different parts have advanced, and the nature of the other earthy materials with which they are blended; in ſome caſes being of a lightiſh brown aſpect, as where the fibrous and ligneous matters have only undergone a ſlight change; but where this has been carried to a conſiderable extent, they are of a dark colour, approaching to black, or of a deep duſky hue. See Peaty and Mossy *Land.*

As the great defects in ſoils of this nature are chiefly thoſe of their being too much charged with moiſture, and of too open and porous a texture, the means of bringing them into a proper condition are obvious. In deep boggy ſoils, the buſineſs of draining ſhould firſt, when practicable, be reſorted to, in order to draw off the exceſſive moiſture. After which, various hard dry earths will be found of great uſe in improving bogs, ſuch as gravel, chalk, ſtony matters, ſand, ſhell-marle, &c. as theſe ſubſtances contribute to bind, ameliorate, and warm the ſoil, while they prevent ſprings from oozing out and overflowing the ſurface. And another uſeful mode of reclaiming ſuch ſoils is, by planting on them thoſe vegetables whoſe ſpreading roots ſerve to bind the earth together, and at the ſame time, in a great meaſure, exclude the action of the atmoſphere upon it. The practice of flooding, alſo, where a command of water can be obtained, has proved a cheap and efficacious mode of reclaiming them in ſome inſtances. Some caſes, at leaſt, have occurred where ſuch ſoils have been brought into a ſtate of cultivation for *meadows*, with the happieſt ſucceſs, by it, which had failed under contrary methods of management.

In moſt of theſe caſes, the firſt means which are neceſſary, after well ditching and draining the ſoils or lands, and levelling the imperfections and inequalities on their ſurfaces, is to apply earthy matters over them. For this purpoſe, the lumpy earthy parts, or elevations on them, are to be pared off and intimately blended up with lime into compoſts, which, with other heavy materials of proper earthy kinds, are to be placed and ſpread out on the lands or ſoils in an even manner. And afterwards, when the ground or ſoil becomes firm and ſolid, with much coarſe plants and herbage riſing upon it, eating it conſtantly cloſe down with light neat cattle and ſheep, will be very beneficial, eſpecially where ſuch ſoils or grounds are deſigned for paſtures. When for tillage, there are various other means which may be had recourſe to in different circumſtances, for rendering them more firm and dry, with great ſucceſs. See Swampy *Land.*

The management of ſuch ſoils, in all theſe different methods, has been productive of great benefit in different inſtances, and the land, when improved, is commonly of the moſt valuable kind. See Bog, and Spring-*Draining.*

8. *Heathy or Moory Soils.*—Theſe form a claſs of ſoils that occupy very extenſive tracts in different diſtricts of the kingdom, and which have conſiderable relation to thoſe of the peaty ſort, though they differ in many particulars. In the ſouthern part of the country they are moſtly known under the titles of *heathy* or *moory* ſoils, but in Scotland they have the name of *muir* ſoils.

It is remarked by Mr. Somerville, in the agricultural Survey juſt noticed, that theſe ſoils, like thoſe of the moſſy kinds, owe their origin evidently to the ſame cauſe, namely, the decay of the plants that formerly occupied the ſurface. This muir ſoil is of two kinds, one of which is black, ſoft, and porous, and admits moiſture in a greater degree than any other ſoil; it is at the ſame time covered with ſtones of a white colour; evidently whinſtone bleached with an acid: the parts, when examined, exhibit the appearance commonly met in turning over the aſhes formed by the burning of vegetables, where the ſkeletons of the plants and roots are ſeen naked, ſapleſs, and deſtitute of any of the uſeful properties they once contained. It is difficult to form an opinion of the cauſe of theſe appearances, or to conceive how lands that had once been covered with plants ſo ſtrong and numerous as to form a thick ſod, ſhould become ſo barren as to be totally unfit for vegetation, as the greateſt parts of theſe muirs are. Were a judgment to be formed from appearances, fire might be ſuppoſed to have been the cauſe; but as the conſumption of vegetables by that element, however great the waſte may be of a part of their uſeful principles, is always productive of more or leſs fertility, the appearances above-mentioned muſt be owing to cauſes of which no correct opinion ſeems to be at preſent entertained. This deſcription of muir is the moſt barren, and its improvement the moſt hopeleſs, of any ſoil known there, and no attempts hitherto made have either rewarded the enterprize of the undertakers, or held out inducements to others to follow their example. But there is another ſpecies of muir ſoil, which conſiſts, like that already deſcribed, of a ſtratum of vegetable ſubſtances upon the top, not of a black or burnt appearance, but reſembling the plants in a dry ſtate intermixed with earth, without having been acted upon by any thing but the weather. Theſe, when examined, are found to contain a conſiderable proportion of the properties common to all vegetables, and when properly treated, are capable of being converted into a ſoil friendly to vegetation. The ſtones upon this kind of muir are of the ſame colour with thoſe met with upon the beſt ſoils. There are conſiderable tracts of this ſoil, which, by good management, might be conſiderably improved: indeed a great part has been much ameliorated of late years, in many diſtricts, and is in a progreſſive ſtate of improvement.

And in the analyſis of the ſame writer of the turf of theſe ſoils in the diſtrict noticed above, he diſcovered nearly the ſame principles as are found in thoſe of the moſſy kind.

No gypſum was obtained from this turf, nor did the trial by the magnet diſcover any iron. Many other trials were made with different kinds of turf, taken principally from muiriſh ſoils, the reſult of which ſeems to eſtabliſh the conſtituent parts of the turf to be, 1, an acid; 2, an alkali; 3, oil; and 4, vegetable earth, in a conſiderable quantity. In caſes where the turf is pared very thin, it is found to contain leſs acid and more alkaline ſalts and vegetable earth than where it is deep cut, and much of the ſoil taken along with it.

In the improvement of theſe kinds of ſoils different methods muſt be purſued, according as they poſſeſs more or leſs of the vegetable principle, and as they are of the deeper or thinner kinds. Where there is much heath, the great object will however be that of deſtroying it as quickly as poſſible, in which view paring and burning may be had recourſe to with vaſt advantage and ſucceſs. The application of cauſtic lime has likewiſe been found highly beneficial in the ſame intention.

The uſe of different ſubſtances of the animal and vegetable kinds, as dung and the mud of ponds, in the form of earthy compoſts, may likewiſe be found advantageous on ſoils of this nature, with judicious modes of cropping with plants of the grain and green kind; the latter being fed off as much as poſſible upon the land by ſheep.

Some think the beſt means of improving all ſorts of ſoil of this nature, is, after the heath has been, in ſome meaſure, removed, where it is long, by the application of lime or marle over the ſurface, allowing it to continue in that ſtate for the ſpace of two or three years, when theſe ſoils are to be broken up and ſown with proper ſorts of crops in alternation with turnips and potatoes, the ground being laid down again to graſs when it has been brought into proper condition for it. The turnips, where it is practicable, ſhould always be eaten off upon the ground. Where the heath is of the long ſtrong kind, it may be deſtroyed either by burning, pulling it up by the roots, or by ſuffering the graſs to riſe and choak it up. See WASTE-*Land*.

All theſe and ſome other modes may be practiſed in improving heathy ſoils with much ſucceſs in different caſes.

It therefore appears, from the whole of what has been ſaid upon ſoils, that great care and attention are always requiſite in improving the nature and qualities of them, and that the farmer ſhould conſtantly be properly on his guard in undertaking ſuch ſorts of work.

SOIL, in *Gardening*, the fine ſurface-mould or earthy materials, in which plants and trees grow and afford their produce. Different ſorts or qualities of ſoils are neceſſary, in this point of view, for different uſes and applications; but for the more general purpoſes of culinary gardening, thoſe of the more light and dry loamy kinds, which are readily broken down and reduced in their particles, are probably the moſt extenſively uſeful and beneficial, particularly when they have been well impregnated and enriched with proper ſorts of manure, or other ſimilar matters. See COMPOST and MANURE.

Some, however, think that the beſt general ſoil in this intention, is that middling kind of loam, which, in ſome parts, is capable of being made of very different degrees of lightneſs and friability, ſo as to ſuit and be proper for different ſorts of vegetable crops, by the ſimple addition of ſand or ſandy matters, in due proportions; and in other parts, of different degrees of ſtiffneſs, tenacity, and coheſion, by the ſuitable addition of clays or clayey materials, in the neceſſary quantities. There are others who prefer ſoils of very different natures and qualities, or which are very differently conſtituted, for the uſe of raiſing the many different ſorts of garden vegetables, and think it incapable of being accompliſhed in the beſt and moſt perfect manner, where this is not the caſe. It is therefore probable, that conſiderably more latitude in reſpect to the nature of ſoils is neceſſary in the garden cultivation of plants, than in that of the field.

In general, the depth of a garden-ſoil, where the bottom or ſub-ſoil is perfectly open and dry, ſhould be conſiderable, as not leſs than three feet, or more, in any caſe where ſuch a depth is to be procured; but where there is a bottom or ſub-ſoil of rather moiſt clay, or any other impervious material of that nature, a leſs depth may ſometimes be more ſuitable and proper, and particularly where ſuch bottom or ſub-ſoil has been well drained and freed from too much wetneſs: however, in all or moſt inſtances where this is incapable of being properly effected, or the trouble and expence of getting and providing a ſtratum or layer of gravel, or other ſimilar ſubſtance, to be placed over it, are too great to be incurred, the depth of the ſoil ſhould not by any means be leſs than four feet, as when it is of leſs thickneſs, there may be danger of the roots of herbaceous vegetables, and of fruit and other trees, reaching and ſtriking into it, and being thereby greatly injured or deſtroyed. And for ſome purpoſes, as thoſe of growing particular kinds of fruit-trees, ſuch a ſoil would be quite ruinous and wholly improper, unleſs ſome ſort of impediment was given to the roots ſtriking downwards, by forming a kind of pavement with ſtones, bricks, or tiles, about two and a half or three feet under the ſurface of the ground, juſt above the clayey bed. The depth of good garden ſoils ſhould, of courſe, in common, be from two to three feet, and in particular caſes four feet or more. The nature of the particular ſoils, and the ſub-ſoils or bottoms on which they reſt, muſt, however, in a great meaſure, regulate their depths.

In caſes where the natural ſoils of gardens are to be removed, and thoſe of new and better kinds formed and provided, much regard is neceſſary to be had, in the introduction of the different kinds of earthy materials of which they are to be compoſed. The ſoils of all the different parts are to be formed and prepared with great attention to their ſeveral uſes and intentions; and where fruit-trees are to be grown, particular care ſhould be taken, that the borders for ſuch purpoſes be formed and made up to proper depths, with ſuitable materials, and upon proper kinds of ſubſtrata. By ſufficiently regarding theſe points, garden ſoils of proper qualities, and fit for every purpoſe, may moſtly be provided without much difficulty.

The work of forming and compoſing garden ſoils is by far the moſt cheaply, properly, and eaſily performed at firſt when the garden is laid out; as, when done at an after period, great injury and deſtruction are cauſed in different finiſhed parts, and in various other places, by defacing and cutting them up in the labour, and rendering their appearance diſguſting to the eye, though the buſineſs is ſtill capable of being accompliſhed without any very great difficulty or expence. In all caſes of this ſort, whatever depth of natural ſoil may be wanting to form the ſoils to the proper depths or thickneſſes, as ſuggeſted above, muſt be ſupplied, by conveying it into the garden from the neighbouring lands or other ſituations, where the proper kind is to be met with in ſufficient quantity; as it is rarely, or never adviſeable to raiſe and mix up any great quantity of the ſub-ſoil, or bottom part, whatever its nature, texture, or properties may be, with it. For, in many caſes, the ſoils of gardens are greatly injured, or nearly ruined, by the improper mixing of the ſub-ſoil with the ſurface-mould. Level ſpots are ſeldom ſo proper for gardens as others, as the ſoils of them have rarely a dry bottom, and the draining of them, when neceſſary, is a great deal more difficult, than where there is ſome degree of declivity. Where there is from a foot in twelve, to that of a foot in thirty or forty feet, it will commonly ſucceed pretty well; but when about one foot in twenty-five, it has the moſt happy effect in freeing the ſoil and ſub-ſoil from too much wetneſs.

It is remarked by the "Scotch Forcing and Kitchen Gardener," as a fortunate and deſirable circumſtance, that in many inſtances the different ſorts of ſoil are met with in the ſame acre or portion of ground, and that they ſhould never be wanting in the ſame garden, but that where they are naturally deficient, in this reſpect, in ſuch ſituations, recourſe muſt be had to artificial means, in the manner that has been already ſuggeſted, for providing and producing them; for the variety of vegetables which are to be cultivated in gardens require a variety of ſoils in them for their production. It would, however, be perfectly abſurd, it is ſuppoſed, to conceive, that for every particular ſort of vegetable there ſhould be a particular kind of ſoil formed and prepared. The varieties of ſoil which are abſolutely neceſſary in almoſt any garden, may, it is thought, be confined with propriety to the following,—ſtrong clayey loam,—light ſandy loam, a compoſition of one-fourth ſtrong, with three-fourths light loam, half ſtrong and half light, and one-fourth light and three-fourths ſtrong; the two firſt being obviouſly the grand or principal ſorts, and made to form and compoſe the whole of the others. Theſe, with the proper and ſuitable applications of manures to them, may, it is believed, be rendered capable of producing any of the known and commonly cultivated garden vegetables, in the higheſt ſtate of perfection.

This is probably, however, limiting them too much or too narrowly, as though the principal ſorts of culinary vegetables may be raiſed upon them in an eaſy and perfect manner, there are ſeveral kinds of plants grown in ſuch ſituations that require ſoils of other qualities to produce them in perfection, and ſome that cannot be grown at all without thoſe of quite a different nature.

Garden ſoils, in many caſes, may be greatly and cheaply improved by very ſimple means, as by the properly drawing away and diſcharging any over-degree of moiſture, where the bottom is wet, and the ſub-ſoil of a cankering ochrey quality; and by ſupplying and intimately incorporating with the ſoil, where it is of a very ſtiff obſtinate nature, ſubſtances of the ſmall gravel, pebbly, and ſhelly ſea-ſand, coal-aſh, lime-gravel, reduced brick-bat, brick-kiln aſh, mouldering-chalk, and different other ſimilar kinds. In caſes where the ſoil is of a poor ſandy, gravelly, or other quality of ſomewhat the ſame deſcription, the improvement is to be effected by ſupplying and intermixing clay, ſtrong clayey loam, ſcourings of ditches found on clayey ſub-ſoils, muddy depoſitions of ſimilar ſituations, ſcrapings of muddy roads, and other matters of the ſame kind with them, in ſuitable proportions and an even manner.

Where ſoils of the pure ſandy, ſea-ſandy, or peat-earthy kinds, are wanted, they are to be formed by the ſupply of theſe different ſorts of materials in the proper and neceſſary proportions to ſome part of the common ſoil of the garden, as the caſe may be, without their being blended or united with it. In all other caſes the buſineſs is to be accompliſhed in ſomewhat ſimilar ways.

It is a very common opinion among gardeners, that culinary vegetables may be raiſed and grown to the beſt advantage, and in the fulleſt perfection, on what is denominated *new*, or rather freſh lands or ſoil, and this is evidently proved to be the caſe in a great number of inſtances. The ſoil or ground, in conſequence of its being exhauſted, or *worn out*, as it is termed, is found incapable of producing certain kinds of vegetables of the above nature; not becauſe it is of a poor or hungry nature or quality, or that it is wholly unſuitable for the production of them, having probably, at a former period, produced them in an abundant manner, but on account of, or from the ſurface ſoil having been ſo long under ſuch crops without any ſufficient or ſuitable change. This is, however, much leſs the caſe, in open field garden grounds, than ſuch as are incloſed for the purpoſe of producing the finer ſorts of fruit and vegetables.

The inconvenience in theſe caſes is ſuppoſed to be capable of being wholly removed, or greatly relieved, by trenching the ſoil in a peculiar manner at proper periods, ſo as to have conſtantly a new or freſh ſoil for the growth of ſuch vegetables and fruits. See *Rotation of* CROPS, and TRENCHING.

The ſoils of gardens in all caſes, except where they are too light and friable, are capable of receiving much improvement, by being fully laid up in ſuch a manner as to expoſe the largeſt poſſible ſurface to the operation of the weather, whenever they are unoccupied by crops, and eſpecially during the froſty periods of winter. On all ſtiff, heavy, clayey, loamy, and cankering gravelly ſoils, the improvement by this means is very great, and ought never to be neglected. On very light ſoils of the ſandy ſort, it ſhould, however, be very cautiouſly employed. See RIDGING *up*.

The moſt ſuitable kinds of ſoil for the growth of different ſorts of fruit-trees in gardens, are very various according to their nature and habits, but they all require that they ſhould be of a ſomewhat dry quality, as will be ſeen under their different proper heads. Where fruit-trees of the apple kind are grown in ſuch ſituations, which ſhould as rarely as poſſible be the caſe, they ſucceed in the beſt manner, are the moſt healthy, and of the greateſt durability in ſoils of the brown loamy kind, which have a middling degree of conſiſtence, and a depth of a foot and a half or more, reſting on a dry, ſandy, or ſoft clayey bottom: they will, however, anſwer tolerably on any of the loamy ſorts of ſoil which lie upon dry ſubſtrata. In all ſoils which have wet retentive bottoms, they are ſoon deſtroyed. The pear ſtands in need of a ſtronger and more clayey ſoil than the above, which has much greater depth, but which reſts on the ſame ſorts of ſubſtrata. Similar ſorts of ſoil are alſo the moſt adapted to the growth of the cherry and the plum. And the ſmall fruit-trees, in ſuch caſes, may be well grown in any ſoil which is not of the ochrey or wet ſtiff clayey kind. See Small *Fruits*, and Standard *Fruit-trees*.

Soils for the purpoſe of ornamental gardening are not only of great utility in growing and rearing the different plants and trees which are neceſſary for it, but have been employed in the way of contraſt, and for relieving them. Formerly, much advantage was taken in this manner, by the introduction of different coloured earths or ſoils, but they have ſince, probably with juſtice, been reprobated as too trifling and inſignificant by lord Bacon: the natural ſoil throughout is always, Mr. Loudon thinks, preferable; and when taſtefully varied by the green of vegetation, will have a very harmonious effect in ſuch caſes.

The quality of the ſoil for the growth of moſt ſorts of ornamental plants and ſhrubs, ſhould, it is ſaid, be rather poor; for moſt of thoſe of the wild or botanical kind, various, though principally dry paſture loam of a virgin nature; but for the ericas or heath ſorts, and moſt of the American and Cape plants, as well as ſome others, moſſy or peaty, and rather moiſt.

The ſoil, in its different kinds, has much effect in improving, or *breaking*, as it is termed by the floriſts, ſome ſorts of fine flowering plants, as ſeveral of the bulbous-rooted and more tender herbaceous kinds, ſuch as tulips, pinks, carnations, and many others. The common plants of the latter deſcription will, it is believed, grow in almoſt any ſort of ſoil.

The particular ſort of ſoil in which moſt of the moſs-plants and ſhrubs commonly grow to the beſt advantage, is, it is ſuppoſed, that of a ſandy moſs or peat of a moderate degree of moiſture. The ſoils for wild plants are almoſt, it is remarked, as various as their names, but, in common, ſuch as are mentioned below, will grow moſt of them when cultivated in a garden:—dry virgin mountain earth or ſoil; moſſy earth or ſoil in a damp ſituation; half of each of the above in a moiſt ſituation; half of each in a dry poſition; moiſt clay and moſs or peat well blended; dry gravel and ſand incorporated well together; a clear ſandy or gravelly bottom ſoil, where there is a ſlight trickling of water; a muddy bottom ſoil, in a low ſtagnant pond or other water; rock-work, differently conſtructed, forms a ſoil for certain plants, as ſome moſſes, ferns, and others of the ſame ſort; living full-grown trees, as well as ſuch as are decayed, provide a ſoil for the growth of particular moſſes and funguſes; the ſoil of the ſea-ſhore is proper for the growth of ſea-plants; and the differently formed ſoils in heated houſes and other places, are ſuited to the growth of moſt ſorts of exotic plants. The two firſt ſorts, with thoſe of the trickling and ſea-ſhore kinds, will, however, it is ſuppoſed, nearly ſerve the purpoſes of all the others, when properly managed.

For the purpoſe of raiſing different ſorts of foreſt-trees, and forming ornamental plantations, great variety of ſoils is neceſſary; ſuch as thoſe of the more light ſandy and gravelly kinds, which reſt upon free, open, porous under ſoils or bottoms; ſandy and gravelly loams on the ſame ſorts of bottoms; the ſame and perfectly loamy ſoils, on bottoms which are of a more retentive or wet nature; chalky or calcareous loams, and gravelly mouldering chalks on open bottoms; loamy clays and clayey loams, on ſimilar bottoms; ſtrong ſoils of both theſe ſorts on more retentive and moiſt under ſoils; thin, peaty, heathy, and moory ſoils, which lie on gravelly and other ſorts of open dry bottoms; and ſimilar ſoils, reſting on more ſtiff and retentive ſubſtrata, or ſuch as are of a moiſter quality.

Other variations in the nature of garden-ſoils may likewiſe be occaſionally neceſſary for particular purpoſes, as well as in thoſe of grounds which are intended to be laid out and ornamented.

Soil, *Night*, in *Agriculture*, the excrementitious matter which is taken from privies or other places in which it is depoſited. Sir Humphrey Davy has remarked, that it is a well-known very powerful manure, which is extremely liable to decompoſe. That it differs in compoſition, but conſtantly abounds in ſubſtances conſtituted of carbon, hydrogen, azote, and oxygen. And that from the analyſis of Berzelius, it appears that a portion of it is always ſoluble in water; and in whatever ſtate it is employed, whether recent or fermented, it ſupplies abundance of food to plants, either as crops, or in other ways.

It is ſuggeſted, that its diſagreeable ſmell may be corrected and deſtroyed by mixing quicklime with it; and that, if expoſed to the atmoſphere in thin layers, ſtrewed over with quicklime in fine weather, it ſpeedily becomes dry, is eaſily reduced into powder, and in this ſtate may be made uſe of in the ſame way as rape-cake and other ſimilar manures, being delivered into the drill-furrows at the ſame time with the ſeed.

The refuſe of charcoal warehouſes, and the powdery matter of that ſubſtance, might alſo probably be intermixed with the calcareous and excrementitious materials in the above compoſition with great advantage.

It is ſtated that the Chineſe, who have more practical knowledge of the uſe and application of manures than any other people exiſting, mix their ſoil of this ſort with one-third its weight of a fat marle, make it into cakes, and dry it by expoſure to the ſun. Theſe cakes, as has been ſaid by the French miſſionaries, have no diſagreeable ſmell, but form a common article of commerce in the empire. It is ſuppoſed that the earth, by its abſorbent properties, probably prevents, to a certain extent, the action of moiſture upon the excrement, and likewiſe defends it from the effects of the air.

The Japaneſe, and ſome other of the eaſtern nations, are likewiſe very careful in preparing and preſerving this ſort of manure; and different methods of collecting, increaſing, and ſecuring it in this country have been noticed in ſpeaking of manure. See Manure.

It is ſuppoſed by ſome to have a great ſuperiority over all other ſorts of manure, even that of the rotten horſe-dung kind, being conſidered nearly five times as valuable as this laſt ſort. There is conſequently believed to be a great ſaving in the purchaſe of this manure, by thoſe who have the carting of their dung ſeven or eight miles, as their teams would bring as much of it in one, as would be equal to what is uſually brought of the other by them in five days: that they would have as much as is equivalent in value for one guinea, to what formerly coſt them five. And though the price of it may be on the increaſe, that ſhould not, it is thought, deter them from the purchaſe of it, as the ſaving in carriage is, it is ſaid, amply ſufficient to repay every advance in the firſt coſt of the material.

Others, however, ſuppoſe that this ſort of ſubſtance in manuring land will not go farther than three times that of common dung, in giving fertility. It is uſually ſold at 5*s.* the load. It has lately, in ſome places, been the practice to mix and work up this ſort of ſoil or excrement with mould or other earthy matters, in a regular manner, to conſiderable extent. This is largely done, it is ſaid, in the neighbourhood of the metropolis.

Upon the whole, conſidering the ſmallneſs of the quantity which is neceſſary, this may be allowed to be the moſt powerful and effectual manure of any which is now in uſe for improving land.

In the county of Eſſex, about Hornchurch, Mr. Newman has found that, for paſture, this ſort of manure is, of all others, the moſt capital; two waggon-loads on the acre, which coſt 7*s.* beſides carriage, are, it is ſaid, beyond every thing, and ſecure a carpet of fine herbage. On corn-land, however, it is thought that it forces ſtraw too much. Others have alſo found this to be the caſe, but when well mixed with good earthy ſubſtances, in ſufficiently full proportions, there can be no doubt of its being equally ſuitable for raiſing good grain crops.

On account of the increaſing ſcarcity of manure, this ſort of material ſhould be every where more attended to and preſerved than has hitherto been the caſe; and it may be largely increaſed as a manure by the addition of ſuitable quantities of earthy or other proper matters, according to circumſtances, and the purpoſes for which it is to be employed, as well as be rendered more fit and convenient for carriage and application.

SOIL, *Preparation and after-cultivation of, for and in planting*, in *Agriculture* and *Gardening*, the manner of rendering it ſuitable and proper for the reception of the trees, and of keeping and preſerving it in order afterwards.

The nature, ſituation, and ſtate of the ſoil, muſt unqueſtionably have much influence in determining and directing the degrees of preparation that may be requiſite in the different caſes; and though there may be ſome ſoils which require very little, this can but ſeldom be the caſe, as good ſoils ſhould never be planted, except for ornamental purpoſes, and then as little as poſſible. It conſequently appears proper, that ſome degree of preparation of the ſoil ſhould conſtantly take place in almoſt all caſes, however the miſtaken notion in regard to the expence attending it may have hitherto prevented the general adoption of the practice.

The expence of the proper preparation of the ſoil, before the work of planting commences, in many caſes, is not by any means great, when properly managed; and in no few inſtances, may be more than repaid by the kinds of crops that are afterwards grown for two or three years, and ſometimes longer: nay, even where ſuch crops cannot be raiſed and produced, the ſaving in plants and planting, which would otherwiſe be required, will often wholly or nearly defray the charges of the preparation. Thus, it is ſaid by Mr. Loudon, that, independently of timber produce, it would ſeem that the extra charges of preparing the ſoil may commonly be provided for in the immediately ſucceeding years to the work's being finiſhed, either poſitively by the growth of proper crops, or negatively by obviating the incurring of additional expences. And that, when the difference in the returns of timber produce are taken into the account, it may appear aſtoniſhing that the cultivators in this way ſhould diſregard their own advantage ſo much as to neglect and omit the proper preparation of the ſoil. For if it ſhould be ſuppoſed that, during the firſt ten years, trees grow only twice as faſt where the ſoil is properly prepared, as where it is not, then even a plantation worth 100*l.* in fifty years, had the ſoil been well prepared, would have been worth 200*l.* in the ſame length of time. But it muſt be allowed that many kinds of deciduous trees will grow three, four, and even ten times faſter in prepared than in unprepared ground, and, of courſe, the return of profits be in the ſame proportion.

Theſe ſtatements can ſurely leave no doubt of the propriety of preparing the ſoil with a view to theſe ſorts of undertakings.

The preparation of the ſoil will vary according to its nature, and the circumſtances of it; after the ſtagnant wetneſs, where preſent, has been properly removed, and the ſurface impediments cleared away as much as may be found neceſſary. In all ſtiff ſoils the land muſt be more wrought and expoſed than in the contrary ſorts, which often require but little ſtirring or expoſure. In extenſive tracts, the ground or ſoil, when poſſible, ſhould be prepared by means of the plough, by turning it up and expoſing it to the operation of the atmoſphere and froſts in the ſummer, autumnal, and winter months, when of the more rough and obſtinate kind, repeating the ploughings, and making harrowings as there may be occaſion. In extremely rough moory, and ſome other coarſe ſorts of ſoil, this may be neceſſary for more than one ſeaſon. After this, trench-ploughing may be had recourſe to wherever it is wanted, and is capable of being practiſed. By the uſe of the plough in theſe ways, the organic matter becomes more decompoſed, and the particles of the ſoil more fully and completely broken down and reduced, than by performing the work with the ſpade, while the coſt is not more than one-third.

In places where the plough cannot be admitted, other methods muſt be had recourſe to, as thoſe of the ſpade, the broad-mouthed mattock, and the ſharp-pointed ſtrong hoe. The ſpade muſt be employed in all caſes where digging and trenching can be practiſed, where the plough cannot work, and in forming pits, ſlits, and other modes of putting in the plants. Where the ſpade cannot be made to perform the buſineſs, the mattock not unfrequently does the work in a ready and effectual manner. And where the mattock cannot be brought into uſe, the hoe often completes the work without difficulty. The two laſt methods may be uſeful in ſteep banks and ſpots filled with ſtones and other obſtructions to the ſpade. The ſoil in all theſe caſes is to be properly reduced and rendered ſufficiently fine for the reception of the tree-plants, by being ſtirred, incorporated, and mixed together in a ſuitable manner.

Particular ſituations may require particular modes of preparing the ſoil and putting in the plants: thus, where there is danger of looſe ſoil being carried away by winter rains, the land ſhould be prepared in the previous ſummer ſeaſon, by making holes or openings, the earth of one of which is thrown into another with the turf or ſward-ſide downwards, which, when opened again for planting, is become rotten, and intermixed with the reſt of the ſoil in putting in the plant. In other ſituations, where the wind and rain are liable to carry off the ſoil, the only ſafe mode of preparing the ſoil is in pits, holes, and ſlits, and placing the plants in them. And in ſtill more difficult places, little or no preparation is neceſſary, only putting in the plants in openings or ſlits, or ſowing the ſeeds, which will often grow in rocky crevices, where little or no earthy matter is to be ſeen or met with. The nature of growth in the plants or ſeeds points out in ſome caſes the modes of preparation of the ſoil for them; thus, in the very young plants, and in ſeeds of the oak-kind, where they are only uſed, the placing them in holes or pits, prepared in a proper manner, is all that is neceſſary, as they receive the chief of their ſupport from their tap-root, which runs directly downwards.

In regard to the cultivation of the ſoil, after the work of planting the young trees has been performed, it muſt obviouſly be of great uſe and importance to keep the ſurface looſe, clean, and free from the production of all ſorts of improper plants of the weed kind, as the health, growth, and ſucceſs of ſuch tree-plants will very much depend upon it; and, beſides, it may be advantageous in other ways. In caſes where this is neglected, or improperly managed, there is often much injury ſuſtained by the young tree-plants, as they are not unfrequently liable to be more choaked up and inconvenienced in their growth by the riſing of coarſe graſſes and other productions, than if the ſoil had not been prepared previouſly to the trees being put into it. The cauſe of this is thought, by Mr. Loudon, to be extremely plain; as, if the ſoil, by preparation, be better ſuited to the growth of trees which are foreign to it, it muſt be much better adapted to the growth of the plants which it naturally produces in abundance. Conſequently, to check and remove theſe, ſo that the roots of the young tree-plants may range, and extend themſelves in a free manner, ſo as to require and enjoy the full ſtrength and ſupport of the ſoil, muſt be of very material benefit in raiſing plantations of the tree-kind.

The nature of the cultivation which is to be purſued muſt be varied ſo as to ſuit the particular quality of the ſoil, the ſituation, and the kind of plantation for which it is employed; but the great object, in all ſuch caſes, ſhould conſtantly be, to have in view utility, with as much immediate profit as poſſible, without the riſk of injury to the young tree-crops. Conſequently, wherever the ground or ſoil is capable of admitting and producing any ſort of proper uſeful vegetable, and the roots of the trees do not interfere by approaching too nearly to each other from the different rows, ſome of them ſhould be planted, or the ſeeds of them ſown in a regular manner, all along the centre parts of the intervals between ſuch rows, for ſome length of time, as a year or two, and more in ſome inſtances, after the planting has been performed. The moſt uſeful and valuable vegetable crops to be grown in this way, are thoſe of the potatoe, turnip, cabbage, dwarf bean, and ſome other ſimilar ones of the green kind. The introduction of ſuch crops neceſſarily ſuppoſes that the whole of ſuch planted grounds are to be wrought over, and kept in a clean order by ſome proper means, during the lengths of time that have been ſtated; after which they need only be hoed over two or three times in the courſe of the year, until the ſurfaces of them be covered and concealed by the trees, which they will moſtly be about the fourth or fifth year from the period of planting. All the work of the above kind, where the ſcale of planting is extenſive, may be executed by means of the plough and horſe-hoe; except occaſionally, perhaps, ſome little hand-hoeing about the bottom ſtems of the tree-plants, where there might be danger in letting the other tools work too near them. Where, from different circumſtances, it may be impoſſible to introduce the plough, the ſpade and hand-hoe muſt, of courſe, be had recourſe to in working the ſoil. But wherever the ſoil is incapable of admitting and producing uſeful vegetables, or where it may be thought not adviſeable to grow and cultivate them, the ground or ſoil may perhaps be the moſt properly and advantageouſly preſerved in clean order, ſimply by hoeing over the ſurface; or ſometimes probably by light ploughing or working with the ſpade, for a year or two at firſt, and then to depend on hoeing. The chief point in all caſes is the promoting the progreſs of the young trees, and the preventing them from being injured by the ſtiffneſs, rawneſs, and want of cleanneſs in the ſoil.

Whenever the ſurface of the ground or ſoil is covered by the young trees, there is no longer any neceſſity for cultivation, it being from that time preſerved in a ſufficient looſe and open ſtate, and the ſurface properly free from weedy matters, by the cloſeneſs and ſhade of the trees, and the annual falling of the leaves; and particularly where the planting conſiſts of reſinous trees. It is noticed, too, by the above writer, that it is the peculiar property of deciduous plantations, that the ſurface among them is covered with herbage of the paſture kind, the ſeeds of which ſhould be ſown when the trees are about nine inches or a foot in diameter, they having been well preſerved from weeds previouſly to the period of ſowing. See PLANTATION and PLANTING.

It is not improbable, but that when the buſineſs of preparing and cultivating the ſoil for plantations becomes better underſtood, and its uſes and advantages more fully appreciated, more ſuitable implements, tools, and contrivances may be provided for accompliſhing the work in a more eaſy, ready, cheap, and convenient manner, than has yet been employed.

SOILS, *Cutting Surface of*, the opening and breaking the ſurfaces of them in different intentions; as for the purpoſe of rendering them more dry and firm, of producing a more mellow, mouldy, or powdery ſtate in them, and for improving the nature of their ſwards and graſſy herbage in thoſe of the moſſy, rough, mowing, and paſture kinds. It may likewiſe be uſeful to them for ſome other purpoſes in huſbandry. It is performed in different manners, and by different means, according to the circumſtances of the different caſes, and the uſes which it is deſigned to ſerve. See SPIKE *Roller*, and SWARD *Cutter and Dreſſer*.

SOIL, in *Zoology*, is uſed in ſome parts of England as the name for the *phoca*, or *ſea-calf*.

This creature, in Cornwall, they frequently find ſleeping on the ſhore, and kill him, ſometimes by ſhooting, and ſometimes by ſtriking him over the head with long poles. He defends himſelf, when on ſhore, by throwing ſtones backwards with great violence.

SOILING, in *Agriculture*, the practice of ſupporting animals of different kinds, in the ſummer ſeaſon, with green food of various ſorts, cut daily, and given to them in racks in the houſes, ſtalls, or yards. A vaſt number of different plants and graſſes may be had recourſe to in this intention, as almoſt all thoſe which have a quick and luxuriant growth; as lucern, tares, clover, ſaintfoin, chicory, &c. And it has been ſuggeſted, that by having recourſe to ſoiling, a greater variety of plants may be conſumed, and conſequently prevented from running to waſte. Alſo, that if the conſumption of plants be an object principally regarded, it is obvious that the benefits thence derived will be very great, as experience has clearly proved that cattle will eat with avidity many plants, if cut and given to them in the houſe, which they never will touch while growing in the field; ſuch are the dock, cow-parſley, thiſtles, nettles, and numerous other plants. But to whatever circumſtance this may be attributed, the fact is, that the animals will eat them without exhibiting any marks of diſlike or reluctance, even when they are not preſſed by hunger, and they often greedily devour ſuch plants, as ſoon as they are brought in from the field, and before they can have poſſibly had time to become hungry. There are even vegetables, which, in a green ſtate, are poiſonous to cattle; but which, when cut and dried into hay or fodder, may not only be given with impunity, but are alſo eaten with avidity. Such as the water-crowfoot, with which, Dr. Pulteney ſays, the cottagers in the vicinity of Ringwood, on the banks of the Avon, almoſt entirely ſupport their cattle; and ſo eagerly do theſe animals conſume it, that they deem it unſafe to allow them more than a certain quantity. Cows indeed are aſſerted to be ſo peculiarly fond of this vegetable (which keeps them in good milking condition), that, excluſive of the ſcanty pittance which they obtained on an adjacent heath, *five* cows and one horſe did not conſume more than half a ton of hay in the courſe of a year. Thus it is evident, that fewer plants will either be rejected, or ſuffered to run up to waſte. And that it is further well known that many of the beſt and fineſt graſſes, which, when young, form a moſt palatable food to cattle, are, if once ſuffered to get into ear, ſo much diſliked by them, that the beaſts will never taſte them unleſs compelled by extreme hunger. And, as in moſt paſtures many of theſe graſſes get into ear from various cauſes, their produce is of courſe inevitably loſt to the farmer; whereas, if cut down by the ſcythe in proper time, not one plant will be ſuffered to get into that nauſeating ſtate, and conſequently no waſte be ſuſtained on this account. Alſo, that, in addition, thoſe few plants which are totally diſregarded by one claſs of animals, ſo as to be rejected by them even in the houſe, will not, on that account, become leſs acceptable to others, but greatly the reverſe. Thus graſs, or other food that has been *blown* or *breathed upon* by any animal for a conſiderable time, becomes unpleaſant to other beaſts of the ſame ſpecies, but not ſo to ſtock of another claſs or variety, as for them it appears to acquire a higher reliſh. Even greater defilement by one animal ſeems to render food more acceptable to others; for ſtraw, which in a clean ſtate has been refuſed by cattle, if employed as a litter for horſes, acquires for the former ſuch a reliſh, that they ſeek for it with avidity. Hence it happens, that the ſweepings of the ſtalls from one animal ſupply a pleaſing repaſt for thoſe of another kind, which can be eaſily removed from one to the other, if the plants are conſumed in the houſe, but which muſt otherwiſe have been loſt in the field.

This is a practice which is alſo recommended by the food being conſumed with much leſs waſte, conſequently going much further than when fed upon the land; by the great increaſe of good manure that is produced; and by that of the ſtock feeding with leſs interruption and inconvenience, from their being more effectually ſhaded from the exceſſive heat of the ſun, and better protected from the attacks of flies and other inſects. In all theſe reſpects it would ſeem to have a great ſuperiority over that of letting the animals range over the paſtures or other graſs lands. One great and principal objection that has been oppoſed to this plan of feeding, is that of the expence of conducting the buſineſs being too conſiderable. But the extenſive trials of Mr. Mure and Young, and other cultivators and promoters of the practice, fully ſhew that it may be executed at an expence that can never form any real objection to it. It has likewiſe been contended, in oppoſition to this practice, that ſuch parts of the live-ſtock as are in milk do not afford it ſo abundantly as when fed in the paſtures, but which is probably a mere ſuppoſition, as it has been almoſt invariably found that moſt of the green crops that are cut and employed in this manner have greater effect in exciting that ſecretion than the common paſture-graſs. But as particular ſorts of vegetables, as well as other ſubſtances, act more powerfully on ſome of the glandular organs than others, it is probable that ſome kinds of plants may have a greater tendency to promote this kind of ſecretion than others, and on this account, cows fed on one ſort of food in this practice may afford leſs milk than on others.

Farther, it is a proceſs of feeding that has alſo been oppoſed, on the idea that animals do not thrive ſo well as when grazed in the paſtures. It is, however, well remarked, that the more quiet and free from diſturbance cattle are kept, the better they thrive and improve in their fleſh. It is not probable that green food, when properly conſumed in the ſheds of a farm-yard, will be leſs advantageous in promoting the growth and fattening of ſtock, than when eaten in the field, when expoſed to the great heat and conſtant attacks of flies, and of courſe kept in a continual ſtate of reſtleſſneſs and inquietude. Beſides, in experiments to which we might refer, the cattle were found to go on better than ſtock of the ſame kind, fed in the paſtures in the moſt favourable ſeaſons for the purpoſe. And this is further ſupported by trials carefully made, and detailed in the Annals of Agriculture. This notion does not, therefore, appear well ſupported by facts, or to have had any foundation in the experience of farmers in general.

But its ſuperiority in reſpect to the economical conſumption of the food cannot be diſputed. In numerous experiments made in proof of the great ſaving in this way, it has been found to go from twice to four or five times as far as when fed on the land; and in ſome trials, much more. Mr. Cloſe found that with graſs, clover, lucern, and tares, three times as many cattle were capable of being ſupported in better condition than in the paſture mode of feeding; and with other experimenters it has been found equal to five or ſix times as many. The author of a late work has remarked, that in the field it is obvious that great waſte muſt be committed by the graſs being trampled down, dunged upon, and in many other ways, eſpecially where a great number of cattle are paſtured together, moſt of which are avoided in the ſtall method.

It has been, however, ſtated, that it is an error to ſuppoſe that all the waſte is in feeding in the field, and none in the ſtall: there is, on the contrary, a waſte in ſoiling; as in caſes where the tares become podded, from the butt ends of the plants being coarſe, and in a ſtate of decay by lying on the ground, and, of courſe, rejected by the animals. The ſame thing alſo occurs with lucern, when in full bloſſom. Alſo, in the heating of the food, by its remaining heaped together, loſs may likewiſe be ſuſtained in ſome inſtances; but it ſhould moſtly be conſumed quite freſh in this practice, and no more cut than is neceſſary for the day.

However, whatever the waſte in theſe different ways may be, various trials detailed in the Annals of Agriculture clearly prove, that a greatly increaſed ſtock may be kept upon the ſame extent of land in the ſoiling method, over that of the grazing of the cattle in the fields where the plants grow.

But the moſt intereſting circumſtance in which this practice excels that of paſture feeding is, however, in the immenſe quantity of excellent manure that is raiſed and provided for the production of increaſed crops of various kinds, and the additional improvement of the lands. It has been well remarked, that this is a method admirably calculated for producing an abundance of manure; as from the great increaſe in the urinary diſcharges, in the conſumption of green food in this way, and the heat of the ſeaſon, the littering material, whatever it may be, is ſpeedily converted into manure; by which means, with proper attention, vaſt ſtores may conſequently be raiſed, where there would otherwiſe be none; which is a circumſtance of the greateſt importance, and which abundantly ſhews the great utility and ſuperiority of the practice. By theſe means, the ſummer produce in manure may probably be made to exceed that of the winter, and at the ſame time be ſuperior in quality; as there is reaſon to ſuppoſe that the manure produced by any kind of cattle fed in the ſame way, when not in a ſtate of fattening, is much better in the ſummer than in the winter ſeaſon. The proportion of valuable manure that the careful farmer may be capable of providing, by this ſyſtem of management, is ſcarcely to be conceived, except by thoſe who have been in the actual practice of it. In this view, it is of much importance to have reſervoirs for the reception of the urine, in order that it may be occaſionally thrown up over the litter, and thereby promote its ſpeedy converſion into manure. The manure afforded by fattening animals, ſuch as hogs and neat cattle, is in all ſeaſons of a rich and valuable quality.

But in order to enſure the fulleſt benefit and advantage from this ſyſtem of management, the moſt ſtrict attention is neceſſary to different circumſtances: ſuch as thoſe of having convenient ſheds and yards for the purpoſe; providing ſuitable crops in proper ſucceſſion, to the proportion of ſtock to be kept; the feeding and managing the animals in a proper manner; and the making a full proviſion of the materials, for the purpoſe of littering down the ſtalls or farm-yards. And further, in this ſyſtem of management, much depends on the convenience of the yards and ſheds, in reſpect to the economy of labour in feeding the cattle, as well as making of manure: it is, of courſe, neceſſary to have them upon ſuch plans as may afford the greateſt advantage in theſe ways. It has been ſuggeſted by ſome, in order to ſave the labour and expence of cleaning and feeding in this ſyſtem, to have the cattle left looſe in the yards, ſo as to conſume the food from racks or cribs; the bottoms of the yards being prepared by marle, or other ſimilar materials, and a coat of litter applied, ſo as that the urine may be abſorbed, retained, and contribute to the converſion of them into manure. But a ſuperior plan is probably that of having them tied up in ſtalls, in ſheds for the purpoſe; as, although ſomething may be gained in the former mode in the labour of cleaning, the latter has conſiderable advantage in the goodneſs of the manure, and in the animals being kept more quiet, and leſs expoſed to diſturbance from inſects of different kinds. In the former of theſe modes, the ſtock ſhould be ſorted, and thoſe of the ſame age or ſize fed together.

In the experience of Mr. Cloſe, it was found advantageous to ſoil horſes in cheap thatched ſheds, in which they have room to walk and roll; and with bullocks and cows, in ſtalls ſeven feet wide, each ſtall holding two faſtened by the necks to the ſides, by which they are prevented from inconveniencing each other while feeding.

In this method of management, it is not unlikely that great benefit might be produced by having low ſheds fixed up round the yards, or other places, with ſuitable contrivances for the cattle receiving the food from, ſo as to cauſe the leaſt poſſible loſs; and by having the ſtock in all caſes properly ſorted, in regard to ſize, kind, and ſtrength. Such ſheds might, in ſome inſtances too, be provided, with very great utility and convenience, near to the grounds whence the food is raiſed and procured. In this way, a great ſaving of labour and expence would neceſſarily be made in different ſituations.

In all the caſes where low ſheds are made uſe of in this intention, there ought to be proper drains formed for conveying the urine and other fluid matters into the littered yards, and other places deſigned for forming manure, ſo that they may have a conſtant operation in the preparation of it.

It may alſo be neceſſary and beneficial, in this practice, ſometimes to have different ſets and ſorts of animals, in order that the refuſe of the food left by one ſet may be eaten by another, and no kind of loſs ſuſtained.

But in order that this buſineſs may be conducted in the moſt beneficial manner, it is neceſſary the farmer ſhould carefully attend to the culture of ſuch green crops as have been mentioned above, and which can be beſt applied in this way, on a ſcale fully ſufficient for this purpoſe. In the view of early application, a full proportion of lucern ſhould be raiſed on the moſt deep and fertile ſoils; and on the better ſorts of land, that may be in the condition of fallow, clover and tare crops may be grown. Theſe muſt be ſown ſo as to come into uſe at different times; the firſt crop of winter tares ſucceeding to the early cut lucern; the later put in winter tares following, after which the clover will moſt probably be ready, to which the third crop of tares and the ſecond cut of lucern may ſucceed: at a ſtill later period the ſpring tares may be employed; and in ſucceſſion to this, the third cutting of lucern will in general be ready. But there are many other plants that may perhaps be made uſe of in this way, as chicory, which may be had recourſe to with advantage in this management; as in ſoils that are tolerably fertile, it will admit of repeated cutting. With theſe different crops there will probably be ſeldom any neceſſity for the uſe of common cut graſs; though this may be employed, if there ſhould be occaſion. The proper foddering of the animals in this practice is a matter of great conſequence. It is obſerved in the Annals of Agriculture, that one great object is never to ſuffer them to have too much at once; as when this is the caſe, from the heat of the ſeaſon, it quickly takes on a degree of fermentation, and is rejected or only picked among by the cattle, in conſequence of which much waſte may be committed, which would otherwiſe be avoided; and in addition, it is not improbable but that the ſtock may thrive better by having their food more frequently, and of courſe in a more freſh ſtate. But it ſhould never, on any account, be left packed in the carts for any length of time. The beſt mode ſeems to be that of adapting the ſize of the cart to the exact conſumption of the ſtock; as in this way, the whole may be conveniently diſtributed in the cribs or racks at once, the moment it is wanted, before it becomes unpalatable by fermentation, and the leaſt poſſible loſs may be incurred. It is conſtantly neceſſary to watch the conduct of labourers in this particular, as they are in general much diſpoſed to over-feed. And there is another matter which ſhould not be diſregarded, which is that of not ſuffering the crops that are uſed in ſoiling to advance to too great a head; as by attention in this reſpect, the food may be more cleanly eaten up and conſumed.

However, it muſt be obſerved, a late writer ſays, that in this ſyſtem litter becomes an object of the greateſt importance, as the large quantity of urine that is made by cattle, when ſoiled on theſe luxuriant ſorts of green food, is capable, by its moiſtening property, of aiding in the hot ſeaſon, the more quick fermentation of ſuch materials, and of reducing a very large proportion into the ſtate of manure. In this view, the attentive farmer ſhould, therefore, make an abundant proviſion, in the winter time, of other ſorts of materials, where a proper ſupply of ſtraw cannot be reſerved for the purpoſe. There are various matters that may be made uſe of in this intention, ſuch as ſtubble, fern, ruſhes, and other aquatic plants, which may be cut and raked together in the places in which they are moſt abundantly produced, in order to be ſtacked up for future uſe. Leaves might alſo, in woody ſituations, be uſeful for the ſame purpoſe. And in addition to theſe vegetable matters, there are other ſubſtances that are capable of being employed with utility, ſuch as peat or bog earth, freſh vegetable mould, ſand, and the ſcrapings of roads; as during the decompoſition of the various vegetable materials made uſe of in this practice, not only much hydrogen and carbonic gas are ſet at liberty, but ammonia is formed in large quantities, in the manner that has already been explained, which, from its action upon ſuch earthy materials, is highly uſeful in bringing them into the ſtate of manure for the improvement of lands. See MANURE.

Some other ſorts of matters might likewiſe, in different ſituations, be employed in this manner with conſiderable benefit; ſuch as ſaw-duſt, when to be procured in large quantities; and the refuſe materials of different manufactories, as the weld of the callico-printer, the bark of the tanner, &c. Many of theſe kinds of ſubſtances are excellent for the purpoſe of manure.

And in ſupport of the advantages of this management, various facts have been ſtated by writers on farming. It is remarked by the Rev. Mr. Duncan, in the fourth volume of Communications, that he always keeps his work-horſes on red clover through the ſummer; and they are as healthy and fit for labour as any of his neighbours', that are turned out into the paſture. Laſt year he cut the clover three times, and thirty falls or perches yielded as much as one horſe was able to conſume. He has frequently intended to try a crop of gooſe-graſs for hay, upon ſome piece of ground which was not to remain in paſture; but he has always met with ſome avocation, at the time when the ſeed of this graſs could be procured. He is ſurpriſed that gooſe-graſs has been ſo long neglected, nay deſpiſed. It is conſidered as a weed among rye-graſs, though he has obſerved that the horſes are not of the ſame opinion. Its hay is moſt ſubſtantial, and were it allowed to come to maturity, its ſeed would, he ſuppoſes, be little inferior in weight to oats, and would probably be an excellent ſubſtitute for them in the food of horſes. And it is added, that he who can procure 200 carts of dung, from the ſame extent of ground where 100 only were formerly produced, certainly poſſeſſes a double power of improving it. A great reſerve of ſtraw is neceſſary for litter to horſes, when living on red clover. When the ſtraw fails, ſome bed their horſes with dried ruſhes; but ruſhes contribute very little to the manufacture of dung. When fern, or, as it is ſometimes called, the "braken," can be gotten, he would recommend it as next to ſtraw for littering of horſes or black cattle, and as the beſt of all land vegetables for the dunghill.

Mr. Rawſon in the ſame work alſo highly approves of, and has long practiſed, the feeding of horſes and ſpring cattle in ſummer upon clover; he has found that an acre of clover, cut and carried to the cattle and horſes in their hovels and ſtalls, will maintain double the quantity of ſtock to an acre paſtured; beſides the very great quantity of manure produced by this mode of feeding, which ſecures almoſt to a certainty the turnip crop.

Alſo in a trial made by Mr. Mure in ſoiling bullocks with winter tares, as ſtated in the Annals of Agriculture, the advantages of this practice over that of feeding in the paſtures is very fully ſhewn. The ſame ſyſtem of ſoiling has been practiſed with advantage by many others, as Mr. J. Wright, &c.

The ſame ſyſtem has been carried to a far more conſiderable extent, and with a new and quite different object, at the callico-printing works at Banniſter Hall, near Preſton, in the ſame county, under the direction and management of Charles Swainſon, eſq. Here the ſoiling with tares and clover is practiſed with a view of procuring the pure dung of the cattle which is ſo uſeful and neceſſary in this ſort of printing buſineſs, as well as for the common purpoſes, and producing a large ſupply of milk. The ſyſtem is practiſed to the extent of twenty-five cows and ſix horſes, by which a prodigious ſaving of expence in the raiſing and providing of dung is made, as well as in the procuring of hay; while the appearance and condition of the cattle are far better than in the uſual methods of managing them.

The horſes are ſome of them ſoiled upon and conſume the refuſe food from the cows, ſo that nothing is waſted or loſt. The team-horſes are kept in the ſtable, the others in a ſmall encloſure, eating their food out of racks. The litter employed is the weld which has been uſed in dyeing, but very little of it is uſed, as the pure dung of the neat cattle is a material object.

The cows are bound up in ſheds or cow-houſes, and kept properly ſupplied with theſe ſorts of green food, in conſequence of which they give large quantities of excellent milk. They are kept conſtantly ſoiled in this way during the ſummer, except while they are conſuming the after-graſs of the meadows. And it is only the trouble and attention which are required in raiſing and providing other kinds of green food for winter uſe, which is wholly incompatible with large works, that have prevented the ſame practice in feeding from being followed during the winter ſeaſon, as the great ſuperiority and advantage of green food over that of dry in the milking ſyſtem, as well as the raiſing of pure dung, are well underſtood.

The cows, though confined to the houſe during the whole of the day, are let out once or twice in that time for the purpoſe of exerciſe and water, but drink little under the ſoiling practice. There is often much advantage in varying their food, in the quantity of milk which is afforded. Cows, when tired of clover, will greedily devour tares, and theſe laſt when podded are found to be moſt excellent food in the view of producing milk. The ſame variety may likewiſe be equally beneficial in the uſe of other ſorts of crops.

It is conſidered as of material importance in this practice with milch cows, that they are kept cool and in the ſhade.

Sir Humphrey Davy thinks, that in feeding cattle with green food, there are many advantages in the practice of ſoiling, or ſupplying them with food, where their manure is preſerved, out of the field; the plants, it is conceived, are leſs injured when cut, than when torn or jagged by the teeth of the cattle, and no food is waſted by being trodden down. The cattle are likewiſe obliged to feed without making any ſelection; and in conſequence the whole food is conſumed: the attachment or diſlike to a particular kind of food exhibited by animals, affords, it is ſuppoſed, no proof of its nutritive properties or powers, as cattle at firſt refuſe linſeed cake, one of the moſt nutritive ſubſtances upon which they can be fed. See STOCK, *Choice of Food in.*

Many ſtatements, which the nature of our work does not allow our inſerting, ſufficiently prove the great benefits which may be derived from a more general introduction of this practice in all caſes where it can be had recourſe to, which are probably much more numerous than are commonly ſuppoſed; as in all places where there are lands proper for the purpoſe of raiſing the neceſſary ſorts of green crops, it may be reſorted to in the moſt ſucceſsful manner. The great cauſes which have retarded and prevented the ſpreading of the ſoiling ſyſtem of management would ſeem to be the fear of the great expence of labour that attends it, and the taking of farmers out of their uſual methods of cattle feeding. The former has, however, been ſhewn to be a mere nothing when compared with the number of animals; and the latter obviouſly deſerves no attention whatever. It is not improbable but that great benefit might alſo ariſe in many inſtances from ſoiling other ſorts of animals in this way; ſuch as ſheep, hogs, deer, &c. as vaſt quantities of manure would be produced, and at the ſame time the animals be kept in better order, and afford greater improvement and profit.

This is a method of practice that has been found, by the moſt exact trials, to anſwer perfectly both with horſes, neat cattle, and ſwine; and with cows it has been found very beneficial in the trials of Mr. Curwen and ſeveral others, as well as in other inſtances. See SWINE and TEAM.

The writer of the corrected account of the ſtate of agriculture in the county of Middleſex has, however, obſerved, in oppoſition to this ſyſtem of management, that though “it has lately been ſuggeſted by ſeveral writers, that carrying graſs into the yards, and giving it to cattle there, is more adviſeable than permitting them to collect their own food: where the party can manure half his land annually, or the whole every ſecond year, it may, it is ſuppoſed, be expected to ſupport ſuch a high degree of exhauſtion; but in other caſes, the paſture would ſoon be ſo much impoveriſhed, as to produce nothing for the owner of it to mow. Meadows which can be flooded by art at any period of ſummer, would probably, too, it is thought, admit of having their produce continually carried off: in all other caſes, ſuch a ſyſtem would, in the opinion of the writer, in a ſhort time ruin the land.”

But ſurely no rational or conſiſtent practical agriculturaliſt ever inculcated the neceſſity or utility of the practice of mowing and carrying the graſs of paſture or hay-lands to be conſumed in the farm-yards by cattle. The ſyſtem of uſeful ſoiling, ſo far as it is known to us, has been uſually confined to luxuriant crops of the artificial graſs kind, raiſed by means of tillage, and provided for by the increaſed quantity of manure which is produced and preſerved in the proceſs or practice.

“The increaſed labour and expence of ſuch a practice would alſo, it is ſaid, render it unprofitable; one man employed in that manner, with a horſe and cart, could not attend the cattle, and bring in the produce of many acres, though it would coſt a grazier in this county, annually, it is ſuppoſed, one hundred and thirteen pounds; to which ought to be added, that the manure would be waſted in ſuch a manner, as to loſe a large moiety of it; in all which ways one hundred and twenty pounds would be expended, which is a greater ſum than this practice is calculated to repay.”

It is evident, however, from what has been ſeen above, that one man can not only attend to the cattle, but convey the produce of many acres to the places where it is to be eaten, beſides doing much other work; and as to the horſes and carts which are neceſſary, as thoſe of the ſmall kind are commonly the moſt ſuitable, they will be found on almoſt all farms where ſuch a method of cattle management can be had recourſe to with any benefit. Such an imaginary charge, therefore, ſeems to be founded on no juſt grounds. And that there would be any great deal more waſte of manure in this than in other ways, is probably a mere ſuppoſition, as under good management, evaporation in hot ſeaſons would be guarded againſt, and the accumulation of it in the practice is univerſally allowed to be extremely great. There is conſequently no well-founded reaſon for concluding that the practice will not amply repay every expence attending it when properly carried on.

“The only advantage which it promiſes is, it is ſaid, to avoid the damage done by the treading of cattle: it muſt be admitted, that in wet ſeaſons and deep graſs this is conſiderable: but *a few additional acres* would, it is believed, ſupply a ſimilar quantity of herbage at a leſs expence; where that cannot be obtained, reducing the number of cattle would, it is ſaid, have the ſame effect, and might be done without incurring ſo great a diminution of profit as the foregoing one hundred and twenty pounds would certainly be.

“It is obvious, (the writer ſays, after ſtating other objections,) that this is one of the cloſet ſyſtems of ſupporting cattle, which cannot be reduced to practice beyond the extent of a very few acres, and only then, when it can be done without any additional men or horſes. If the expence of the men and teams is to be brought into the account, it will, it is ſaid, be altogether unprofitable. Such an expence would, in this county, amount, it is ſuppoſed, in fifteen weeks, to thirty-four pounds ten ſhillings; which, divided by the number of acres (ten), proves the charge to be, on each acre, three pounds nine ſhillings; or divided by the number of oxen (ſix), it would be, on each, five pounds fifteen ſhillings: add this extra expence, it is ſaid, to a long liſt of uſual and unavoidable charges, and it will ſwell the account to ſuch a ſum, as would exceed the value of the improvement of any cattle whatever.”

The ſyſtem of ſoiling animals can clearly be extended to more than a few acres, and even where additional men and horſes are required, though there will be ſeldom any occaſion for them in the practice. Nor is the expence of the men or teams employed about it any real objection, when juſtly and fairly calculated, or even that of the cattle *per* head of any account, ſo as to make it more than equal to their advancement in condition. Where no ſufficient data are given, from actual trials, it is eaſy to arrive at concluſions; but the practice and experience of farmers in the beſt cultivated diſtricts, ſet all ſuch opinions and concluſions at naught.

SOINI, in *Geography*, a town of Sweden, in the government of Waſa; 70 miles E. of Waſa.

SOINIDRO, a town of the iſland of Cuba; 75 miles E.S.E. of Havanna.

SOJOURNERS, among the *Athenians*, were permitted to dwell in the city, and follow their own buſineſs, without diſturbance, provided they obſerved all the laws and cuſtoms of the country; but were allowed no ſhare in the government. However, they were not allowed to act any thing, or manage any buſineſs in their own names, but were obliged to chooſe out of the citizens one, to whoſe care and protection they would commit themſelves, whoſe duty it was to defend them from all violence and oppreſſion. He was called *proſtates*.

SOJOWIZ, in *Geography*, a town of Bohemia, in the circle of Boleſlau; 4 miles S. of Benatek.

SOISSONS, a town of France, and principal place of a diſtrict, in the department of the Aiſne, ſeated on the Aiſne. Before the revolution it was the ſee of a biſhop, ſuffragan of Rheims, and the capital of a diſtrict, called “Soiſſonnois.” In the time of Cæſar this town was conſiderable, and called “Noviodunum.” It afterwards took its name from the Sueſſiones, who were among the laſt that remained ſubject to the Romans. At the death of Clovis I. his ſon Clothaire made it the place of his reſidence, 6½ poſts N.W. of Rheims. The place contains 8189, and the canton 14,839 inhabitants, on a territory of 125 kiliometres, in 20 communes. N. lat. 49° 23′. E. long. 3° 20′.

SOIT *fait il comme deſiré*, be it done as it is deſired; a form uſed when the king gives the royal aſſent to a private bill preferred in parliament.

SOITA, in *Ancient Geography*, a town of Aſia, in the Greater Armenia. Ptolemy.

SOITO *de Rebordoins*, in *Geography*, a town of Portugal, in the province of Entre Duero e Minho; 6 miles N. of Barcelos.

The word is ſometimes alſo uſed for the privilege of tenants excuſed from cuſtomary impoſitions.

Alſo for a quit-rent, or payment made to the lord by his tenant, for acting in quality of *ſoc-man*, or freeholder. See Socage.

SOKALLEN, in *Geography*, a town of Ruſſian Lithuania; 9 miles S. of Ragnit.

SOKASPOGE, a town of the ſtate of Georgia; 4 miles N.E. of Oakfuſkee.

SOKE, in *Rural Economy*, an ancient term, uſed to ſignify the privilege of mills, &c. By it the lord, in certain caſes, was enabled to raiſe a conſiderable rent.

Soke-*Mill*, that kind of mill which belongs to the lord or ſuperior of the manor, and at which all the tenants, and ſometimes the whole pariſh, are bound to grind their grain. Mills of this nature were once very common, and they exiſt ſtill in a few places.

SOKELY, in *Geography*, a town of Norway, in the province of Bergen; 24 miles S.W. of Romſdal.

SOKEMANS. See Socmen.

SOKER, in *Geography*, a ſmall iſland in the Red ſea; 3 miles E. of Dſjabbel.

SOKE-REEVE, in our *Old Writers*, the lord's rent-gatherer in the *ſoke*, or *ſoken*.

SOKHIO, in the *Materia Medica*, a name uſed by ſome authors for a peculiar ſpecies, if it may be ſo called, of the lignum aloes.

It is of a greyiſh colour, and ſeems to have been the blea, or outer part of the wood next the bark.

SOKO, in *Geography*, a diſtrict of Africa, on the Gold Coaſt, extending about a league along the ſea-coaſt, on the borders of the river Volta. The land is fertile, but the inhabitants are poor, and employ themſelves chiefly in fiſhing.

SOKOLMA, a town of Poland, in Volhynia; 12 miles N. of Luckow.

SOKOLOW, a town of Poland, in Podolia; 54 miles N.W. of Kaminiec.

SOKOLOWKA, a town of Auſtrian Poland, in Galicia; 20 miles S. of Lemberg.

SOKOLVOD, or Knezdo, a mountain of Croatia; 32 miles E. of Bihacs.

SOKOR ZOK, a town of Armenia, ſituated on a ſmall hill, equally diſtant from Betlis and Diarbekir, governed by a powerful, independent, and hereditary prince, who has under his orders many different tribes of Kurds, Yezedis, and Turkomans, of a martial and barbarous diſpoſition, and who, it is ſaid, can bring an army of 20,000 men into the field. The climate of this place is leſs ſevere than that of Betlis; the diſtricts are extenſive, and covered with villages, but the population of the town does not exceed 6000 ſouls. South of Zok is the town of Sahert, or *Serud;* which ſee.

SOKOTKA, a town of Lithuania; 15 miles S.W. of Grodno.

SOL, a ſyllable in the firſt elements of vocal muſic, which, in major keys, always implies the 5th above the key-note: as, *do re mi fa ſol;* or *do—ſol.*

Sol, or *Sou*, *Shilling*, in *Commerce*, a French coin, according to the old ſyſtem, which prevailed before the revolution, of billon, *i. e.* of copper with a little ſilver mixed, equal to twelve deniers, or French pence, or four liards; and the twentieth part of the livre Tournois, or pound. See Shilling.

The word is formed from the Latin, *ſolidus*, a ſhilling. Bodin is miſtaken when he derives it *à ſole*, by reaſon of the ſun ſtruck on it.

The ſol was firſt ſtruck on the foot of twelve deniers Tournois, whence it was alſo called *douzain*, a name it afterwards retained, though its ancient value was changed; the ſol having been ſince augmented by three deniers, and ſtruck with a puncheon of a fleur-de-lis, to make it current for fifteen deniers. Soon after the old ſols were coined over again, and both old and new were indifferently made current for fifteen deniers. In 1709, the value of the ſame ſols was raiſed to eighteen deniers. Towards the latter end of the reign of Louis XIV. the ſols of eighteen deniers were again lowered to fifteen. The ſol of fifteen deniers was called *ſol Pariſis*. According to the old ſyſtem, the ſilver coins in France were the ecu, or crown of ſix livres; the petit ecu, or half-crown (alſo called ecu) of three livres: pieces of twenty-four, twelve, and ſix ſous; alſo pieces of two ſous and ſix liards, or one and a half ſou, containing five parts of ſilver to nineteen of copper; and pieces (entirely copper) of one ſou, two liards, and one liard, or twelve, ſix, and three deniers. The piece of twenty-four ſous, compared in fineneſs with the Engliſh ſtandard of 11 oz. 2 dwts., is W. 0 dr. 7 dwt., its weight 3 dr. 20 gr., its content in pure ſilver is 83.4 gr., and its value in ſterling is 11¼*d.* The pieces of twelve and ſix ſous are in proportion. The piece of thirty ſous of 1791 is W. 3 oz. 8 dwt., its weight 6 dwt. 12 gr., its contents in pure ſilver 100.2 gr., and its value in ſterling 1*s.* 2*d.* The piece of fifteen ſous is in proportion.

In old authors we read of gold ſols, which were different at different times. In the time of the Salic law, the gold ſol was forty deniers; and thus it continued till the time of king Pepin, when it was reduced to twelve. Some have alſo imagined, that the French had anciently ſilver ſols.

The Dutch have alſo two kinds of ſols: the one of ſilver, called *ſols de gros*, and likewiſe *ſchelling;* the other of copper, called alſo the *ſtuyver*. See Coin.

The ſol, or ſou, is alſo a money of account and copper coin in Switzerland.

Sol, in *Aſtrology*, &c. ſignifies the ſun. Sol in Aries, &c. See Sun.

Sol, *Sun*, in *Chemiſtry*, is gold; thus called from an opinion that this metal is, in a particular manner, under the influence of that luminary.

What ſhould have been the principal inducement of torturing this metal, with ſo much violence, to obtain from it ſome medicinal virtues, Dr. Quincy obſerves, is not eaſy to be gueſſed.

Moſt, indeed, acknowledge, that gold in ſubſtance, or reduced into the ſmalleſt particles by the hammer, as in the leaf-gold, is not digeſtible in the ſtomach, ſo as to be tranſmitted into the blood, and be of any efficacy there. But there are nevertheleſs many, who are confident of its doing extraordinary matters, if reduced into a powder, by amalgamation with mercury, and by evaporating the mercury afterwards.

Zacutus Luſitanus is one of the ſmarteſt pleaders on this ſide the controverſy, againſt Muſa, Picus Mirandola, and Platerus; who, beſides many inſtances of its efficacy, urges the authority of Avicen, Serapion, Geber, and many of the Arabian phyſicians, with thoſe of other countries, and of later date. Quercetan, Schroder, Zwelfer, and Etmuller, with many other more modern practical phyſicians, have fallen into the ſame opinion. But which ſide ſoever is right, the preſent practice rejects all pretenſions to medicines from it. See Gold, in *Medicine* and *Chemiſtry*.

Sol, in the *Hermetical Philoſophy*, ſignifies ſulphur.

Sol, in *Heraldry*, denotes *or*, the golden colour in the arms of ſovereign princes.

Sol *Galiczk*, in *Geography*, a town of Ruſſia, in the government of Koſtrom; 96 miles N.N.E. of Koſtrom. N. lat. 59°. E. long. 42° 24′.

Sol *Vitchegodſk*, a town of Ruſſia, on the river Vitchega; 36 miles N. of Uſtiug. N. lat. 61° 30′. E. long. 46° 14′.

SOLA, a ſmall iſland in the Caribbean ſea; 30 miles E. of Margarita.—Alſo, a ſmall iſland among the Philippines, near the S. coaſt of the iſland of Luçon. N. lat. 13° 22′. E. long. 12° 46′.

Sola, *La*, *Pylſtart's Iſlands*, ſo called by Maurelle. See Pylstart.

SOLÆUS, in *Anatomy*. See Soleus.

SOLAGNA, in *Geography*, a town of Italy, in the Treviſan; 5 miles S. of Ciſme.

SOLAGUR, a town of Bengal; 25 miles W.N.W. of Silhet.

SOLAKI, a town of Dageſtan; 60 miles N.N.W. of Derbend.

SOLAN, a town of Africa, in Caſhna. N. lat. 16° 30′. E. long. 10°.

SOLANA, in *Ancient Geography*, a town of Aſia, in Serica. Ptolemy.

SOLAND, or Solan-*Gooſe*, in *Ornithology*. See Pelecanus *Baſſanus*.

SOLANDER's Island, in *Geography*, an iſland in the South Pacific ocean, near the S. coaſt of New Zealand, diſcovered by captain Cook in March 1770; and ſo named after Dr. Solander. It is merely a barren rock, about a mile in circuit, remarkably high, and lying full five leagues diſtant from the main. The ſhore of the main lies neareſt E. by S. and W. by N., and forms a large open bay, in which there is no appearance of any harbour or ſhelter for ſhipping againſt S.W. and ſoutherly winds: the ſurface of the country is broken into craggy hills of a great height, on the ſummits of which were ſeveral patches of ſnow; it is not, however, wholly barren, for wood was ſeen not only in the vallies, but upon the higheſt ground; but it exhibited no ſigns of being inhabited. S. lat. 46° 31′. W. long. 192° 49′. Hawkeſworth's Voy. vol. iii.—Alſo, a ſmall iſland in the Mergui Archipelago. N. lat. 10° 39′.

SOLANDERS, in *Farriery*. See Malanders.

SOLANDRA, in *Botany*, was originally deſtined by the younger Linnæus, to preſerve the memory of his friend Dr. Daniel Charles Solander, F.R.S., ſo well known in England as the companion of ſir Joſeph Banks, in his voyage round the world, and afterwards one of the librarians of the Britiſh Muſeum. He was intimately connected with the moſt eminent cultivators of natural ſcience here in England, eſpecially Ellis (ſee that article); being no leſs eſteemed for his polite and agreeable manners, than his extenſive knowledge. He died of an apoplexy, in 1782, aged 46. His learned botanical manuſcripts remain in the Bankſian library; his premature deceaſe having prevented his finiſhing, for publication, any conſiderable work, though his information enriched every thing that appeared in this country during his reſidence here. The great Linnæus, who juſtly conſidered Solander as one of his ableſt pupils, had named a *Solandra* in the 6th edition of *Gen. Pl.* but this was ſubſequently referred to *Hydrocotyle*. The genus we are now to deſcribe, muſt be conſidered as firſt publiſhed, by being repreſented on the honorary medal ſtruck in Sweden ſoon after Dr. Solander's death; and thus it takes place of the leſs certain and ornamental *Solandra* of Murray, in Linn. Syſt. Veg. ed. 14. 623, not publiſhed till 1784.—Swartz in Stock. Tranſ. for 1784. 300. t. 11. Ind. Occ. v. 1. 386. Schreb. 793. Willd. Sp. Pl. v. 1. 936. Mart. Mill. Dict. v. 4. Saliſb. Tr. of L. Soc. v. 6. 99. t. 6. Ait. Hort. Kew. v. 1. 388.—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneis affine*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, angular, with from three to five lanceolate, erect teeth, ſubſequently more deeply ſeparated, permanent. *Cor.* of one petal, thrice the length of the calyx, funnel-ſhaped; tube inflated and bell-ſhaped in the upper part, five-ribbed; limb in five roundiſh, ſpreading, reflexed, wavy, partly doubly crenate, lobes. *Stam.* Filaments five, thread-ſhaped, declining, the length of the tube, inſerted into its middle part; anthers terminal, verſatile, ſomewhat pyramidal, of two cells. *Piſt.* Germen ſuperior, oval; ſtyle thread-ſhaped, declining, longer than the ſtamens; ſtigma obtuſe, compreſſed, ſlightly two-lobed. *Peric.* Berry oval, pointed, ſmooth, of four cells. *Seeds* very numerous, kidney-ſhaped, imbedded in pulp, inſerted into a four-branched receptacle.

Eſſ. Ch. Calyx tubular, ſplitting. Corolla funnel-ſhaped, inflated, irregular; limb in five rounded, reflexed, unequal ſegments. Berry of four cells, with many ſeeds.

1. S. *grandiflora*. Great-flowered Solandra. Willd. n. 1. Ait. n. 1. Jacq. Hort. Schonbr. v. 1. 21. t. 45.—Native of Jamaica, where, according to Swartz, it occupies the clefts of rocks, and the trunks of the largeſt trees, climbing, by roots thrown out of the ſtem, to their very ſummits, from whence its long, ſpreading, leafy, dependent *branches* hang down very far, flowering in January and February, and ripening fruit in Auguſt. The plant was introduced at Kew by Mr. Maſſon, in 1781, and long known by the extemporaneous name of *Portlandioides*, given by its finder; for being treated with the uſual ſupplies of water, and a rich ſoil, it grew every year luxuriantly, but never flowered, till accidentally ſet aſide and neglected, in the dry ſtove. By ſuch management it has often flowered ſince, and Jacquin ſays it ripens fruit and ſeed at Schonbrun. The *wood* is ſpongy. *Stem* and *branches* round. *Leaves* ſcattered, moſt crowded about the ends of the branches, reflexed, ſtalked, obovate, or elliptic-oblong, acute, entire, ſomewhat undulated, ſingle-ribbed, ſlightly ſucculent, more or leſs downy, from four to ſix inches long; paler beneath. *Footſtalks* an inch long, round, downy. *Flowers* uſually ſolitary, terminal, nearly ſeſſile, very large, a ſpan long, magnificent in appearance, and delicioully fragrant. The *corolla* is cream-coloured, with a tinge of yellow; the outſide often purpliſh, and ſlightly downy; the ſegments of the limb flaccid, partly entire, partly crenate, and waved, in an elegant manner. *Fruit* ſometimes as big as a hen's egg, white, red within, of a ſweet ſubacid taſte.—The inhabitants of Jamaica know this plant by the name of the Peach-coloured Trumpet-flower. Plumier is ſaid to have left a ſketch of it, among his drawings, by the name of *Stramonium ſcandens, flore luteo.*

SOLANEÆ, the 41ſt natural order in Juſſieu's ſyſtem, the 8th of his 8th claſs. It is thus named from the Nightſhade, (ſee Solanum,) which is one of the tribe, and the order is nearly equivalent to the Linnæan Luridæ, ſee that article. We refer the reader to Gentianæ for the character of Juſſieu's 8th claſs; and to Lysimachiæ, Pediculares, Sapotæ, and Scrophulariæ, for ſome orders belonging to it.—The *Solaneæ* are thus defined.

Calyx generally in five ſegments, more or leſs deeply ſeparated, for the moſt part permanent. *Corolla* generally regular, and five-cleft. *Stamens* moſtly five, uſually inſerted into the lower part of the corolla. *Style* ſolitary. *Stigma* ſimple, or rarely cloven. *Fruit* moſtly of two cells, with many ſeeds; ſometimes capſular, of two valves, with a partition parallel thereto, as in the *Scrophulariæ*; or more frequently pulpy, with central receptacles for the ſeeds attached to the middle of the partition, at each ſide, and uſually prominent, ſo as to ſeparate each principal cell of the berry internally into two parts, or, by a ſtill further imperfect ſubdiviſion, into more. *Corculum* of the ſeed curved, lodged in a farinaceous *albumen*. *Stem* herbaceous or ſhrubby. *Leaves* alternate; in ſome inſtances there are two floral ones from the ſame point. *Flowers* variouſly diſpoſed, often extra-axillary, that is, placed near the ſide of the inſertion of the leaves, not ſpringing from their boſoms.

The firſt ſection, with a capſular or dry fruit, conſiſts of *Celſia*, *Verbaſcum*, *Hyoſcyamus*, *Nicotiana*, and *Datura*.

The ſecond, with a berry, of *Triguera* of Cavanilles, which we have recently diſcovered to be the very identical *Verbaſcum Oſbeckii* of Linnæus, a plant that no ſubſequent botaniſt could ever make out; (ſee VERBASCUM and TRIGUERA;) *Jaboroſa* of Juſſieu; *Mandragora* of Tournefort; *Atropa*; *Nicandra* of Adanſon, which is *Atropa phyſaloides* of Linnæus; *Phyſalis*; *Witheringia* of l'Heritier; *Aquartia*; *Solanum*; *Capſicum*; *Lycium*; and *Ceſtrum*.

Section third contains three genera, reckoned akin to the former; theſe are *Bontia*, *Brunfelſia*, and *Creſcentia*. With theſe laſt the true *Solandra* is, as Juſſieu ſuſpected, to be aſſociated. See SOLANDRA.

SOLANILLOS, in *Geography*, a town of Spain, in New Caſtile; 23 miles E. of Guadalaxara.

SOLANO, a ſmall iſland near the coaſt of Peru. S. lat. 12° 20′.—Alſo, a river of Mexico, which runs into the Pacific ocean, N. lat. 10° 18′.

SOLANOIDES, in *Botany*, a name given by Tournefort to the *Rivina* of Linnæus, on account of its reſemblance to SOLANUM; which ſee. See alſo RIVINA.

SOLANOS, in *Meteorology*, a name given to winds, which, blowing over an extenſive tract of highly heated land, become ſo very drying, ſcorching, and ſuffocating, as to produce dreadful effects, and are often felt in the deſerts of Arabia, in the vicinity of the Perſian gulf, in the interior of Africa, and in ſome other places.

SOLANTA, in *Geography*, a town on the N. coaſt of the iſland of Sicily, which gives name to a cape and bay: 8 miles E. of Palermo. N. lat. 38° 9′. E. long. 13° 36′.

SOLANUM, in *Botany*, an ample genus, compriſing various kinds of Nightſhade, and other deadly plants, along with the eſculent Tomato, Egg-plant, and even the valuable Potatoe, owes its name, according to ſome authors, to its comforting quality, ſuch authors ſuppoſing the word to have originated from *ſolamen*. This indeed might apply to the potatoe, could that poſſibly have been in the contemplation of thoſe who gave the name. The common derivation *a ſole*, from the ſun, carries no more conviction along with it; nor can we for a moment admit the true orthography to be *Sulanum*, from *Sus*, becauſe the plant is uſeful to ſwine. It is far more prudent to leave *Solanum* among the few ancient names whoſe ſource cannot be traced.—Linn. Gen. 100. Schreb. 134. Willd. Sp. Pl. v. 1. 1025. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 256. Prodr. Fl. Græc. Sibth. v. 1. 154. Ait. Hort. Kew. v. 1. 396. Brown Prodr. Nov. Holl. v. 1. 444. Purſh v. 1. 156. Juſſ. 126. Tourn. t. 62. Lamarck Illuſtr. t. 115. Gærtn. t. 131. (Lycoperſicon; Tourn. t. 63. Melongena; ib. t. 65.)—Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cut half way down into five, erect, acute, permanent ſegments. *Cor.* of one petal, wheel-ſhaped; tube very ſhort; limb large, plaited, ſpreading, ſomewhat reflexed, cut half way down into five acute ſegments. *Stam.* Filaments five, awl-ſhaped, very ſmall; anthers large, erect, oblong, converging, ſlightly connected, of two cells, opening each by a terminal pore. *Piſt.* Germen ſuperior, roundiſh; ſtyle thread-ſhaped, longer than the ſtamens; ſtigma obtuſe. *Peric.* Berry roundiſh, ſmooth, marked with a dot-like ſcar at the ſummit, of two cells, divided by a fleſhy receptacle, which is convex at each ſide. *Seeds* numerous, roundiſh, lodged in ſoft pulp.

Eſſ. Ch. Corolla wheel-ſhaped. Anthers ſlightly connected, opening by two terminal pores. Berry ſuperior, of two cells.

Notwithſtanding the rude and irregular habit of this genus, the flowers are often ſo handſome as to attract much notice, and the fruit is, in ſome caſes, very ſtriking and ornamental. The ſtem is branched, herbaceous or ſhrubby, ſmooth, hairy or prickly. Leaves alternate, ſimple or compound, lobed, cut or entire; ſometimes prickly. Infloreſcence often lateral, and extra-axillary. Corolla blue, purple, white, or yellow. Fruit yellow or red, rarely black or white. The herbage is fœtid, narcotic, and dangerous. Flowers without ſcent. Fruit often very nauſeous, and in no inſtance eatable without dreſſing.

The ſpecies are diſpoſed in three ſections. The fourteenth edition of Linn. Syſt. Veg. contains forty-ſix; Willdenow has eighty-three. Some new ones are added by Brown, Purſh, Aiton, &c. We ſelect the following, adding ſeveral unknown to the author whoſe arrangement we adopt.

Section 1. *Without prickles.* Forty-four ſpecies in Willdenow; two Britiſh.

S. *laurifolium.* Laurel-leaved Nightſhade. Linn. Suppl. 148. Willd. n. 1.—Stem arboreous, unarmed. Leaves ſtalked, ovate-oblong; downy beneath. Panicle terminal, repeatedly forked, divaricated. Calyx briſtly on the inner ſide.—Native of the vaſt foreſts of Surinam; unknown in the European gardens; nor has a figure of this ſpecies appeared. The *branches* are woody, round and ſmooth. *Leaves* near a ſpan in length, entire, pointed, veiny; ſhining, and ſlightly downy, above; clothed with ſoft depreſſed hairs, ſpreading from all the fineſt veins, beneath. *Footſtalks* an inch long, rather ſilky. *Panicle* repeatedly forked and racemoſe, widely ſpreading, compoſed of innumerable *flowers*, of which the *calyx* only remains on our ſpecimens, which is ſmall, with five acute ſpreading ſegments, moſt hairy or briſtly within. *Berries* black, the ſize of a Black Currant.

S. *verbaſcifolium.* Mullein-leaved Nightſhade. Linn. Sp. Pl. 263. Willd. n. 2. Ait. n. 1. Jacq. Hort. Vind. v. 1. 5. t. 13. (S. maximè tomentoſum, ſpinis carens, virginianum; Pluk. Almag. 351. Phyt. t. 316. f. 1.)—Stem ſhrubby, unarmed. Leaves alternate, ſtalked, ovate, denſely downy, entire. Corymbs terminal, divided. Calyx with five ſhort teeth.—Native of the Weſt Indies, from whence Cateſby communicated it to Miller. The plant is preſerved in ſome curious ſtoves, and flowers in ſummer. The *branches*, *ſtalks*, *calyx*, and both ſides of the *leaves*, are hoary, denſely clothed with cloſe ſtarry down. *Flowers* white, with yellow *anthers*, far inferior in ſize and beauty to the Potatoe-bloſſom. The ſhallow diviſions of the *calyx*, and the cloſe, not ſhaggy, *hairs* of the ſtalks and branches, diſtinguiſh it from the *auriculatum* hereafter deſcribed.

S. *inæquale.* Unequal-leaved Woolly Nightſhade.—Stem ſhrubby, unarmed. Leaves in pairs, ſtalked, ovate, entire, denſely downy; unequal at the baſe. Cluſters lateral, divided. Calyx of the fruit in five deep ſegments.—Gathered in New Granada by Mutis. The younger Linnæus confounded

founded the ſpecimen with *S. verbaſcifolium*, from which it eſſentially differs in the inequality of the two ſides of each *leaf*, at the baſe, and eſpecially in the *infloreſcence*. The twin racemoſe *flower-ſtalks* ſpring laterally from the intermediate ſpaces of the branches, between the *leaves*, and two of the latter always grow together, nearly from the ſame point. Whether the *calyx* of the *flower* be deeply divided, we cannot, becauſe of its woollineſs, determine; but that of the *fruit* is ſeparated into five lanceolate ſegments, to the very baſe. *Berry* the ſize of a red currant, beſprinkled with ſtarry hairs.

S. *auriculatum*. Ear-leaved Nightſhade. Ait. ed. 1. v. 1. 246. ed. 2. n. 2. Willd. n. 3. (S. mauritianum; Scop. Del. Inſubr. v. 3. 16. t. 8.)—Stem ſhrubby, unarmed. Leaves ſtalked, ovate, pointed, entire; very ſoft above; acute at the baſe. Stipulas heart-ſhaped. Corymbs terminal, divided. Calyx cloven half way down.—Native of Madagaſcar, the Mauritius, and the Eaſt Indies. A tall *ſhrub*, with the habit of *S. verbaſcifolium*, but larger; the pubeſcence of the *ſtalks* uſually more ſhaggy; the greener upper ſurface of the *leaves* remarkable for a velvet-like ſoftneſs; the under white and woolly. *Calyx* ſeparated half way down into five broad ſegments, which are not deeper in the *fruit* than in the *flower*. The *ſtipulas* are often wanting, but the ſpecies is ſufficiently diſtinct.

S. *Pſeudocapſicum*. Shrubby Winter-cherry Nightſhade. Linn. Sp. Pl. 263. Willd. n. 6. Ait. n. 3. (Amomum Plinii; Lob. Ic. 265. Ger. Em. 361. Pſeudocapſicum; Dod. Pempt. 718. Strychnodendron; Beſl. Hort. Eyſt. æſtiv. arb. t. 14. f. 1.)—Stem ſhrubby, unarmed. Leaves lanceolate, wavy, ſmooth. Umbels lateral, ſeſſile.—Native of Madeira. One of our popular hardy greenhouſe plants from Gerarde's time to this day. The *ſtem* is buſhy, a yard high. *Leaves* ſtalked, ever-green, about two inches long. *Flowers* few together, drooping, white, with orange *anthers*. *Fruit* ſcarlet, globoſe, the ſize of a ſmall cherry.

S. *diphyllum*. Two-leaved Nightſhade. Linn. Sp. Pl. 264. Willd. n. 10. Ait. n. 4. Jacq. Ic. Rar. t. 322. Coll. v. 2. 331. (S. americanum, ſtrychnodendro accedens, fructu medio, antè maturitatem, quaſi fiſſo; Pluk. Phyt. t. 111. f. 4.)—Stem ſhrubby, unarmed. Leaves in pairs, elliptic-oblong, ſmooth; one ſmaller than the other. Flowers cymoſe, oppoſite to the leaves.—Native of the Weſt Indies, from whence it was brought early to this country; but is only occaſionally kept in ſtoves, rather for curioſity's ſake than otherwiſe, being leſs ornamental than the laſt, with ſmaller *flowers* and *fruit*, and much more tender.

S. *Dulcamara*. Woody Nightſhade, or Bitter-ſweet. Linn. Sp. Pl. 264. Willd. n. 15. Fl. Brit. n. 1. Engl. Bot. t. 565. Curt. Lond. faſc. 1. t. 14. Woodv. Med. Bot. t. 33. Fl. Dan. t. 607. (Amara dulcis; Ger Em. 350.)—Stem ſhrubby, twining, unarmed. Upper leaves haſtate. Cluſters cymoſe, drooping, oppoſite to the leaves. Fruit elliptical.—Native of moiſt buſhy places throughout Europe, from Norway to Greece, flowering in ſummer. The branching zigzag *ſtems* climb upon other ſhrubs, and diſplay their elegant bunches of violet-coloured *flowers*, each of whoſe ſegments has two green dots at the baſe, in an elegant manner. The ſcarlet pellucid *berries* are alſo beautiful, though of a bitter and dangerous quality. The *leaves* are ovate, acute, uſually ſmooth, on long ſtalks, ſome ſimple, others haſtate, rarely diſtinctly auricled. The bark and roots are ſaid to be bitter, with a ſubſequent ſweetneſs. The young ſhoots have been recommended, in decoction, for rheumatic and ſcorbutic diſeaſes. We have ſometimes doubted whether this might not be the κυκλαμινος ἑτερα of Dioſcorides, a much diſputed plant: but the flowers are neither white, nor fragrant, as he deſcribes them. We readily concur with Willdenow in believing the Linnæan β, figured in Dill. Elth. t. 273. f. 352, to be a diſtinct ſpecies, nor do we doubt its being the *quadrangulare*, hereafter mentioned.

S. *Seaforthianum*. Lord Seaforth's Nightſhade. Andr. Repoſ. t. 504. Ait. Epit. 374.—Stem ſhrubby, twining, unarmed. Leaves ſimple or ternate, ovate, pointed, ſmooth. Panicles lateral, drooping, compound. Corolla without dots.—Native of the Weſt Indies, from whence it was brought by the late earl of Seaforth. This beautiful ſpecies is ſaid to ſucceed beſt in a conſervatory. Its general appearance reſembles the laſt, but the large pendulous *panicles* of numerous pale-purple *flowers*, deſtitute of green dots, are very different, and extremely ornamental on a trellis. The *infloreſcence* often ſeems terminal, but is properly lateral. Of the *berries* we have no information.

S. *ſcandens*. Climbing Surinam Nightſhade. Linn. Suppl. 147. Amoen. Acad. v. 8. 253. Willd. n. 17.—Stem twining, unarmed. Leaves ovate; heart-ſhaped at the baſe; downy beneath. Panicle terminal, cymoſe. Calyx ſmooth on the inſide.—Native of Surinam. The *leaves* betray a conſiderable affinity to our firſt ſpecies, *laurifolium*, but the downineſs of their under ſurface conſiſts of little, forked or ſtarry, ſcattered hairs, not of ſimple ones proceeding in double rows from each vein. The *branches* moreover are long and flaccid, apparently herbaceous; and the *calyx* is not briſtly within, but nearly ſmooth on both ſides. *Corolla* downy, divided almoſt to the bottom. Lower half of the *ſtyle* hairy. *Berries* the ſize of a cherry.

S. *quercifolium*. Oak-leaved Nightſhade. Linn. Sp. Pl. 264. Willd. n. 20. Ait. n. 6. (S. foliis quernis; Feuill. Peruv. 722. t. 15.)—Stem ſomewhat herbaceous, angular, zig-zag, rough-edged, erect, unarmed. Leaves pinnatifid. Cluſters cymoſe.—Gathered by Feuillé, on the mountains of Valparaiſo, in Chili. Linnæus raiſed the plant at Upſal, from ſeeds ſent by Juſſieu, but it has only lately found its way to the Engliſh gardens. The *root* is thick, fleſhy, and perennial. *Stem* four or five feet high, branched, leafy, with ſeveral unequal angles, that are rough, with minute ſharp tubercles. *Leaves* regularly pinnatifid, of five or ſeven bluntiſh, entire, rather diſtant lobes, nearly ſmooth; their long *footſtalks* ſlightly winged. *Flowers* drooping, violet, with yellow *anthers*; their *corolla* broader than that of *S. Dulcamara*. *Berries* red, ovate.

S. *radicans*. Rooting Nightſhade. Linn. Sp. Pl. 264. Willd. n. 22. Ait. n. 8. Linn. fil. Dec. 1. 19. t. 10.—Stem ſomewhat herbaceous, unarmed, roundiſh, proſtrate, nearly ſmooth, taking root. Leaves pinnatifid. Cluſters cymoſe.—Native of Peru. Very nearly related to the laſt, but differing in its proſtrate creeping *ſtem*, whoſe angles are leſs marked, and almoſt ſmooth. The ſegments of the *leaves* are never more than five. *Cluſters* ſimple. *Flowers* fewer and ſmaller, white; purpliſh beneath. *Berries* yellow, globoſe or two-lobed.

S. *laciniatum*. Cut-leaved Nightſhade. Ait. ed. 1. v. 1. 247. ed. 2. n. 7. Willd. n. 21. Br. n. 4. Curt. Mag. t. 349. (S. aviculare; Forſt. Prodr. 18. Pl. Eſcul. 42.)—Stem ſomewhat ſhrubby, unarmed, ſmooth. Leaves linear-lanceolate, undivided or pinnatifid, entire, ſmooth. Cluſters lateral, corymboſe. Calyx cloven half way down. Segments of the corolla emarginate. Stamens ſpreading. Berry oval.—Native of New Zeeland, New South Wales, and Van Diemen's land. A greenhouſe ſhrub, introduced by ſir J. Banks in 1772. The *leaves* are dark green, nearly ſeſſile; ſometimes quite undivided, ſometimes deeply pinnatifid, on the ſame or a different plant; their length from four to eight inches. *Flowers* purple, large and handſome, with rounded notched ſegments. *Anthers* yellow, ſoon widely ſpreading from each other. *Fruit* yellow, the ſize of a large plum, acid, ſweetiſh, but with a diſagreeable flavour. Forſter ſays the inhabitants, as well as the ſmall birds, of New Zeeland, greedily devour this fruit, nor did the European voyagers entirely reject it.

S. *corymboſum*. Corymboſe Peruvian Nightſhade. Ait. ed. 1. v. 1. 248. ed. 2. n. 11. Willd. n. 26. Jacq. Ic. Rar. t. 40. Coll. v. 1. 78. Retz. Obſ. faſc. 5. 22.—Stem unarmed, ſomewhat ſhrubby, ſmooth. Leaves ovato-lanceolate, entire; tapering at the baſe. Flower-ſtalks lateral, branched, corymboſe.—Found by Dombey at Lima, growing near waters. M. Thouin ſent ſeeds to Kew in 1786, when we ſaw the plant flowering in the ſtoves at Paris, in Auguſt. Its beauty ſcarcely exceeds our wild *S. nigrum*. The *flowers* are copious, ſmall, purpliſh. *Cluſters* ſeveral together, on a common corymboſe ſtalk, oppoſite to each leaf. *Berries* ſcarlet, the ſize of a ſmall pea.

S. *quadrangulare*. Quadrangular African Nightſhade. Linn. Suppl. 147. Willd. n. 27. Thunb. Prodr. 36. (S. Dulcamara β; Linn. Sp. Pl. 264. S. craſſifolium; Lamarck Dict. v. 4. 284. S. dulcamarum africanum, foliis craſſis hirſutis; Dill. Elth. 365. t. 273. t. 352.)—Stem ſhrubby, unarmed, angular, rough. Leaves ovate; undivided, or with angular lobes. Panicles terminal, cymoſe.—Found by Thunberg, at the Cape of Good Hope. Cultivated by Sherard at Eltham, and therefore entitled to a place in Mr. Aiton's work. The figure of Dillenius is very characteriſtic, as to the *foliage* and *flowers*, but does not expreſs the remarkably angular *ſtem*, except towards the top of the ſpecimen. Hence it has been overlooked with regard to this plant. The *branches* in Thunberg's two ſpecimens before us are irregularly quadrangular, very rough, with callous points and briſtly hairs. *Leaves* ſtalked, fleſhy, ſmooth, except at the edges, an inch or inch and half long, obtuſe, ovate; either quite entire, or on luxuriant ſhoots, furniſhed with one or two large, prominent, tooth-like lobes at each ſide. *Flowers* larger, paler, and leſs expanded than in our *Dulcamara*; the points of the *corolla* hairy.

S. *bonarienſe*. Tree Nightſhade. Linn. Sp. Pl. 264. Mant. 205. Willd. n. 29. Ait. n. 12. (S. bonarienſe arboreſcens, papas floribus; Dill. Elth. 364. t. 272. f. 351.)—Stem ſhrubby, nearly unarmed. Leaves ovate-oblong, waved and ſinuated, rough. Fruit half the diameter of the flowers.—Native of Buenos Ayres. Raiſed from ſeed by Sherard in 1726, or thereabouts, and now a frequent greenhouſe plant, of a tall buſhy habit, eſteemed for its copious large white *flowers*, with orange *anthers*. The *leaves* are from three to ſix inches long, beſprinkled with little ſtarry rigid hairs. *Flower-ſtalks* corymboſe, oppoſite to the leaves. *Berries* yellow, ſcarcely half an inch broad. The young *ſtems* are prickly in the lower part, and indeed not unfrequently in the upper, ſo that this ſpecies would ſtand better in the ſecond ſection.

S. *macrocarpon*. Large-fruited Nightſhade. Linn. Mant. 205. Willd. n. 30. Ait. n. 13. (S. caule inermi ſuffruticoſo, foliis oblongo-ovatis ſinuatis utrinque glabris, floribus alaribus; Mill. Ic. v. 2. 196. t. 294. Lycoperſicum arboreſcens, foliis angulatis, fructu aureo; Plum. Ic. 219. t. 224. f. 2.)—Stem ſhrubby, unarmed. Leaves wedge-ſhaped, waved and ſinuated, ſmooth. Fruit thrice the diameter of the flowers.—Native of Peru. A ſtove-plant, cultivated by Miller, and flowering in ſummer. This is of a larger ſize, and ſtouter habit, than the laſt, with which Linnæus long confounded it. The *flowers* are blue; their *corolla* ſmaller, with more pointed ſegments, and the *corymbs* leſs compound, than in *S. bonarienſe*, but the *fruit* is ten times as large, ſupported by a ſhort thick ſtalk.

S. *tuberoſum*. Common Potatoe. Linn. Sp. Pl. 265. Willd. n. 31. Ait. n. 14. (S. tuberoſum eſculentum; Bauh. Prodr. 89. Battata virginiana; Ger. Em. 927. Papas Peruanorum; Beſl. Hort. Eyſt. autumn. t. 27. f. 1.)—Stem unarmed, herbaceous. Leaves interruptedly pinnate, entire. Flower-ſtalks ſubdivided.—Native of Peru. Gerarde ſays he received roots from Virginia, which ſucceeded well in his garden. No ſimilar acquiſition was ever more important to this country. The *herbage* is annual, impatient of cold, buſhy, with copious roughiſh *leaves*, pinnate in a lyrate form, with very ſmall intermediate leaflets. *Flowers* panicled, large, purpliſh or white, drooping, very handſome. *Fruit* globoſe, purpliſh.—For the different varieties, uſes, and cultivation of this valuable plant, ſee POTATOE.

S. *Lycoperſicum*. Tomato, or Love-apple. Linn. Sp. Pl. 265. Willd. n. 33. Ait. n. 15. (Poma amoris; Camer. Epit. 821. Ger. Em. 346. Beſl. Hort. Eyſt. autumn. t. 1, 2.)—Stem unarmed, herbaceous. Leaves interruptedly pinnate, cut. Cluſters deeply divided, leafleſs. Fruit ſmooth.—Native of South America. A tender annual, cultivated in England ever ſince Gerarde's time, for the ſake of its large, variouſly-ſhaped, ſcarlet or orange *fruit*, which many people eſteem a great luxury, either in ſoups; or broiled with pepper and ſalt, as an addition to roaſt-meat, or game. In the hotter parts of Europe, the Tomato has more acidity and briſkneſs of flavour, and is therefore the more welcome in ſuch climates. It has alſo the reputation of being ſtimulant, or aphrodiſiacal. The *root* is fibrous. *Herb* of rank growth, weak and decumbent, fœtid, glutinous, downy. *Leaflets* acute, coarſely cut and toothed, with a double ſeries of ſmall ſtalked intermediate ones. *Flowers* yellow, in large divided bunches. *Fruit* ſhining, pendulous, very ornamental.—Whether Jacquin's *Pſeudo-lycoperſicum*, with its ſimple *cluſters*, and ſmall globular *fruit*, be a diſtinct ſpecies, we greatly doubt; ſee his Hort. Vind. v. 1. t. 11. Linnæus did not diſtinguiſh it. Nor have we abſolute confidence even in *S. peruvianum*, Linn. Sp. Pl. 265. Willd. n. 35. Jacq. Coll. v. 2. 284. Ic. Rar. t. 327, diſtinguiſhed by its bracteated or leafy *cluſters*, and ſomewhat downy *fruit*. Its *root* indeed is perennial, and the herbage more compact, neat, and hoary, than the common Love-apple.

S. *multifidum*. Ragwort-leaved Nightſhade. Lamarck Dict. v. 4. 287. Illuſtr. t. 115. f. 3, not 2.—Stem herbaceous, unarmed, winged. Leaves doubly pinnatifid, obtuſe. Panicle cymoſe.—Gathered by Dombey, in ſandy ground at Lima. The *root* is fibrous, apparently annual. *Stem* twelve or eighteen inches high, branched, ſpreading, leafy, bordered at each ſide with an entire, uninterrupted wing. *Leaves* ſucculent, rather downy, elegantly ſubdivided, decurrent; all their lobes obtuſe. *Flowers* white, or purpliſh, ſeveral together, in long-ſtalked, terminal, cymoſe or forked *panicles*. *Corolla* but ſlightly divided.

S. *nigrum*. Common or Garden Nightſhade. Linn. Sp. Pl. 266. Willd. n. 39. Fl. Brit. n. 2. Engl. Bot. t. 566. Fl. Dan. t. 460. Curt. Lond. faſc. 2. t. 14. Woodv. Med. Bot. t. 226. (S. hortenſe; Ger. Em. 339. Camer. Epit. 812. Matth. Valgr. v. 2. 415.)—Stem herbaceous, unarmed, erect. Leaves ovate, with tooth-like angles. Umbels lateral, drooping.—Native of cultivated and waſte ground in all parts of the world. *Root* annual. *Stem* buſhy, more or leſs angular. *Leaves* ſcattered, ſtalked, ovate, ſlightly downy; elongated at the baſe; either entire, wavy, or coarſely toothed, at the margin. *Umbels* lateral, not quite oppoſite to the leaves, ſolitary, ſtalked, compoſed of numerous ſmall white *flowers*, with yellow *anthers*. *Berries* the ſize of currants, uſually black, but occaſionally yellow, even in England, according to Hudſon. Authors enumerate ſeveral varieties of this ſpecies, differing in the more or leſs angular, and ſomewhat criſped or toothed, *ſtem*, and more hairy or ſmoother *herbage*. Willdenow ſays theſe are permanent, but we can ſcarcely define the diſtinctive marks of each. Several of them are exhibited in Dill. Elth. t. 274 and 275.

S. *anguſtifolium*. Narrow-leaved Nightſhade. Lamarck Dict. v. 4. 291.—Stem unarmed, ſomewhat herbaceous. Leaves ſtalked, linear-lanceolate, obtuſe, entire, ſmooth. Cluſters lateral, divided.—Gathered by Commerſon at Buenos Ayres. The *ſtem* is branched, leafy, ſomewhat angular, zigzag, or perhaps rather twining. *Leaves* alternate, uniform, about two inches long, and a quarter or half an inch broad, with one rib, and a few lateral connected veins. *Flowers*, in our ſolitary ſpecimen, certainly not terminal, but oppoſite to a leaf, in a divided *cluſter*, not numerous, on long partial ſtalks. *Calyx* hemiſpherical, nearly or quite ſmooth, with very unequal broad ſegments. *Corolla* blue, half an inch wide, finely downy at the outſide.

S. *betaceum*. Beet-leaved Nightſhade. Cavan. Ic. v. 6. 15. t. 524. Ait. n. 18. Andr. Repoſ. t. 511.—Stem ſhrubby, round, unarmed. Leaves ovate, pointed, fleſhy, ſmooth; heart-ſhaped at the baſe; wavy at the edges. Cluſters lateral, ſtalked, divided, pendulous.—Probably a native of South America. Seeds were ſent, in 1803, by Cavanilles, from the Madrid garden to the writer of this article. The plant is gigantic, twelve feet high or more, fleſhy, very fœtid when touched or bruiſed, growing luxuriantly if turned out againſt a ſouth wall in ſummer, but not of ſufficient beauty to excite general notice. Some *leaves* meaſure twenty inches in length, and fifteen in breadth. The *flowers* are ſmall in proportion, not quite ſo big as a potatoe-bloſſom, but more deeply divided, light purple with yellow *anthers*.

S. *Melongena*. Egg-plant Nightſhade. Linn. Sp. Pl. 266. Willd. n. 41. Ait. n. 19. (Melongena; Camer. Epit. 820. Matth. Valgr. v. 2. 424. Mala inſana; Ger. Em. 345. Fuchſ. Hiſt. 533. Melauzana fructu pallido; Beſl. Hort. Eyſt. autumn. t. 3.)—Stem herbaceous, unarmed. Leaves ovate, wavy, clothed with ſtarry down. Flower-ſtalks deflexed, ſwelling. Calyx moſtly unarmed. Fruit ovate, ſmooth and even. Native of tropical climates; cultivated in various parts of the world by means of hot-beds or ſtoves, for the ſake of its *fruit*, which reſembles a large egg, and is uſually of a pure poliſhed white, though ſometimes tinged with violet. It is eaten in Italy, Spain, and other warm countries, like the Tomato. We have under the article MELONGENA, traced the origin of that word, and ventured to derive from thence the frightful appellation of *Mala inſana*, Mad-apples, given to the fruit in queſtion, which it appears not particularly to deſerve. The *herbage* is branched, clothed with ſtarry, not very denſe, pubeſcence. *Flowers* purpliſh, large, drooping, lateral or axillary, not many together. Segments of the *calyx* lanceolate, or nearly linear; ſometimes prickly.—Gerarde ſays of theſe apples, "the people of Toledo eat them with great devotion, being boiled with fat fleſh, putting to it ſome ſcraped cheeſe, which" (the apples) "they do keep in vinegar, honey, or ſalt pickle, to procure luſt."

Section 2. *Prickly*. Thirty-eight ſpecies in Willdenow; none Britiſh.

S. *inſanum*. Prickly Mad-apples. Linn. Mant. 46. Willd. n. 45. (S. pomiferum, magno fructu ex albo et atropurpureo nitente, foliis et calyce ſpinoſis; Pluk. Phyt. t. 226. f. 3. S. pomiferum, fructu nigro ſpinoſo; Moriſ. ſect. 13. t. 2. f. 2.)—Stem prickly, herbaceous. Leaves ovate, ſinuated, denſely downy. Flower-ſtalks deflexed, ſwelling. Calyx armed with ſtrong prickles. Fruit oblong, ſmooth, furrowed.—Native of tropical climates. Linnæus originally confounded this plant with *S. Melongena*, of which it may, after all, be only a thorny variety. *Trongum hortenſe*, Rumph. Amboin. v. 5. 238. t. 85, ſeems rather to belong to the *Melongena*.

S. *mammoſum*. Nipple Nightſhade or Bachelor's Pear. Linn. Sp. Pl. 267. Willd. n. 51. Ait. n. 24. Purſh n. 3. (S. barbadenſe ſpinoſum, foliis villoſis, fructu aureo rotundiore, pyri parvi inverſi formâ et magnitudine; Pluk. Phyt. t. 226. f. 1. Pomum Sodomæ; Merian. Surin. 27. t. 27.)—Stem hairy, prickly, herbaceous. Leaves heart-ſhaped, lobed and angular; prickly and hairy on both ſides. Fruit pointed.—Native of the Weſt Indies. An annual ſtove-plant, which may perhaps have been frequently introduced, and ſoon again loſt. The whole of the *herbage* is very villous, the *footſtalks*, and ribs of the *leaves*, more eſpecially, armed with formidable ſtraight yellow thorns. *Flowers* pale blue, in ſmall lateral cluſters, with a hairy *calyx*, and large *anthers*. *Fruit* ſolitary, yellow, about two inches long, ovate with a point. Merian ſays it is very poiſonous to men and beaſts. Mr. Purſh found this ſpecies on the ſea-coaſts of Virginia and Carolina, its ſeeds, as we ſhould ſuppoſe, having floated thither.

S. *virginianum*. Virginian Nightſhade. Linn. Sp. Pl. 267. Willd. n. 55. Ait. n. 25. Purſh n. 4. (S. americanum laciniatum ſpinoſiſſimum; Dill. Elth. 360. t. 267. S. annuum nigricans virginianum ſpinoſiſſimum latè ſe ſpargens, flore cæruleo, glabrum; Pluk. Phyt. t. 62. f. 3.)—Leaves pinnatifid, with ſinuated obtuſe ſegments, ciliated, very prickly on both ſides, as well as the herbaceous upright ſtem, the ſtalks, and the calyx. Fruit globoſe.—On road-ſides, and in ſandy fields, from Virginia to Carolina, flowering in July. *Purſh*. A tender biennial with us. The *root* is fibrous. *Stem* branched, erect, ſpreading. *Leaves* three or four inches long, deeply ſinuated and cut, minutely fringed, but otherwiſe the whole plant is deſtitute of pubeſcence, though every where copiouſly armed with awl-ſhaped pale-yellowiſh thorns, ſometimes near an inch long. *Flowers* lateral, diſtant from the leaves, ſimply racemoſe, blue. *Fruit* ſmall, globoſe, variegated with green and white.

S. *Jacquini*. Jacquin's Nightſhade. Willd. n. 56. Ait. n. 26. (S. virginianum; Jacq. Coll. v. 2. 285. Ic. Rar. t. 332.)—Leaves pinnatifid, with ſinuated obtuſe ſegments, ſmooth, very prickly on both ſides, as well as the decumbent, ſpreading, herbaceous ſtem, the ſtalks, and the calyx. Fruit globoſe.—Native of the Eaſt Indies, iſle de Bourbon, &c. Sent to Kew by ſir Joſeph Banks about 1804. A tender annual, flowering in September and October. Very nearly akin to the laſt, but the decumbent *ſtem*, and ſmooth edges of the *leaves*, are, in conſideration of its oriental origin, ſuppoſed to indicate a ſpecific difference. Some ſtarry hairs occur on the young *leaves*, and extremities of the *branches*. The *fruit* is the ſize of a gooſeberry, variegated with light and dark green. *S. xanthocarpum*, Schrad. Sert. Hannov. t. 2, is too nearly related to this to be conſidered as more than a variety.
